desires to enter his sons for his own professions or aspires to give them access to the public service of the country. To a matter-of-fact person, the ideal of knowledge for its own sake has few attractions, and his greatest concern is that the money he invests in the education of his children should bring return in the form of enrichment of his own profession, or that their service to the State should be adequately remunerated. Such a man has very little use for the type of education now imparted in our schools and colleges, which in his judgment leads nowhere. One of the criticisms passed on modern education is that the cultural and social advantages of higher education are beyond the reach of the man of humble means. Of all the questions which will engage the earnest and immediate attention of the projected Board, the most important ones appear to us to be the statutory grant, the education of the poor man's children and the problem of the pass-man.

The Government of India contemplate the creation of a number of Committees to assist the Advisory Board in the investigation of relevant problems, and perhaps the most vital question that will confront the Board, when brought into being, must relate to Finance. There should be established a Committee of Finance of moderate dimensions, of independent character and possessed of adequate powers to act as a link between Government and the Board. We would prefer to call this body, Committee of Reference. It should enjoy statutory power for the purpose of elucidating and correlating expenditure on the several grades of education, besides exercising advisory and supervisory authority in connection with the financial allocation in each province. The advice of this Committee in regard to the assignment of contributions by the Central and Provincial Governments to educational and university purposes should be adopted, which would thus secure unification of the financial policies of the different administrative authorities. If such a body is to be efficient it must include independent men of affairs, who could pronounce impartially upon conflicting claims, and also persons who are cognizant of the needs and general practice of the universities and have a genuine interest in their welfare and progress. We emphasise the importance of the Committee of Reference because it is borne in upon us that the clue to the majority of the educational and university problems and the condition of their reforms must ultimately be finance, and unless the Committee secures adequate statutory financial contribution, progress will be impossible.

It is obvious that since the appearance in the political field, many of the social classes in India are anxious to participate in the benefits of higher education, to which they are attracted as an instrument in the task of preparation for their new and arduous responsibilities. They regard higher education as an indispensable equipment for the part that they desire to play in national life. The extension of the franchise, the increasing association with local self-governing bodies and the organisation of social groups have given them power which they rightly think they can exercise for the advantage of their own class and also for that of the nation, if this power is accompanied by knowledge. Our schools and colleges are now filled with the sons of these social classes, because they think that they have a right to share in the national cultural inheritance, and it is appropriate that special facilities and preferential treatment should be offered to them. But in recent times, the discussion of the question of creating special advantages for them has suffered from the defect that little or no attempt has been made to distinguish between the various classes among whom the term "poor" is treated as synonymous with that of "backward". We attribute the failure of some modern educational expedients aiming at reform, to this confusion of ideas, and the fact is that plans suitable to one section have been found almost inapplicable to the other. The changes in the economic life of modern society and in the intellectual progress of the nation necessitates a more scientific distinction of the communities; for the wage-earning classes who could properly have been called "poor" half a century ago have now acquired wealth, while those who may fairly be termed "backward" did not at that time aspire to higher education. But in so far as both of them represent particular strata in the national life, it is obvious that they should have free access to the advantages of higher education.

Perhaps the most delicate and difficult task for the Advisory Board will be to formulate their proposals for the working-class education, to encourage the desire of the industrial communities to profit by

The Educational Advisory Board.

THE formation of a Central Advisory Board of Education, foreshadowed by Sir G. S. Bajpai at the last session of the Legislative Assembly at Delhi, is, in our opinion, an urgent necessity. In recent times, the academic problem has assumed new and perhaps complex shapes, and in its solution the Government of India might naturally desire to rely on the advice and assistance which this expert body is competent to place at their disposal. When Government abolished the Bureau of Education in 1923, their influence on the formation and execution of the educational policy of provinces practically disappeared and the new Board is obviously intended to restore that influence. It is desirable—means will no doubt be found for it—that the Educational Advisory Board should be so constituted that it will fit into the general framework of Federal Administration, since it is proposed to make it a department of Central Government. Otherwise the experience and progress obtained by the Indian States in the sphere of education will lose contact with the machinery devised for British India. Educational progress in India is hampered by periodic financial inhibitions, and the first task of the Board must be to secure a statutory grant for giving effect to its recommendations.

Among the various factors which have rendered the academic problem increasingly complex in India, mention must be made of the immense expansion of scientific knowledge with its reactions on the social and economic life of the country, the vastly increased demand for higher and technological education, the wider conception of the duties of the modern universities and the emergence in the body politic of social communities which had previously remained indifferent. We are not impressed by the zeal of educationists for the constitutional reform of their institutions, however important they may be to the inner life of their administration, for the outside world always measures the efficiency of the machinery by its results, unmoved by its structural beauty. The problem of the public is comparatively simple. The man in the street

academic discipline. If this desire is genuine, then it seems to us that its satisfaction should not exclusively be left to private enterprise or to a somewhat precarious combination between state and municipal interests, but that it should be recognised and regulated by the Board or by one of its Committees. Should there be a working-men's school and college in every important industrial centre, where education is imparted free of cost? In answering this question, it should be borne in mind that gratuitous benefactions do not promote a sense of self-respect, nor is their value fully appreciated. For the creation of such institutions for the children of humble means, the Board must seek and find assistance from public-spirited benefactors to supplement its other resources. Education is a slow process and naturally therefore it does not excite popular imagination or stir public sympathy. The recent enhancement of school and college fees and dues, owing largely to the shrinkage of grants to these institutions has placed impediments in the way of poor young men who wish to take their share in the academic and social advantages of higher education. If in spite of subsidies in pecuniary or other shapes which the poor disappointed young men might otherwise obtain, there are features in the higher general and professional institutions, which act as a deterrent to the entry of such students. We do not subscribe to the theory that education is meant only for those who have sufficient means and intelligence to profit by it. If a man is sufficiently rich he is often indifferent to education. The purpose of education is to seek those whose intellectual powers are dormant and to stimulate them for the advantage not only of their own class but also for that of the nation. The problem of educating the poor is a national task to which the proposed Advisory Board must give serious attention.

In the way of broadening the avenues for the admission of wider classes to the benefits of higher education, we are met with two problems, *viz.*, examinations and pass-men. If it could be proved that examinations by the qualities that they test, are a valuable adjunct to a young man's education, we might face all the unsparing criticisms which the public heap upon them. Examinations are jumbled together with an uncertain multiplicity of standards with neither consistency nor uniformity. A man who is rejected in one college or university may obtain admission to another where he may pass with honours. This is a question which no scheme of reform undertaken by the Central Advisory Board can overlook, and which cannot be permanently ignored.

The question of examination in the last resort raises the issue of the pass-man and of his position in the field of higher education. We have no concern here with the pass-man whose idleness is responsible for his poor academical achievements but we have every consideration for the other type of pass-man whose honest endeavours have resulted only in very modest performance. It should be remembered before judgment is pronounced on such a student, that he is entirely ignorant of his own mental capabilities. He has inherited these and education cannot replace them, but can only polish them. It is ignorance of this fundamental fact that must account for all the denunciation of these young men and for opinions frankly expressed that the standard of higher education should be sufficiently stiffened to exclude them from its advantages. The Universities have obviously no use for such young men, and the employer passively accepts the verdict of the academic bodies in considering his employability. It seems to us that this judgment is as harsh and hasty, as his rejection is unsound and unwarranted. If the Universities expend their energies and resources on the creation of an intellectual oligarchy, then they cease to be national institutions, and may have to forfeit their claims to be supported by national revenues.

A great injustice is perpetrated when the idle pass-man is taken to be the type of the pass-man in general, and when the sins of the individual are visited upon the class. We shall cheerfully accept the reproach of being Philistine or reactionary, if we can succeed in impressing upon the public mind that the first concern of higher education is to instruct and enlighten the pass-man. If our universities are to continue to deserve public support, they have few more important duties to perform than to give a good general education to the man of poor capabilities. To convert him into an enlightened and useful public servant is as honourable a task of our educational institutions as it is to discover and foster eminent talents, and it is a fact that many of the men, who in later life have reflected the greatest credit on their education, have been those who never took more than a pass degree. We do not believe

in the soundness of the argument that the universities are exclusively for brilliant men, for we do not see any reason why pass and honours men should not exist side by side. We conceive that it is in such co-existence and happy mingling of all talents and social qualities favouring good fellowship and toleration, that the service of the universities to the nation resides.

The Educational Advisory Board when it deals with the question of reforming the educational system in India, will be confronted with the difficult task of framing suitable proposals for educating the poor man and the pass-man, and the task, however difficult, must be satisfactorily solved.

"Science and Culture."

WE have pleasure in offering a warm welcome to *Science and Culture*, a new monthly journal of natural and cultural sciences, the first issue of which has reached us by the courtesy of the editor, and whose aim is to promote the cause of science by spreading scientific knowledge among the public. It is further explained that publication is promoted by a non-profit corporation of "some eminent scientists and educationists of India," whose identity will doubtless be revealed in a subsequent issue.

The subject-matter is varied and interesting. Following an editorial introduction which rapidly sketches outstanding events in the historical development of Indian civilisation, there comes a long and informing article on "Bengal Rivers and their Training" by Dr. N. K. Bose, who wisely advocates establishment of a river physics laboratory resembling those already operating in Western countries, where schemes connected with river-control may be tested before adoption. An article on the "Ultimate Constituents of Matter" by Professor M. N. Saha deals comprehensively and lucidly with modern views of atomic architecture, and concludes with an imposing list of the fundamental particles involved. Rai Bahadur Ramaprasad Chanda, under the title "Aryan, Indo-Aryan and Dravidian" traces the various authorities for different forms of *bhakti*, while "Some Reactionary Consequences of Psychoanalysis" are indicated by Col. Owen Berkeley Hill. A short contribution on "Susruta and Early Hindu Anthropometry", by Dr. Panchanan Mitra is followed—abruptly as it may seem to some readers—by "Safety of Electric Installations in India" from Professor B. C. Chatterjee.

Other features are book reviews, obituary notices, a full description of the Indian Statistical Institute's foundation and purpose, a report of the U.P. Academy of Sciences April meeting, and letters to the editor. Support is given to the view of Lord Rutherford as expressed in his letter to *The Times* dated April 29, 1935, concerning retention of Professor Kapitza by the Soviet Government, and a useful outline of the distinguished captive's technical ingenuity is presented. Treatment of the subject would have gained piquancy—and perhaps proportion—if Lord Rutherford's contribution had been supplemented by the letter of Professor H. E. Armstrong, who considers that the restoration of Professor Kapitza to his homeland, so far from being a calamity, is merely a blessing in fancy dress; but then it must be remembered that this chemical veteran on a recently previous occasion stoutly opposed himself to the principle of imported professors.

From this brief survey it will be recognised that *Science and Culture* covers a wide range of material, and incidentally it may be stated that the printing and paper are excellent. It remains to consider whether the treatment of the subjects chosen is calculated to achieve the declared purpose of the promoters, namely, "dissemination of scientific knowledge amongst the public". A rough classification of the literate public in relation to scientific knowledge would reveal two main groups, namely, specialists in one or more branches, and a generally well-informed public whose members desire to keep themselves aware of such scientific discoveries and principles as may be assimilable without previous training in science. *Nature* and the *Scientific American* are probably the best known journals appealing to these two groups, respectively, and throughout the past three years we have consistently endeavoured to meet the needs of the former group in this country, with strict avoidance of partisan or territorial bias. Some aspects of *Science and Culture* are so similar to the corresponding features of *Current Science* that we confess to misgiving that its promoters have judged us and found us wanting. Actually, there is very little of the material presented in this first issue for which we would not gladly have

found space in our own columns. The question therefore arises in our mind, is there a large enough public for two similar journals ; because, if not, we fear that both must languish, under-nourished in both material and support. On the other hand, there is ample room for a journal popularising science, old and new. Therefore, while welcoming *Science and Culture* we take leave to hope that future issues may devote themselves more definitely to the declared policy of its promoters, and expand on lines complementary to—rather than competitive with—*Current Science.*

Nation Building and Scientific Research.*

EARLY during the Great War, in 1915, His Majesty's Government formed a Committee of the Privy Council for Scientific and Industrial Research, who were entrusted with the task of establishing a close link between science and industry. In the course of the next two years, this organisation developed into the Department of Scientific and Industrial Research under whose auspices a great number of researches of national importance are being carried out. The researches have an intimate bearing on some aspect of national life or industry. The cost of these investigations is being borne by co-operating firms in an ever-increasing measure, thereby showing that industry is appreciating the value of scientific research. The design of ship's hulls, the effect of waves on the resistance and pitching of ships, effect of wind resistances, the behaviour of rudders and the improvement of propellers—all problems connected with the national industry of shipping, are being investigated. The Building Research Station is conducting investigations on the design of steel frame buildings, on methods of increasing the resistance of concrete and mortar to chemical attack, on heating and ventilation problems, on limes, bricks and clays and on cast concrete products—problems closely connected with the life of the nation. The Department has also interested in the development of new high temperature alloys, in discovering new outlets for low grade coals and in the problems of storage and transport of fruits, vegetables, fish and meat, which are of vital importance in securing an adequate supply of wholesome food for the nation. Interesting work seeking an answer to the question "why does one flour from one kind of wheat produce better bread and dough than another ?" is being done by the Flour Millers' Research Association. The National Physical Laboratory is largely concerned with testing and standardisation of products manufactured by industrial concerns. The Leather Research Association, the Paint Research Association, the British Scientific Instrument Research Association, the Food Manufacturers' Association and other Research Associations are all co-operating with the Department of Scientific and Industrial Research in a programme of Nation-building acitvity, to the great advancement and prosperity of the nation as a whole.

* Report of the Department of Scientific and Industrial Research for the year 1933-34.

The Artificial Preparation of the Male Sex Hormone.

By Professor L. Ruzicka,

Technical High School of Zurich (Switzerland).

THE male sex hormone may be defined as a chemical compound produced in the testicle, and which in the male organism promotes the growth and function of the sex organs and glands, and also the development and maintenance of the secondary sex characteristics and sex instinct. The discovery of this hormone resulted from successful experiments on castrated male animals, in which the atrophy of the sex characteristics and organs was cured by implantation of the testicles of other adult animals. The first experiments in this direction date as far back as 1849, *i.e.*, long before there existed a science of hormones, when Berthold (Göttingen) successfully implanted fresh testicles into capons.

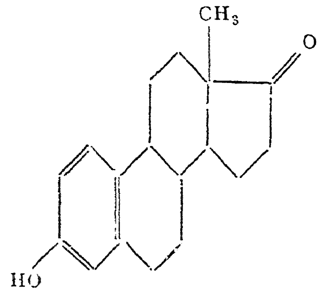
In 1929 Gallagher, Koch and Moore (Chicago) succeeded for the first time in preparing a really effective testicular extract which exhibited, in castrated animals, effects similar to those formerly obtained by grafting fresh testicles. These investigators also worked out the first practical biological test for the detection of the male sex hormone. It is the so-called capon test, which was subsequently improved by Funk, Laqueur and others, and which is based on the principle that the stunted comb of a capon increases in size by the injection of the male sex hormone, such increase being roughly proportional to the quantity of hormone injected. We call a capon unit the quantity of hormone which, with a definite technique, produces an increase of about 20% in the surface area of the comb.

With the help of this method, Butenandt (Göttingen) isolated in 1931 a male sex hormone in crystalline form from the urine of men; the injection into a capon of 0·3 to 0·4 milligrammes of the said hormone, in fractional doses, in the course of a few days produces a 20% increase in the surface area of the comb. The isolation of this hormone, called androsteron, is extremely laborious and up to the beginning of 1933 only 25 mg. of it had been isolated, for which quantity 50,000 litres of urine were required. Butenandt was able to establish that androsteron is a saturated oxyketone having the formula $C_{19}H_{30}O_2$ or $C_{19}H_{28}O_2$, and possessing four rings, although an exact chemical investigation was not possible at that time owing to the difficulty of obtaining sufficient quantities of the hormone. It was, however, possible to form a hypothetical picture of the probable structural formula of androsteron on the basis of the knowledge of the follicular hormone (theelin, œstrin) acquired in the meantime.

Following the discovery in 1923 of Allen and Doisy's test for the ovarian hormone, Butenandt and Doisy succeeded, independently and almost simultaneously in 1929, in isolating theelin in a crystalline form from the urine of pregnant women.

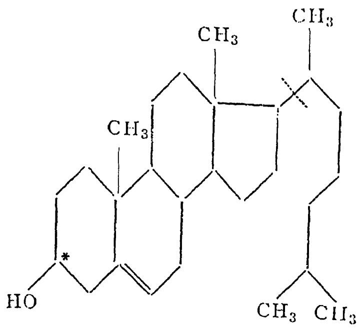
The chemical investigation of this substance by Doisy, Butenandt, Marrian and Cook, led to the assignment of formula I.

The simple manner in which this formula can be derived from cholesterol supports its correctness.



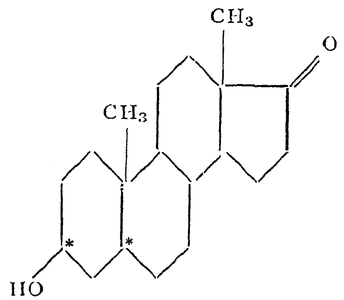
I

Theelin

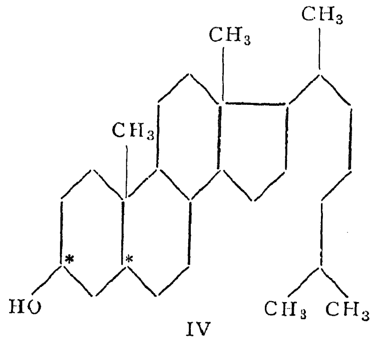


II

Cholesterol



III
Androsteron



IV
Dihydrocholesterol and stereoisomeric sterols

It is only necessary to consider that the terminal six ring of cholesterol is dehydrogenated with the formation of a phenol ring, and further, that the long side-chain is completely split off by oxidation with the formation of a ketone group.

Assuming that androsteron is also derived from cholesterol, the formula $C_{19}H_{30}O_2$ leads to the structural formula III which Butenandt proposed in 1933, as an intermediate product in the course of the hypothetical conversion of a hydrogenated sterol into theelin. The formation of a substance corresponding to formula III from hydrogenated sterol, requires only the splitting off of the long side-chain, in the same way as theelin is considered to be formed in the body by the oxidative degradation of a dehydrogenated sterol.

In view of the great difficulties which were to be expected in an attempt to determine the exact constitution of androsteron by entirely analytical methods, the author, together with his assistants, M. W. Goldberg, Jules Meyer, H. Brüngger and E. Eichenberger, decided to approach the question from another angle. An attempt was made to prepare the hormone artificially by following as closely as possible the method which nature probably uses for producing it in the body.

It was first of all necessary to investigate the question of the most suitable material to be used for the proposed work. We have discussed above the hypothesis of the derivation of theelin from cholesterol. However, up to now there are no facts at all showing that theelin is stereochemically identical with cholesterol. Further, in the artificial preparation of androsteron it was necessary to take into consideration the steric structure at the two positions marked with an asterisk in formula III. All hydrogenated sterols hitherto known differ one from another by a different steric position at these two carbon atoms. Four different stereo-isomers of the formula IV are known: dihydrocholesterol, epi-dihydrocholesterol, koprosterol and epi-koprosterol. We have included all these stereo-isomers in our investigations. Before the splitting off of the side chain, the hydroxyl groups were protected by acetylation from the action of the chromic acid used as the oxidising agent. It must be emphasised, that according to the statements in the literature, it was very improbable that a ketone of the type of androsteron could result from the oxidation of an acetylated sterol corresponding to formula IV. This improbability has certainly deterred, up to now, other investigators from employing this exceedingly simple method for the solution of the problem of the male sex hormone. However, our optimism proved to be justified. By oxidation of the acetates of the 4 sterols named, we were able to isolate the corresponding 4 oxyketones. The oxyketone derived from epi-dihydrocholesterol proved to be identical in every respect, chemically, physically and physiologically, with the natural androsteron. On the other hand, the other three isomers are distinctly different from androsteron.

Although there was from the beginning a certain probability that androsteron might belong to the sterol group, no one could have expected that it was derived from epi-dihydrocholesterol. Girard, for instance, had considered the hypothesis of lithocholic acid being the mother-substance from which androsteron originates, while Butenandt thought koprosterol more feasible. No one had previously imagined the existence of a derivative of epi-dihydrocholesterol (or of epikoprosterol) in nature.

A comparison of the physiological action of the 4 stereo-isomeric oxyketones $C_{19}H_{30}O_2$ shows the importance of the steric

configuration for the hormone character. Whereas with androsteron (both natural and artificial) a capon unit amounts to 0·07 mg., one injection a day being made during six consecutive days, one unit of the oxyketone derived from di-hydrocholesterol is 0·5 mg. The two oxyketones derived from koprosterol and its epimer were ineffective in daily doses of 1 mg.

The synthetic preparation of androsteron permitted for the first time the complete elucidation of the constitution of a sex hormone. This is a rare case of the elucidation of the constitution of a natural product of intricate composition, by the artificial preparation of the substance before anything was known about the structure of the carbon skeleton.

In this case the method of elucidation was just the reverse of that usually employed: the first detailed publication of Butenandt on the chemical reactions of androsteron which appeared two months after our communication of the synthetic preparation contains no mention of a degradation product of androsteron which might have been identified with a compound of a known constitution.

The greater accessibility of synthetic androsteron permits the investigation of the question of whether there is only one male sex hormone, or if several compounds together are responsible for the effects observed. Butenandt has already discovered a second male hormone in the urine, dehydro-androsteron, which acts in the same manner as androsteron on the capon's comb, but is distinctly weaker. There are also several female sex hormones all of which, however, exhibit a weaker action than theelin. According to our present knowledge, theelin suffices for the production of the effects of the ovarian hormone. The results obtained up to now with androsteron do not contradict the assumption that it can exhibit all the effects which one expects from the testicular hormone. Let us now describe briefly the most important physiological investigations, which have been carried out by E. Tschopp in the "Ciba" Laboratories in Basle.

The capon test shows that an overdose of androsteron causes an exceedingly pronounced increase in the size of the comb. For example, by painting the comb (according to Fussgänger's technique) daily for ten days with a $1^0/_{00}$ solution of androsteron we observed that the surface of the comb was increased sevenfold.

Furthermore, painting with a $0·5\ ^0/_{00}$ solution of androsteron, the site where later the comb grows on newly hatched chickens........causes, after a few weeks, the appearance of a comb of approximately the same size as that of cocks having attained their full development.

From a clinical point of view, it is interesting to note that with capons in which too small a portion of testicle has been preserved for the stunted comb to be able to grow, temporary injections of androsteron cause a prolonged growth of the comb. In completely castrated capons, on the contrary, the comb stops growing on cessation of androsteron treatment, whereupon a gradual atrophy of the comb to its initial size takes place. Such effects have already been observed following the administration of testicular extracts. In certain cases of testicular hypofunction, androsteron can act as a "hormone fillip" to stimulate the inactive generative glands into new activity. Investigations with mammals in that connection will be of great importance.

Furthermore, in castrated male rats, it was possible to obtain with androsteron a complete cytologic regeneration of the atrophied seminal vesicles (positive test according to Lœwe-Voss). Finally the "wedding dress" picture of the male small fish called *Rhodeus amarus*, which is obtainable with testicular extracts, could also be produced with androsteron. All the experiments which have been carried out in the past with the various extracts exhibiting the action of the male sex hormone, and especially with testicular extracts, will be repeated with synthetic androsteron, which will subsequently also be tested clinically. These experiments will show whether androsteron, or any of its derivatives possessing stronger physiological properties, can completely play the rôle of the male sex hormone.

Locust Research Work in India.

By Rao Sahib Y. Ramachandra Rao, M.A., F.R.E.S.,
Locust Research Entomologist to the Imperial Council of Agricultural Research, Karachi.

I. Introductory.

DURING the last decade, locusts have, in many parts of the world, been so much in the limelight that they hardly stand in need of introduction. During the years 1929 and 1930 especially, there were not many days on which mention was not made of them in the Indian Dailies, either in regard to their flights or the damage done by them to crops. Nor are locusts to be counted as one of the recent upheavals of the modern age. Their history apparently dates back to hoary antiquity. They are mentioned in the Bible, and formed one of the plagues of ancient Egypt. In early Sanskrit literature, references are made to them as one of the recognised calamities of the people. The immensity of the swarms, whose countless myriads often form clouds hiding the sun from the face of the earth, the dramatic suddenness of their appearance, and the terrible severity of their onslaughts, have all combined to infuse a feeling of helplessness and awe in the mind of primitive man, with the result that incursions of locusts have from time immemorial been considered to be of the nature of an act of God. Indeed, the Indian cultivator, be he Moslem or Hindu, often expresses himself unwilling to lift his hand against these pests, ruinous though they may be to his food-crops, as he believes the visitation to be a manifestation of Divine Wrath, which he dare not resist.

II. India's Locusts.

Few people are unfamiliar with grasshoppers, which may be found jumping about on the surface of lawns and fields. Locusts differ very little from them either in their general form, structure or habits, except for the fact that they often occur in large communities, which move about from place to place in gregarious swarms. There are several different species of locusts in the world, each of which has its own more or less restricted area of distribution. Not taking into account half a dozen species of Indian grasshoppers, which are known to increase in numbers periodically and cause immense damage to crops, there are only three species of true locusts in India, of which one, *Locusta migratoria*, though occurring widespread over the length and breadth of this country in its solitary phase, has, for some hitherto unaccountable reason, been very rarely recorded in its swarming condition. The other two, *viz.*, *Patanga succincta*, L.—the Bombay Locust,—and *Schistocerca gregaria*, Forsk.—the Desert Locust,—have in the past appeared in enormous swarms over large areas of India and caused a great deal of destruction to agricultural crops. Of the two, the Bombay Locust affects mostly the peninsular region of India. From the information available, mainly Lefroy's account in his *Memoir* on the Bombay Locust, this locust would appear normally to be a denizen of the forest areas of the Western Ghat ranges of the Bombay Presidency, whose flights may spread in years of heavy multiplication far and wide, as far as Guzerat to the north, as far as Central India and Hyderabad, and even Bihar and Orissa in some years, to the east, as far as Madras Deccan to the south, and upto Ratnagiri and Goa to the west. On the other hand, the Desert Locust is, *par excellence*, the Locust of North-West India. During years of outbreak, it infests chiefly Baluchistan, Sind, Punjab, the North-West Frontier, Rajputana, United Provinces and parts of Central India, but in years of extraordinary activity its flights may reach as far as east Assam and as far south as Madras Deccan. The Desert Locust is by far the more important of the two, for, the range of its spread is much wider, the periods of its outbreak are more frequent and prolonged, and the extent and degree of damage to crops is on the whole much greater. The scheme of Locust Research carried on under the auspices of the Imperial Council of Agricultural Research is concerned at present only with the Desert Locust.

III. The Origin and Scope of the Present Scheme.

Although locust outbreaks have been fairly frequent in the past, and have often been serious enough to engage the attention of a huge staff and lead to the expenditure of large sums of money in connection with control work in a great many districts of North-West India, it is surprising how little had been recorded about the central facts of its life. There were but vague and

indefinite notions as to wherefrom the swarms originated or how they responded to changes in the environment. Except for the excellent account given by E. C. Cotes in his Report on "the Locust of North-West India", 1890, no comprehensive survey of the movements of locusts in India had been made during the various locust cycles of the past. The reasons for this are not far to seek. The incursions of locusts are periodic and even during outbreaks, their appearance is definitely seasonal in most places. While they are aggressively evident during times of invasions, and while the Government as well as the public are feverishly active with the carrying out of control measures against them, sooner or later they disappear from the areas of infestation, and before long they become a mere memory. People feel relieved at their non-appearance, and take no further interest in them till they are back once again menacing agriculture.

The provincial entomologist, who is naturally occupied with and interested in the pests of his own province, attends to a study of locusts and to their control while they are active within the limits of his province, but cannot of course be expected to continue his researches when they have retreated beyond the limits of his jurisdiction. On the other hand, in the desert regions of Baluchistan and Rajputana, where the locust appears to linger on during the periods of its non-activity, no entomological staff is existent to study the question. This would appear to be the main reason why so little is known of the life-economy of the Desert Locust and why the problem has been so little investigated. In the case of a pest of this description whose distribution is not confined to a single province or country and whose powers of spread by direct flight are so enormous, a proper study of its life-habits or migration can obviously be undertaken by an organisation working under the ægis of a Central Government.

After a long period of quiescence lasting over six years, the Desert Locust appeared all of a sudden in Sind and Rajputana in August–September, 1926 and bred in enormous numbers. thereby starting the last great cycle of 1926–1931. The peak of the attack was reached in the years 1929–30, when almost all the provinces of North-West India were infested and the resulting swarms reached eastwards as far as Assam and southwards as far as Hyderabad (Deccan). It was in the thick of the against this formidable outbreak of pest in the rich agricultural areas of Pu United Provinces and Sind, that the Gov ments of the various provinces of Nort India realised what serious proportions locust menace could assume and how perfect the existent knowledge of the lo problem in India was. As a result question was included in the agenda of Board of Agriculture in India, which at Pusa in December, 1929. After discussion, resolutions were passed at meeting recommending (1) the forma of a Locust Bureau under the auspice the Imperial Council of Agricultural search for the prompt collection, colla and distribution of locust intelligence wi Indian limits, (2) the institution of a Lo Research Scheme in India for conduc research in regard to control methods, locating the permanent breeding grou and the migration routes of the locus India, and for working out its bionon thoroughly, and (3) the organisation control methods on efficient and co-ordin lines in all the affected states and provi including the central storage of anti-lo material by the Central Government.

Action was taken by the Governmen all these recommendations in due co The Central Locust Bureau of the Imp Council of Agricultural Research bega function early in February, 1930 and been of great service in giving pro warnings to areas subject to infestation regard to the activities of locusts. Entomologist—Rai Sahib G. R. Dutt, B. was also attached to the Central Bu from May 1930 to March 1932. Arra ments were also made for the storage some anti-locust material at Delhi.

Last but not least, a Locust Rese Scheme financed by the Imperial Co of Agricultural Research began to func from December, 1930 under the charge M. Afzal Husain, Esq., M.A. (Cantab.), M I.A.S., Entomologist to the Governmen Punjab, as Locust Research Entomolo to the Imperial Council of Agricult Research with head-quarters at Lyallp Through the kind permission of the Pu Department of Agriculture, the Lo Research Scheme had the benefit of all facilities of the up-to-date laboratories of Entomological Section at Lyallpore, various problems connected with the history and bionomics of the locust

worked out during the years 1931, 1932 and 1933, by specially appointed staff under the direct guidance of Mr. Afzal Husain. Much difficulty was, however, felt during 1932 and 1933 in obtaining live material for experimentation owing to the disappearance of locust swarms by the end of 1931.

In regard to the location of the locust breeding grounds, a special touring staff was recruited in January 1931 for carrying out locust surveys of the desert areas in Baluchistan, Sind and Rajputana, and placed under the writer, as Deputy Locust Research Entomologist to the Council, with headquarters at Quetta. As specimens of the solitary phase of the locust were discovered by the staff during the tours conducted in 1931 in the coastal areas of Mekran, a special Field Research Station was established at Pasni in the midst of typical locust breeding grounds in January 1932 and placed under the charge of Dr. K. R. Karandikar as Assistant Locust Research Entomologist for studying the ecology of the solitary phase locust in its natural habitat.

Since April, 1933 Mr. Afzal Husain's services were required by the Punjab Agricultural Department for the Principalship of the Punjab Agricultural College. He could not, therefore, continue to be in charge of the Locust Scheme, but undertook to continue his work on bionomics at Lyallpore, with the help of a research grant from the Imperial Council of Agricultural Research and the responsibilities of the charge of the rest of the Scheme devolved on the writer from that date.

IV. PROGRESS MADE IN THE LOCUST INVESTIGATION WORK.

Locust research has been in progress for over four years at the moment of writing, and it may be stated without exaggeration that quite a large amount of work has been accomplished. It may also be mentioned that the work done every year has been scrutinised by the Locust Advisory Committee of the Imperial Council and has had, therefore, the advantage of their approval and advice in most particulars. The progress made may be dealt with under the following heads:—

1. *Survey Work.*—In 1931 survey work was mostly confined to Baluchistan where most of the districts subject to locust infestation were examined, especially Mekran, Kharan, Lasbela and Chagai. A part of the Bahawalpore desert area was also examined. In 1932, survey staff was reorganised, and work was pushed on by means of a motor-lorry purchased by the Imperial Council for touring purposes, and various centres in the Indus Valley of Sind, parts of Baluchistan, and the Dera Ghazikhan District, and parts of Bahawalpore, Bikaner, Jodhpur, Cutch and Western India States were visited. Wherever roads were non-existent, as in the interior of the Indian Desert, tours were carried out on camel-back. In this manner, quite a number of places were located in which locusts of a non-gregarious character were noticeable. During 1933, the plan of survey work was changed. The work was confined to the areas where locusts of a non-migratory type had been located, and the places were visited periodically throughout the year in order to note the effect of the seasons on the activities of the solitary locusts. In 1934, the same plan was pursued, but with the addition of two Desert Observation posts where intensive observations on locusts were to be carried out in addition to the recording of certain simple bioclimatic data.

Results of Survey Work.—While locust swarms easily attract regular attention and their movements may be expected to be reported by existing official organisations, the existence of locusts in their non-gregarious form is apt to be missed altogether unless specially trained staff is employed to look for them in their natural habitat. Owing to the enormous extent and the comparative inaccessibility of the area to be examined, and the sparsity of the locust population, it would be rather futile to expect a high degree of thoroughness from the small staff employed. The results actually obtained have, however, been sufficient to indicate that, in certain cases, specimens of locusts of what looked like the solitary type were either the remnants of the swarms of 1931 or their descendants. It was also noticed that at present locusts are either entirely absent or are very sparse in many of the places where they were found abundantly in 1932. The observations made have also shown that as in the case of the migratory type, the non-gregarious type of locust is dependent on rainfall for oviposition and breeding, and there appears to be some evidence to show that, like the migratory phase, the non-gregarious type is capable of making migrations over short distances though only as individuals. On the whole, it would rather look as if locusts were gradually disappearing from the areas

of the Indian Desert, and the present situation rather indicates that the 'rek' areas of the Mekran Coast are possibly more important from the locust-breeding point of view.

In addition to making observations on locusts the staff engaged on survey work have also as far as possible attended to the collection of the flora and the fauna of the tracts examined.

2. *Bionomics.*—The various known facts of the life-history and the habits of the locust are ultimately referable to the fundamental peculiarities of its structure and to the nature of its response to the impact of its environment. An exact knowledge of the nature and extent of the responses exhibited by the locust can only be obtained by an experimental study conducted under clearly defined conditions; and the results of studies would be valuable, not only for offering an explanation in regard to the activities of locusts under natural conditions, but also for devising efficient control measures. Valuable work on these lines has been done at Lyallpore in regard to various points in the life-history of the locust, *viz.*, pairing, oviposition, post-embryonic development, effect of crowding and other conditions on the colouration, etc., of hoppers, number of broods in the year, the effect of various tropisms, etc. The results of these studies are now under publication by Mr. Afzal Husain.

3. *Ecological Work.*—Most of the work on the life-history and habits of the locust published in the past is referable to the gregarious phase of its existence, and very little is on record in regard to its solitary phase. Since the areas around Pasni are apparently some of the true breeding grounds of the Desert Locust, the data collected during the last three years, in regard to the behaviour of the solitary locust in response to fluctuations of environmental conditions incident to seasonal changes, should doubtless be of great value. The central problem of these ecological studies in the elucidation of the conditions under the influence of which the change of phase—*viz.*, from solitary to the gregarious—would occur in nature. From the Locust Research point of view, the importance of a breeding ground would depend on how far conditions favouring the building up of the initial swarms of an outbreak are present, in which case alone it would function as an outbreak centre.

From the experience gained so far, it is evident that seasonal rainfall is by far the most important factor in the life-economy of the solitary phase locust. Breeding can take place only if there is rainfall, and a building up of the population would become possible only if an acceleration of breeding and a rapid succession of generations are brought about by the persistence of the requisite favourable conditions of weather.

4. *Study of Past Outbreaks.*—The memory of the serious locust infestation which lasted for nearly six years from 1926 to 1931 is possibly still fresh in the minds of most people in North-West India. This cycle was preceded by a period of about six years, roughly from 1920 to 1925, in which there was no general infestation, and we are apparently now in a similar non-locust period which began from 1932 and has already lasted over three years at the present moment. From the data at present available it is difficult to say when this period would end and the next locust cycle would commence. In this connection, a study of the past invasions is of great importance and all attempts have been made to secure reliable data on the subject. It has, however, to be stated that past records on locusts have in most cases not been preserved, and the information obtainable in such as are existent is very fragmentary in character. In certain exceptionable cases, however, as in that of the season and crop reports published in the Gazettes of Punjab, Sind and Bombay, fairly detailed and continuous information is available from the year 1869, and these have been extracted, collated and studied. In certain other instances also, *e.g.*, the records of the Jaisalmer and Kalat States, detailed information was obtainable in regard to some years. A study of the old records has shown that there have been locust cycles during the following years since 1869: 1869 to 1881, 1889 to 1907, 1912 to 1919 and 1926 to 1931, the intervals being periods of locust disappearance. During years of outbreaks, it would appear that swarms are, during the earlier months of the year, active mostly in areas of winter and spring rainfall, such as Baluchistan and parts of the Punjab, Afghanistan and Persia, and lay eggs and breed there. The adult locusts produced by these broods would appear to commence their flights during the months of April, May and June, the general direction being eastwards towards Sind, Punjab and Rajputana, where

they breed after the receipt of monsoon rains. The resultant fliers would appear to fly during the autumn months, partly further east towards Bengal and Assam or to the south, and partly back to the west towards Baluchistan and Persia. The east-bound flights appear ultimately to perish while the west-bound ones are able to breed during the spring months in Baluchistan. It would also appear that the infestation is prolonged if this circulatory system of locust flight is kept up, and that the break-down of the cycle is probably brought about by the failure of broods due to unfavourable conditions of weather in one or other of the breeding areas.

The data collected from the various files have been extracted and arranged and are being mapped out month by month for the various years, and attempts are being made to correlate the movements with available meteorological data.

V. PRESENT POSITION OF THE WORK.

Much ground has already been covered, but there is yet much work to be done.

In regard to bionomics, progress of work has been impeded mostly for want of material for experimentation, and experiments will be resumed when there is sufficiency of material. The question of sex-maturation of the locust is specially important and needs being tackled. Experiments in regard to control measures will also be undertaken when sufficient material is available.

As to survey work, it is necessary that work should be continued until a decisive answer is obtainable to the question as to which of the areas in which the locust has been found in the non-gregarious state are really important in the production of swarms. It is also necessary to determine the exact conditions under which the transformation into the gregarious phase would take place in nature. In case it is definitely proved that there are outbreak centres within Indian limits, it would be imperative to undertake a trial of control measures on the breeding grounds to determine the best methods of tackling the pest in an early stage and thus nip the evil in the bud. When the migration routes followed by swarms during periods of infestation in India have been properly studied and plotted out, it ought to be possible to formulate a system of timely locust warnings, to neighbouring provinces or countries on the basis of such studies.

Gaps in Our Knowledge of the Indian Protozoa. I.—Ciliophora.

By B. L. Bhatia, D.Sc.

DURING the last four years, while preparing a volume on Ciliophora for the Fauna of British India, I have become aware of various gaps in our knowledge of these Protozoa. Although many more genera and species are now known from this subcontinent than was the case in 1916 when I first directed my attention to this group, there is still a vast and promising field for future workers to cultivate. The Ciliophora are a sub-phylum of the Protozoa, and include forms which live in water, soil, or as parasites of other animals. It is well known that species of fresh-water and soil protozoa are cosmopolitan. The record of Ciliophora known from India, Burma, and Ceylon now includes 274 species belonging to 101 genera. The majority of these are from fresh-water or from the soil. Most of them are the same as found in Europe or America, and there is every likelihood of those described as new, being found in other parts of the world also. This is due to the fact that the conditions of life in pools and ponds are much the same all over the world, and the fresh-water forms can be easily carried from one place to another, especially in the encysted form, by wind and animals. Unlike the fresh-water protozoa, the geographical distribution of parasites usually follows that of their hosts. Some parasites are unable to live in any other host than the one in which they naturally occur and show a host-parasite specificity, though, not unoften, the hosts living in the same habitat may adopt each other's parasites.

The Ciliophora are divided into two classes, *viz.*, CILIATA and SUCTORIA. Following Metcalf, the Opalinid ciliates which do not show a differentiation of the nuclear material into a macronucleus and a micronucleus, have been separated into a subclass and designated as PROTOCILIATA, the rest of the Ciliata which show this nuclear differentiation being called the EUCILIATA.

The Protociliata include a single family *Opalinidæ* which were formerly lumped with other Astomatous ciliates. They are clearly

'an offshoot from the primitive Ciliata before the latter had acquired true binuclearity and the subsequent dimorphism of nuclei'. Metcalf has divided the family into sub-families, PROTOOPALINÆ and OPALININÆ according as the number of nuclei is two or many. The former are not representated in India, and both genera of the latter, *viz.*, *Cepedea* and *Opalina* are known by 8 species of each from various frogs and toads. An examination of Anuran hosts other than those examined already is sure to reveal the existence of many new species. There are many problems about the morphology and physiology of the opalinids which also require further study. The cytoplasmic inclusions, the neuromotor complex as revealed by silver nitrate impregnation and exposure to light, the structure of the nuclei, the nuclear changes during life-history, the causes of the relatively greater abundance of these parasites in the tadpoles than in the adult, are some of the problems well worth further investigation.

The EUCILIATA are divided into 4 orders, *viz.*, HOLOTRICHA, SPIROTRICHA, PERITRICHA and CHONOTRICHA. In the Holotricha the cilia are uniformly distributed over the body in longitudinal rows or limited to particular areas. They comprise the sub-orders GYMNOSTOMATA, TRICHOSTOMATA, HYMENOSTOMATA and ASTOMATA.

All the sub-orders of Holotricha are well represented in India. The Gymnostomata are represented by such well-known genera as *Holophrya*, *Urotricha*, *Prorodon*, *Lacrymaria*, *Enchelis*, *Didinium*, *Coleps*, *Spathidium*, *Bütschlia*, *Litonotus*, *Loxophyllum*, *Dileptus*, *Loxodes*, *Nassula*, *Chilodonella*, etc. *Bütschlia parva* has been recorded from the stomach contents of the ox, and *Chilodonella rhesus* from the intestine of the common Bengal monkey. No representatives have so far been found of the families ACTINOBOLIDÆ, METACYSTIDÆ, DYSTERIDÆ, PYNCNOTHRICHIDÆ and FŒTTINGERIDÆ.

The Trichostomata are classified into 9 families of fresh-water genera, and 4 families of parasitic genera. The fresh-water Trichostomata are represented by species belonging to *Plagiopyla*, *Colpoda*, *Paramecium*, *Drepanomonas* and *Opisthostomum* and the parasitic ones by *Isotricha prostomum* and *Dasytricha ruminantium* from the stomach of ox, and *Charonella ventriculi* from the stomach of the mouse-deer, and three species of *Conchophthirius* which are commensals in the mantle chamber of *Lamellidens*. There are no records of the families SCIADOSTOMIDÆ, SPIROZONIDÆ, TRICHOSPIRIDÆ, CLATHROSTOMIDÆ, MARYNIDÆ and CYATHODINIIDÆ.

The Hymenostomata are represented by species belonging to *Frontonia*, *Sigmostomum*, *Trichoda*, *Glaucoma*, *Colpidium*, *Pseudoglancoma*, *Stegochilum*, *Uronema*, *Ophryoglena*, *Cyclidium*, *Pleuronema*, *Balantiophorus*, *Urocentrum* and *Telotrichidium*. The families PHILASTERIDÆ, LEMBIDÆ, ANCISTRUMIDAE, and HYPOCOMIDÆ are not represented.

The Astomata are divided into 11 families of which the family ANOPLOPHRYIDÆ only is represented by 5 species of *Anoplophrya* and 1 species of *Maupasella*. The family HAPTOPHRYDÆ is doubtfully represented by two species of *Caudalina*, a genus inadequately characterised by Madhava Rao.

The Order SPIROTRICHA is characterised by the peristome possessing an adoral zone of cilia arranged in a left-handed spiral, leading to the cytostome. They comprise the sub-orders HETEROTRICHA, OLIGOTRICHA, ENTODINIOMORPHA, CTENOSTOMATA and HYPOTRICHA.

The Heterotricha are represented by species belonging to the well-known fresh-water genera like *Spirostomum*, *Stentor*, *Folliculina* and *Bursaria*, and equally well-known parasitic genera *Nyctotherus* and *Balantidium*. Nine species of *Nyctotherus* and sixteen species of *Balantidium* have been described from India and Ceylon. The families METOPIDÆ and LICNOPHORIDÆ are however not represented.

The Oligotricha are represented by species of *Halteria*, *Codonella* and *Tintinnopsis*, but the family STROBILIDIIDÆ is not represented.

The Entodiniomorpha including the parasitic genus *Entodinium* and other related genera has been exhaustively studied in a series of three monographs, by Kofoid and Mac Lennan on material collected some years previously at Coonoor and Colombo from the stomach of the ox. The original genera of the Ophryoscolecidæ, *Entodinium*, *Diplodinium* and *Ophryoscolex*, have been split up, and variously shuffled and recombined by various authors. As many as 10 genera and 43 species are recognised by Kofoid and Mac Lennan as occurring in the contents of the stomach of the ox, and species from the stomach of the mouse-deer. The family CYCLOPOSTHIIDÆ is not represented.

The sub-order Ctenostomata recently constituted by Kahl for including the families Epalcidæ, Mylestomidæ and Discomorphidæ, is altogether unrepresented in India, so far as our present knowledge goes. The Hypotricha have not been adequately studied, but still representatives have been recorded of all the principal families. Species of the genera *Peritromoides*, *Urostyla*, *Holosticha*, *Uroleptus*, *Pleurotricha*, *Gastrostyla*, *Gonostomum*, *Oxytricha*, *Balladinopsis*, *Euplotes*, *Aspidisca*, *Aspidiscopsis* have been recorded from different parts of the country.

In the order PERITRICHA are included cone-shaped or bell-shaped organisms, usually attached to various objects by a stalk arising from the dorsal surface. The stalk is frequently retractile like a spiral spring or is divided into a branching system. In the adult organism, the cilia are present only on the ventral surface which forms the vase of the cone. The adoral cilia are arranged in a right-handed spiral. The adoral row of cilia (in some forms two parallel rows), commences at a point on the ventral surface, and follows a course like that of a flat watch-spring till its outer end passes into a cone-shaped depression (or vestibulum), within which lies the cytostome leading to the cytopharynx. The cilia may be continued into the pharynx as such or may fuse to form an undulating membrane. Species of the genera *Scyphidia*, *Vorticella*, *Carchesium*, *Epistylis*, *Cothurina* and *Vaginicola* are known, but representatives of the family Urceolaridæ which includes such ectoparasites as *Urceolaria* and *Trichodina* have not been met with.

The order CHONOTRICHA has been constituted for a small group of forms formerly included in the Peritricha. The peristome is developed as a hyaline, spirally convolute, membranous funnel, one limb of which descends into an oral funnel. The order includes ectoparasites or commensals of crustacea and other aquatic creatures. No one has studied these forms in India so far.

The class SUCTORIA has been almost completely neglected in India. Only a very few species belonging to the genera *Tokophrya*, *Acineta*, *Podophrya* and *Sphærophrya* have been noted. No representative is known of 5 families out of 7 into which the group is divided. Some one should take up the study of this group, in order to make our records of the Protozoan fauna somewhat fuller.

We will now briefly survey some of the major groups of the animal kingdom and indicate from what particular hosts the parasitic ciliates have been studied, and from what others it should be possible to obtain suitable material. There are records of *Balantidium coli* from man, from Calcutta and Lahore but so far as we are aware not from any other part of the country. Cattle, sheep, goats, pigs and horses are our most useful domestic mammals. The rumen (paunch) and reticulum (honeycomb) of the ruminant stomach are œsophageal derivatives and as such contain no glands to secrete either acid or ferments. The contents consist of water and large quantities of saliva mixed with the partially triturated food of the animal, which consists of succulent or dried green plants and grain. The fluid serves as an ideal medium for the growth and multiplication of ciliates, flagellates, amœbæ and bacteria, and there is a Protozoan fauna more or less specific to the ruminants. Buisson (1923), Becker and Talbot (1927) and Dogiel (1927) have published useful work on the intestinal parasites of mammals. Till 1927, according to Dogiel, 65 species and varieties of Ophryoscolecidæ had been found in cattle, 32 in sheep and 19 in goats. As noted above, thanks to the labours of Kofoid and Mac Lennan (1930–33), no less than 43 species belonging to as many as 10 genera are now known from the stomach of the Indian ox (*Bos indicus*) from Coonoor and Colombo.

Jameson has described *Charonella ventriculi* from the cattle, and *Entodinium ovalis* from the mouse-deer from Ceylon. Cooper and Gulati (1926) described *Balantidium coli* var. *bovis* from the cattle. Apart from these interesting records, no one seems to have recorded or described any ciliate parasites from the sheep, goats, pigs or horses. E. Ghosh (1929) described what he regarded as new species of *Balantidium* and of *Chilodonella* from the monkey.

Ciliates are not generally found to occur in the alimentary canals of birds, reptiles or fishes, though one species each of *Balantidium* is known from a bird, a tortoise and a fish from other parts of the world. Frogs and toads are commonly infected with Opalinids, *Balantidium* and *Nyctotherus*. Eleven species of frogs and toads have been studied for their parasites and 17 species of Opalinids, 7 species of *Nyctotherus*, and 10 of *Balantidium* are known from them. Dobell (working in Ceylon in 1910), Ghosh and recently H. Ray in Calcutta, de Mello in Nova Goa, and

Bhatia and Gulati in the Punjab have contributed to our knowledge of these parasites.

Parasites and commensals from Mollusca include a species of *Nyctotherus*, a species of *Balantidium*, 3 species of *Conchopthirius*, and 3 species of *Anoplophrya*. Species of *Nyctotherus* and *Balantidium* are also known from the Cockroach and certain other Arthropods. Species of *Anoplophrya* and *Maupasella* are known from the fresh-water Oligochæte *Aelosoma* and from 2 species of the earthworm *Pheretima*. And lastly, Protozoa are known to parasitize other Protozoa, and a suctorian *Sphærophrya* sp. has been recorded from *Paramecium caudatum*.

Some of the ciliate parasites are very interesting from the morphological point of view. The holotrichan *Ichthyopthirius multifilus* which is parasitic in the skin of fish, the various ciliates which occur in the cæcum of the horse; *Trichodina* which slowly creeps over the external surface of *Hydra* and is also found on the skin of fish; *Spirochona* known to occur on the gills of fresh-water crustacea, and *Licnophora* which is an ectoparasite of various marine animals, should all be looked for by those who have an opportunity to do so, and will very likely be found.

In conclusion, we will say a few words about the regional distribution of the ciliates that have been recorded so far from various parts of India. Following the regional divisions of India as adopted by Stephenson in his volume on Oligochæta in the fauna of British India, the records are as follows:—

1. North-Western Territory (The drainage system of the Indus so far as comprised in the plains of India, including the Punjab, the N.W.F.P., N. Rajputana and Sind). 85 species belonging to 50 genera.
2. Western Himalayan Region (from Hazara to borders of Nepal, including Kashmir). 27 species belonging to 18 genera.
3. North-Eastern Frontier Region (Nepal and eastwards, including Assam). 8 species belonging to 7 genera.
4. Indo-Gangetic Plain (U. P., Bihar and Bengal). 74 species belonging to 39 genera.
5. Burma (including the Andamans and Nicobars). 4 species belonging to 3 genera.
6. Main Peninsular Area (including S. Rajputana and the Central India Agency). 17 species belonging to 12 genera.
7. Southern Region (S. of latitude 15°). 80 species belonging to 31 genera, which record includes 40 species from the stomach of the ox.
8. Western Region (Goa to Cutch, the Ghats to the Sea). 30 species belonging to 26 genera.
9. Ceylon—60 species belonging to 19 genera, which record includes 41 species from the stomach of the ox.

In the present state of our knowledge, no importance can be attached to the presence or absence of any species in the specified regions. Larger number of species as recorded from certain regions is simply due to the fact that these regions have been better worked out. Further work will doubtless show the all-India distribution of most of the species.

Mining and Geological Institute of India.

THE annual general meeting of the Mining and Geological Institute of India was held on 1st February 1935 at Calcutta. In his presidential address W. H. Bates (of Burn and Co.) has surveyed the growth and development of coal trade in Bihar and Orissa for the last 30 years. In his opinion the slump in coal market is not merely due to the world-wide trade depression, but to other local causes; and he considers that the future is not so gloomy as many would like us to believe, especially in view of the possible shortage of oil and other combustible products. The meeting was followed by the Annual Dinner with the Governor of Bengal as the chief guest. Interesting excursions were arranged to several places like Bokaro colliery, *Statesman* offices, etc. The most important work published in the *Transactions* of the year was Dr. Heron's paper on the mineral resources of Rajputana for which the author was rightly awarded the Government of India prize of Rs. 500 and a gold medal.

Insect Transmission of Spike Disease of Sandal (*Santalum album*, Linn.).

By S. Rangaswami,
Madras Forest Department, Denkanikota
and
M. Sreenivasaya,
Department of Biochemistry, Indian Institute of Science, Bangalore.

THE infectious character of Spike Disease having been experimentally demonstrated in a number of ways,[1,2,3,4,5] the next logical step in the investigation was to elucidate the mode of its dissemination under natural conditions. Strong circumstantial evidence, observations of previous investigators and the experience of other related diseases, led to the suspicion that the disease is possibly carried by a specific vector, the nature of which was still obscure.

Platform experiments[6] carried out since 1931 showed that the activity of the vector is confined to certain seasons of the year and that it operates above ground. Further confirmation of this fact was obtained from the natural infections which occurred among the potted sandal plants kept distributed in a heavily spiked area. The caging experiments[6] carried out in the 6-acre regeneration plot at Jawlagiri and later at Nognoor, demonstrated that the vector was effectively screened off by muslin cloth or by wire gauze of 10 to 20 meshes to the inch. The fact that the percentage of disease incidence in a given area was roughly proportional to the intensity of the infliction of scars pointed to the existence of scar-producing agencies which were also possibly responsible for the transmission of the virus. Continued observations showed that 64 per cent. of the scar-bearing plants got spiked while an incidence of only 8 per cent. could be recorded among the control plants which had not received similar injuries.

At this stage of the investigation, the Imperial Forest Entomologist, Dehra Dun, was invited to take up the problem from the entomological point of view. The extensive survey of the insect fauna associated with spiked and healthy areas carried out by Chatterjee,[7] led to the incrimination of a number of groups and individuals as vectors of Spike Disease. A series of carefully designed transmission experiments with these insects was conducted and a "mass infection cage" also was constructed into which were released the insect fauna from heavily spiked areas. Healthy and spiked sandal plants in pots were kept in the cage, so that together with the insect fauna the cage represented a "miniature sandal forest".

The above studies have resulted in the accumulation of mass of useful information and, from an entomologist's point of view, present a unique and very valuable contribution to the forest Entomology of South India. But from the point of view of the problem of insect transmission of spike, the efforts did not lead to any positive results.

A careful study of the experimental technique employed in the above series of studies showed that (1) the insects for the mass infection cage were collected and brought from areas located 50 miles away from Bangalore where the mass infection cage was situated, a circumstance which might have contributed towards the negative results; (2) Dover and Appanna[8,9] state "with the insect fauna we were no more fortunate. In October 1932, we reported a population of twenty thousand and hoped that we should be able to increase it to more than a hundred thousand. But in spite of every effort, the population fluctuated in the vicinity of twenty thousand and it was confined to a very small number of species, though at least two hundred thousand insects representing practically every species taken on sandal in the forest of North Salem, were introduced between June 1932 and March 1933"; (3) The insect fauna released into the mass infection cage mainly consisted of collections made during the day and "en masse" experiments with night fauna were not carried out. Careful and extensive observations had revealed that the scars are inflicted in large numbers during the nights[6] and this fact emphasised the importance of experimenting with the nocturnal insect fauna.

The problem of insect transmission was again taken up in May 1934 and several modifications in the light of past experience were introduced in the experiments. One of the cages was put up right in the midst of a heavily spiked area at Jawlagiri so that the insects could be released into the cage

soon after collection in a "nascent condition". The Denkanikota cage was situated 4 miles away from the centre of insect collections. The insect fauna for the cages were collected from spiked areas—both from sandal and associated host plants—during the night from 9-30 P.M. to 5 A.M. Other experimental details relating to the cages are given in Table I.

TABLE I.

	Denkanikota	Jawlagiri
Dimensions of the cage ..	24′×12′×7′	25′×12′×7′
Mesh of wire gauze ..	20 to an inch.	20 to an inch.
Date of start	7-5-1934	19-8-1934
No. of sandal plants:		
Healthy	42	37
Spiked	24	35
Total number of types introduced into the cage from commencement to date of first spiking ..	190	252
Total number of insects ..	8,421	15,766
Virulence of disease in areas from which insects were collected ..	1	5

At the commencement of the experiments it was observed that the insects did not feed on the spiked plants while on the healthy they could be seen in large numbers. With a view to render the spiked plants more attractive to insect attack, a certain number of them were planted in steel drums ($4' \times 1\frac{3}{4}'$) sunk in the ground. A number of healthy plants also were similarly planted up in the cage. These plants put on a new flush after a few weeks. A fresh batch of 23 healthy and 10 newly spiked plants bearing plenty of spiked foliage were introduced into the cage on 9—12—1934 so that the insects were given every chance to feed on the spiked plants. At the kind suggestion of Mr. M. V. Laurie, Provincial Sylviculturist, Madras (now Imperial Sylviculturist to the Government of India), the cage was partitioned on 9—12—1934 by a collapsible cloth screen. The spiked plants occupied one half of the cage while the healthy plants were placed in the other half. This arrangement enabled a control of the insect fauna in the cage, which could be driven to one or the other half of the cage and induced to feed on spiked or healthy plants as desired.

On 19—1—1935, one of the healthy plants in the cage at Jawlagiri looked highly suspicious after about 5 months and in the course of the next fortnight, the plant exhibited the characteristic symptoms of spike. Material from this plant was tal on 19—2—1935 to Denkanikota and utili for grafting 6 healthy plants, two of wh developed the disease on 28—5—1935, th confirming that the spike symptoms p duced through the agency of insects w transmissible by grafting in just the sa manner as the natural spike tissue is capa of transmitting the disease. The infecti character of the disease produced by inse was thus established, and was theref identical with the natural spike occurrin forests not only with regard to the morp logical symptoms but also with respect its transmissibility of infection thro grafting.

On 8—3—35 two more plants belong to the same series at Jawlagiri manifes the disease. At this stage it was conside desirable to defoliate a certain number the plants still continuing healthy, wit view to force out the masked symptom any. Mr. W. G. Dyson, District Fo Officer, North Salem, kindly suggested t only 50 per cent. of the plants should subjected to this experiment while the should be allowed to remain in the ca 15 from the August and 13 from the cember batches of healthy plants w accordingly removed from the cage 9—3—1935, defoliated and were kept un observation at Denkanikota. These pl were immediately replaced by an e number of healthy plants. About the mi of April 1935, 5 among the defoliated 8 among the plants which continued remain in the cage, all belonging to earlier August series got spiked, brin up the total number of spiked plants t out of the 37 healthy plants introduced the cage at the very commencement of investigation.

It should be made clear that so far t has been no disease incidence among other two batches of healthy plants in duced into the cage in December 1934 March 1935.* These plants are being l under observation. It is remarkable, t has been no incidence among the hea plants in the Denkanikota cage. It wil seen from Table I that the insect fauna l as regards types and individuals is low in the case of the Denkanikota cage the virulence of the Denkanikota area f which the insects were collected for the i

* Since the above was sent to the press. plant in the Denkanikota cage has got spiked

infection cage, is only one-fifth of the virulence characterising the corresponding area at Jawlagiri. In the case of the Denkanikota cage, the insect collections had to be transported over a distance of four miles and were not therefore in as "*nascent*" a condition as those of Jawlagiri. These are possibly the causes for the negative results obtained so far at Denkanikota.

The remarkably high percentage of successful transmissions (43·2%) obtained at Jawlagiri in the mass infection cage, constitute a fundamental advance in the problem of spike disease investigation. The experiments establish that (1) the disease is insect-borne, (2) the insect-vectors occur during the nights, (3) that the vector responsible for disease transmission belongs to one of the 265 types introduced into the cage. On the basis of the frequency of occurrence, seasonal and regional distribution, numerical strength, their morphological characteristics and their reputation as vectors of allied diseases, a large number of groups and individuals have been eliminated, and the scope of our transmission studies with individual species has accordingly been restricted for the present, to three types of *pentatomidæ*, two of *jassidæ* and three of *fulgoridæ*. Transmission studies with these eight insects are now in progress.

Our best thanks are due to Mr. Dyson, D.F.O., North Salem, for his keen interest, constant encouragement and helpful criticisms during the entire course of these investigations, and to Mr. M. V. Laurie, Provincial Sylviculturist, for his many constructive suggestions. Our grateful thanks are also due to Sir C. V. Raman, Kt., F.R.S., N.L., and Dr. V. Subrahmanyan for their kind and continued interest in the investigation.

The Science of Rubber.*

AMONG the natural products which have influenced the progress of modern civilization, rubber occupies a pre-eminent position. The discovery of vulcanisation in the middle of the last century marks the beginning of its technological development while the advent of the pneumatic tyre, the increasing employment of power vehicles and the air craft paved the way for the utilisation of rubber on a gigantic scale. The special and exclusive properties of this raw material, more particularly, its elasticity, high impermeability to gases and liquids, resistance to shock and sound, electrical insulation and a marked resistance to chemical attack, properties which characterise no other single individual material of construction, have been exploited to the fullest advantage by technologists and in this endeavour, they have been assisted by an army of investigators who have contributed to the fundamental aspects of the science of rubber which constitutes the main thesis of the book under review.

The author who was entrusted with the responsible task of solving the problem of war time rubber emergency in Germany had a very enviable opportunity of enriching his experience and this fortunate circumstance has secured for the volume a prestige and authority which none will grudge. The diffcult situation was successfully met by the author and his colleagues whose strenuous efforts in perfecting the process are still being continued. The personal touch of the author is refreshingly perceivable as one goes through the pages of the book.

In this short review it is not possible to do justice by referring to all the excellent aspects of this book, but it is sufficient if attention is called to a few of the most notable features of this volume and indicate the comprehensive and thorough manner in which the subject has been approached. Such a fine production has been made possible through the combined efforts of

* *The Science of Rubber*, edited by Prof. Dipl.-Ing. K. Memmler. Authorised English Translation—Edited by R. F. Dunbrook and V. N. Morris. (Reinhold Publishing Corporation, New York, 1934.) $ 15.00.

several experts who are entitled to speak with authority in their respective fields. The editors of the English translation have maintained the same ideal in view and have selected translators from among the Firestone Research staff, who are best qualified to translate the section of the book apportioned to them. The translators' notes and comments, which appear as footnotes, constitute a valuable feature of the English translation since they amplify, corroborate or supplement the information and thus furnish the reader with an enlarged and extended experience covering the newer developments since the German original was written.

The chapter on the Chemistry of rubber has an added interest since it includes a résumé of the work on the synthesis of rubber conducted in Germany under the stress of war, in the course of which a number of normal and abnormal types of artificial rubber were produced. It is not improbable, that in the near future, most of these will find an appropriate use in industry.

The chapter on vulcanisation, the fundamental process responsible for the phenomenal development of rubber industry, treats with all the latest theories of vulcanisation and accelerator action and indicates the future lines of development. To those interested in the physical properties of rubber, the chapter on the physics of rubber will offer the most interesting and stimulating reading. The colloid chemist in particular will welcome this chapter since it deals with the swelling and solution of rubber and provides him with an array of problems requiring elucidation. It may, however, be mentioned that in the course of reading the book one gets the impression that the pure research that has been conducted on the various aspects of rubber have an intimate bearing on the industrial application. For example, the results on the permeability of rubber to gases in the relation to the quality and treatment of rubber, which has been investigated so thoroughly have been exploited in the development of aeronautics. The optical and electrical properties of rubber and its solution, which are of great technical importance, have also been treated.

For the first time, the physical methods of testing rubber have been brought together in a single chapter and this constitutes a very valuable contribution from the point of view of a technologist since most of these methods suggest possibilities of application in other fields of technology, more particularly in the fields of resins and plastics.

The chapter on the microscopy of technical vulcanizates, describes methods by which rubber can be investigated by reflected and transmitted lights as also by the dark field illumination, and these observations are illustrated by a series of faithfully and beautifully reproduced colour plates.

The fact that the Firestone Tyre and Rubber Company have permitted the members of their technical staff to engage themselves in this work of translation not only speaks of their progressive ideas but also of the high esteem in which Memmler's book is held by rubber technologists. This treatise on the science of rubber will be gratefully welcomed not only by those interested in the science and technology of rubber, but also by those interested in allied fields. It is hoped that the enterprising publishers who deserve to be congratulated in publishing this volume, will soon bring out an equally authoritative and comprehensive companion volume on the technology of rubber.

M. S.

Archæological Discoveries at Narunjadharao.

CONSIDERABLE importance is attached to the discoveries of Mr. U. T. Thakur, a young Sindhi Scholar at Narunjadharao, in Khairpur State. Experimental excavations have yielded interesting relics such as shells, bangles, images of Buddha, gold and copper, skeletons and pottery. It is anticipated that these discoveries will throw considerable light on the Mohenjadharao civilisation and the site will be revealed to the world as a centre of pre-Aryan culture. It is reported that Professor Ghory of Bombay has supported the claims of the discoverer. The State authorities have reserved the sites for further excavation and further work will be started in the coming winter.

Aquarium Fishes.*

IT is hardly realised that the ponds and ditches of India are full of small, brilliantly coloured fishes, some of which are greatly prized by aquarists in America and Europe. Millions of these fishes are trapped or netted every day for food purposes without the least idea that if a trade in these very fishes is properly organized, it can be a source of considerable income to the fishermen. An Englishman, whose wife and children were greatly interested at home in aquarium fishes, once enquired from the writer whether there were any aquarium fishes in India so that his family could spend a few happy hours with them every day during their stay in Calcutta. He was directed to collect fishes from any pond with a growth of aquatic plants and to his great surprise he obtained in one morning several specimens of *Brachydanio rerio*, *Esomus danricus*, *Barbus ticto*, *Barbus conchonius*, *Panchax panchax*, *Colisa lalia*, *Colisa fasciata*, *Nandus nandus*, *Badis badis*, *Ambassis lala*, etc., etc. The wealth of material is simply staggering and though in India fishes can be kept in aquaria with considerable ease, there are several points on which an aquarist needs instructions and proper guidance. Several books have been written on "Aquarium Fishes" to meet this need, but the recent book of William T. Innes of Philadelphia entitled "Exotic Aquarium Fishes" is the best work of general reference that has been published so far. Mr. Innes besides being the editor of a very popular journal "The Aquarium" is the author of "The Modern Aquarium" and "Goldfish Varieties and Tropical Aquarium Fishes". As an editor of a popular aquarium magazine, Mr. Innes is flooded with enquiries of all sorts and this has afforded him an opportunity to know what kind of an aquarium book general readers need and want.

The greatest need of an aquarist is to know how he can keep his aquarium and fish healthy and to meet this demand the author has devoted a great deal of space to "Primary Principles" dealing with oxygen, light, temperature and food. Attention is also directed to fishfoods, enemies and diseases of aquarium fishes, general management of aquarium and plants and planting. The classification of the aquarium fishes is in conformity with the rules of zoological nomenclature and in this connection the author had the benefit of the advice of Dr. George S. Myers, a great authority on the taxonomy of fishes. Each fish is properly illustrated and a vivid description of its habitat and habits is given. The author has given detailed information regarding the pronunciation of scientific names, the spawning of the egg-layers, the breeding of the live-bearers, the breeding of the Bubble-nest Builders, the hybrids and hybridising, the wholesale breeding of fishes and the sex changes in fishes. Useful hints are included about the collecting and transporting of aquarium fishes. An index of fishes and a cross index of general subject render the information contained in the book easily accessible. A special feature of the book is the inclusion of maps. There are seven small maps showing the world distribution of the 7 most important families of aquarium fishes. A world map is also given and under each species is included a key reference to the places on this map showing points from which the species has been taken. In short, the book is a compendium of much useful information concerning aquarium fishes and no pains have been spared to make it most up-to-date and authoritative. The author is to be congratulated on this production and the publishers, Messrs. Innes Publishing Company, have really brought out a work of art. The paper, the get-up, the printing, the binding, etc., are all that could be desired for the very moderate price of 5 dollars (postpaid).

Letters to the Editor.

CONTENTS.

Note on Transport Phenomena and Quantum Mechanics.

IN a recent paper we have studied the transport phenomena by modifying Maxwell's method in the light of the new Statistical methods. The dynamics of Collision was studied by a method due to Perisco. In recent years Wave-mechanical collisional methods have been developed by several authors and Massey and Mohr have shown how collisional area obtained by the above methods can be used for studying transport phenomena.

In the present investigation we have incorporated the Wave-mechanical method for studying scattering of electrons by a positive nucleus and thus calculated the value of the constants A_1, A_2 represented by the expressions

$$A_1 = 2\pi\int I(\theta)\sin^2\theta/2.\sin\theta\, d\,\theta$$

$$A_2 = 2\pi\int I(\theta)\sin^3\theta\, d\,\theta$$

where $I(\theta)$ is the intensity of scattering, θ is the angle of scattering.

Taking Wentzel's expression

$$I(\theta) = \left(\frac{Z\epsilon^2}{2mv^2}\right)^2\int\frac{d\theta}{(\sin^2\theta/2+b)^2}$$

where Z is the atomic number, ϵ =electronic charge, m the mass and v the velocity of the electron, $b = \frac{1}{4k^2R^2}$, $k = \frac{2\pi mv}{h}$, R = distance between the two particles.

For completely ionised stellar matter $r=\frac{1}{2}\left(\frac{Am_H}{\rho}\right)^{1/3}$ where A is the average mol. wt., m_H =wt. of the H atom, ρ the density of stellar matter.

We thus have

$$A_1 = 4\pi\left(\frac{Z\epsilon^2}{2mv^2}\right)^2\left[\log\frac{1+b}{b} - \frac{1}{1+b}\right]$$

$$A_2 = 16\pi\left(\frac{Z\epsilon^2}{2mv^2}\right)^2\left[(1+2b)\log\frac{1+b}{b} - 2\right]$$

A_1 and A_2 may be computed for different cases and their values introduced into our previous formula, would lead to the evaluation of viscosity k, conductivity h, self-diffusion D and diffusion between two different gases D_{12}.

In the following tables are given values for some well-known giant and dwarf stars.

The first three stars are assumed to contain completely ionised iron while the last two completely ionised Ca-atom. It has already been pointed out that Kothari's Model-Dwarf should be treated relativistically. Here however non-relativistic values have been

Stars	Density	Temp.	Viscosity k in e.s.u.	Conductivity in gm./cal.	Self-Diffusion D	Diffusion D_{12}
Model-Giant (Chapman) ..	0·1	7×10^6	$9\cdot986\times10^{-3}$	13·3	$1\cdot998\times10^3$	14·93
Capella	0·1234	$9\cdot08\times10^6$	·02	2·70	$6\cdot6\times10^3$	10·3
Model-Dwarf (Kothari) ..	$1\cdot36\times10^6$	$1\cdot37\times10^7$	$6\cdot904\times10^2$	$1\cdot685\times10^5$	6·048	
ϵ_2 Eridani	$9\cdot8\times10^4$	10^8	3·719	$3\cdot242\times10^4$	1·350	
Sirius B	5×10^4	10^9	1·216	$1\cdot658\times10^5$	·688	
,, ,, ...	,,	10^8	1·216	$1\cdot658\times10^4$	·688	
,, ,, ...	,,	$1\cdot37\times10^7$	1·216	$2\cdot271\times10^3$	·688	

calculated for comparison. It is noticed that viscosity and diffusion are effected by density alone increasing with increasing density while conductivity is a function of temperature as well.

For the relativistic case $I(\theta)$ involves a factor $(1-v^2/c^2)$ and hence is greatly diminished while for $v\sim c$, $I(\theta)\sim0$ and hence, k, $\mathfrak{L}$ and D have zero values.

Note on Surface Tension and Its Variation with Temperature.

IN connection with a recent note[1] of Sibaiya "On the ratio of temperature co-efficients of surface tension and density" it may be pointed out that Cantor[2] who followed the same method as Sibaiya obtained the value of the ratio 2·33 instead of 2.

The nature of the cohesive forces has been studied in detail in recent years and the following relationship between Van der Waals force and the surface tension has been established.[3]

$$\text{Van der Waals Constant } a = 2\pi\int_0^R \psi(z)dz$$

$$\text{Surface Tension } \gamma = \pi\rho^2\int_0^R z\psi(z)dz$$

Lately London[4] has given a quantum-mechanical expression of Van der Waals force. According to him the interaction energy between two similar molecules is given by

$$\epsilon = -\tfrac{3}{4}\cdot\frac{\alpha^2 J}{R^6} = \frac{k}{R^6}$$

where J is the ionisation potential, α the polarisability and R the distance between the molecules. This corresponds to the potential $\psi(z)$ of Laplace. By introducing the above expression for $\psi(z)$ we have

$$\gamma = \frac{\pi k\rho^2}{4d^2} \quad .. \quad .. \quad .. \quad .. \quad (1)$$

Expression (1) was derived by Gyemant[5] as well by considering the surface energy originating from electric dipole.

By differentiating (1) with respect to T

$$\frac{d\gamma}{dT} = \frac{2\pi k\rho}{4d^2}\frac{d\rho}{dT} - \frac{\pi k\rho^2}{4}\cdot\frac{2}{d^3}\cdot\frac{dd}{dT} + \frac{\pi\rho^2}{4d^2}\cdot\frac{dk}{dT}$$

or,

$$\frac{1}{\gamma}\cdot\frac{d\gamma}{dT} = \frac{2}{\rho}\frac{d\rho}{dT} - \frac{2}{d}\cdot\frac{dd}{dT} + \frac{1}{k}\cdot\frac{dk}{dT} \quad .. \quad (2)$$

If β be the co-efficient of cubical expansion = thrice the co-efficient of linear expansion,

$$\frac{1}{\gamma}\cdot\frac{d\gamma}{dT} = -2\cdot66\,\beta + \frac{1}{k}\frac{dk}{dT} \quad .. \quad .. \quad (3)$$

Now in order to study the effect of temperature on k we must remember that

$$k = -\tfrac{3}{4}\,h\nu_0\alpha^2, \text{ where } \alpha = \alpha_0 + \frac{\mu^2}{3kT},$$

$$\nu_0 = \frac{c}{\sqrt{m\alpha}} \text{ and } h\nu_0 = J.$$

If there is no permanent dipole moment $(\mu=0)$ α and ν_0 and so k are independent of temperature. On the other hand if $\alpha_0 \ll \frac{\mu^2}{3kT}$, the expression for surface tension reduces to the formula similar to Gyemant's and

$$k = -\tfrac{3}{4}\cdot\frac{hc}{\sqrt{m}}\cdot\frac{\mu^3}{(3k)^{3/2}}\cdot\frac{1}{T^{3/2}}, \text{ and}$$

$$\frac{1}{k}\cdot\frac{dk}{dT} = -\frac{3}{2T}.$$

It should however be noted that London's

formula is to be modified for complex substances such as liquids and solids. That solids have surface tension has now been pretty well established. In the case of adsorption of gases the adsorbed molecules are held to the surface of the adsorbent by cohesive forces. Now it has been observed that the same adsorbent may adsorb varying amounts of adsorbent, when subjected to different treatment. Activation of charcoal is a familiar instance. It is supposed that the specific surface increases with activation. Now if the total surface energy be the same then the increase of surface would be associated with the decrease of surface energy per unit surface and this would lead to a corresponding decrease of adsorption per unit area. This is not actually the case. The total adsorption increases and if the adsorption per unit surface is the same, this would mean constancy of surface energy. Thus for solids it is preferable to study surface tension by considering the surface density of molecules distributed over surface, the surface layer being one or several molecules thick and this ρ in the expression (1) should be replaced by $1/\Omega$, Ω being the available surface.

Colloidalisation and Cold-Working of Metals.

THE subject of the magnetic properties of non-ferromagnetic metals has attained much interest recently in view of the work of Pauli, Sommerfeld and others on the theory of the metallic state.[1] The simplest picture of the metal that will suit our purpose consists of a lattice of metallic ions, the remaining electrons in each atom being associated with two or more nuclei and considered as free or partly bound in accordance with their relative energy values. The susceptibility of the metal is to be considered as the sum of the susceptibilities of the ions and of the remaining or valency electrons of the individual atoms. The first part is a constant while the second is greatly influenced by the physical conditions. The large deviations in the values for metals obtained by different workers is to be attributed to the fact that their metals were not in the same state and hence the susceptibility of the valency electrons should have been greatly different.

The valency electrons may have large orbits as contemplated by Ehrenfest[2] for graphite and by Raman[3] for bismuth. Or they may be attached loosely to two close atoms, being considered as free or partly bound. On colloidalisation, the first type would give rise to decreased diamagnetism due to the fact that large orbits could not be possible at the surface. This conclusion has been experimentally established for graphite[4] and bismuth,[5] and in fact, in the case of graphite, Krishnan and Ganguli[6] have determined the direction of largest variation as the one parallel to the hexagonal axis.

In the case of good conductors, the state of affairs is different. The electrons on the surface of the atoms may be considered as free, the number of such electrons being of the same order as the number of atoms in the metal. Considered as free, the electrons possess the Pauli paramagnetism and if regarded as confined to a series of energy bands, they contribute a diamagnetic component.

Honda and Shimizu[7] have shown that cold-working in the case of copper and silver gives rise to increased diamagnetism. They have quantitatively accounted for this result as being due (1) to the decrease in paramagnetic component due to the diminution of free electrons caused by the expansion on cold-working (for which there is ample evidence from X-ray data[8]) and (2) to the increase in the diamagnetic component due to the increased number of bound electrons. They explain that the lattice constant is a little greater in the surface layer than in the interior, the normal value for the metal being reached at some hundred layers below the surface. Thus colloidalisation should be accompanied by increased diamagnetism quite similar to what is obtained in the case of cold-working.

Attention has been drawn to this similarity in the case of tin by Honda and Shimizu.[9]

I have recently verified this result in the case of copper. Colloidalisation by condensed electric discharge in an inert organic liquid in the absence of air, gives rise to an increase in the diamagnetic susceptibility. The question of impurities affecting the measurements does not arise here since all the ordinary compounds of copper are paramagnetic or less diamagnetic than the metal. Here then we have a new kind of increased diamagnetism on colloidalisation.

I take this opportunity of drawing attention to a recent letter in these pages by Verma and Gupta.[10] They have once again drawn attention to the old question of impurities modifying the results. I shall content myself here by just mentioning that they have not been fair to the literature on the subject. It is enough if mention is made of the fact that the fundamental experiment which settled the decrease of diamagnetism on colloidalisation in the case of bismuth was the observed recovery of the value of 1·32 (the value for the mass metal) on melting and cooling of a sample of the colloidal bismuth. In the rather profuse literature they have cited, they have omitted to quote the one paper[5] which outlined this conclusive experiment.

Full details will appear shortly elsewhere.

A Note on the Bond Energies from Raman Frequencies and Thermochemical Data.

GANESHAN[1] has measured the Raman frequencies corresponding to the Se=O and S=O bonds. From the data collected by him, it is clear that there is a general agreement between the bond energy values got from light scattering and those obtained from thermochemical data. A closer examination, however, reveals an appreciable discrepancy between the values of the heats of dissociation calculated from the Raman frequencies and those obtained from the thermochemical data relating to the *ions*. The present note deals with the significance of this disagreement.

It is to be noted that the heats of formation of the ions SeO_4^{--}, SeO_3^{--}, SO_4^{--} and SO_3^{--}, as given in the *International Critical Tables* (**5**, p. 178) are only relative in so far as they are calculated by arbitrarily assuming that the heat of formation of $H^+_{(aq)}$ from H_2 (in its standard state) is zero. In view of this fact, the values calculated by Ganeshan are to be interpreted as follows:

$$H_{2(\text{gas, 1 atmos.})} + Se_{(\text{solid})} + 2O_{2\,(\text{gas, 1 atmos.})} + aq \rightarrow 2H^+_{(aq)} + SeO_4^{--}{}_{(aq)} + 147 \text{ K. cals.} \quad (1)$$

$$4O \rightarrow 2O_{2(\text{gas, 1 atmos.})} + 232 \text{ K. cals.} \quad \cdot\cdot \quad (2)$$

Combining equations (1) and (2), one gets

$$H_{2(\text{gas, 1 atmos.})} + Se_{(\text{solid})} + 4\,O + aq \rightarrow 2H^+_{(aq)} + SeO_4^{--}{}_{(aq)} + 379 \text{ K. cals.} \quad (3)$$

Since the heat of formation of $H^+_{(aq)}$ is not known, that of $SeO_4^{--}{}_{(aq)}$ cannot be calculated. Furthermore, the heat of reaction as given in equation (3) does not give the absolute value of the heat of formation of SeO_4^{--}, so that one cannot expect it to agree with the value got from the Raman frequency of the Se=O bond.

The question then arises as to whether the Raman frequency gives an idea of the absolute heat of formation of SeO_4^{--} *ion* in solution. If this is true, one can put

$$Se_{(\text{solid})} + 4\,O + aq + 2\ominus \rightarrow SeO_4^{--}{}_{(aq)} + 344 \text{ K. cals.} \quad \cdot\cdot \quad (4)$$

Combining equations (3) and (4), one gets,

$$H_{2(\text{gas, 1 atmos.})} + aq \rightarrow 2\,H^+_{(aq)} + 2\ominus + 35 \text{ K. cals.} \quad \cdot\cdot \quad (5)$$

It is also possible to calculate the heat of reaction in equation (5) by knowing the Raman frequencies of SeO_3^{--}, SO_4^{--} and SO_3^{--}. Table I gives the values so obtained.

The large variance in the values for the heat of formation of $H^+_{(aq)}$ indicates that the Raman frequencies enable one to calculate only the heat of formation of *molecules* but not of *ions* in solution.

TABLE I.

Ion whose data are employed	Heat of formation of $H^+_{(aq)}$
SeO_4^{--}	35 K. cals.
SeO_3^{--}	39 ,,
SO_4^{--}	72 ,,
SO_3^{--}	42 ,,

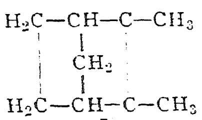
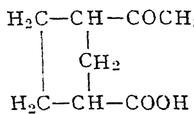
Bicyclo (1 : 2 : 3)-*octane*-2 : 4-*dione*.

ALTHOUGH the constitution assigned to santene (I) by Semmler has been confirmed by direct synthesis,[1] the synthesis of the ketonic acids (II) isolated by Semmler and Bartelt[2] as an oxidation product of santene has not been achieved so far. The acid (II) has now been synthesised starting from *cis-cyclo*pentane-1 : 3-dicarboxylic acid and the investigation continued with a view to synthesising compounds of the type of homo*nor*camphor (VIII).

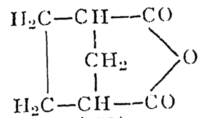


(I)

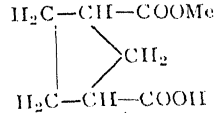


(II)

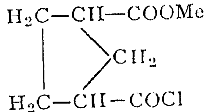
*Cis-cyclo*pentane—1 : 3-dicarboxylic anhydride (III)[3] furnishes the mono methyl ester (IV) in the usual way (b.p. 156°/4 mm.). The mono ester mono-acid chloride (V) prepared from (IV) by treatment with thionylchloride is a colourless mobile liquid (b.p. 109°/3 mm.) which gives by Blaise reaction with zinc methyl iodide the ketonic ester (VI) (b.p. 100°/2 mm. purified through semicarbazone, m.p. 139°). The ketonic acid (II) prepared from (VI) by hydrolysis boils when pure sharply at 155°/5 mm., and not within a range of 30°, *viz.*, 175–205°/10 mm. as given by Semmler and Bartelt.[2] They did not analyse this compound and it seems quite probable that their compound was not pure. The semicarbazone melts at 169° (Semmler and Bartelt 168°).



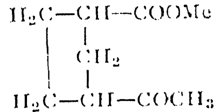
(III)



(IV)



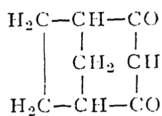
(V)



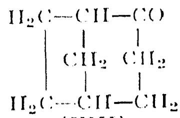
(VI)

The ketonic ester (VI) on treatment with sodium methoxide in alcoholic solution furnishes a product from which the ketonic acid (II) and a solid m.p. 123°·5 could be isolated by distillation, and subsequent treatment with petrol (obtained in poor yield). The solid gives a semicarbazone m.p. 224°, a brownish colouration with ferric chloride and evolves hydrobromic acid with bromine in chloroform solution and seems in all probability to be the bicyclic diketone (VII).

Experiments are in progress for obtaining the solid m.p. 123°·5 in workable quantities, with a view to confirming its structure as



(VII)



(VIII)

also to partially reduce it to the monoketone (VIII)—the next higher homologue of *nor*-camphor.

Full details will be published shortly elsewhere.

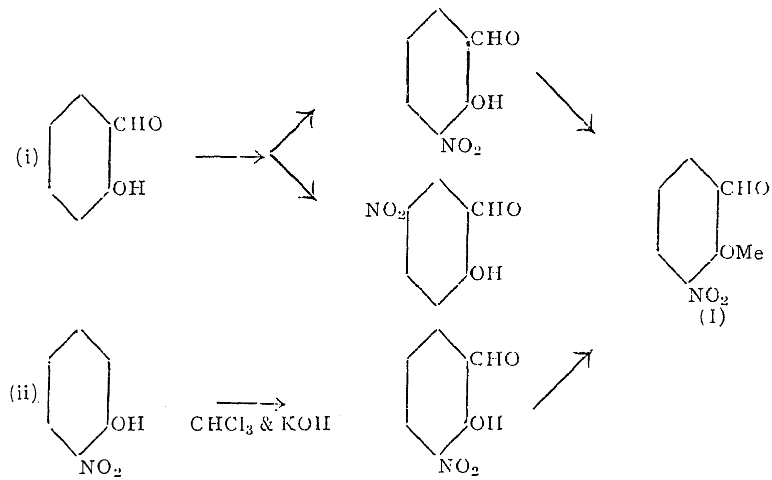
A Preliminary Note on the Nitration of Methyl-Ether of Salicylaldehyde.

DURING the course of synthetical experiments in the group of alkaloids, we required Iso-Orthovanillin as a starting substance and it was thought that the latter might be obtained from 3-Nitromethyl-salicylaldehyde

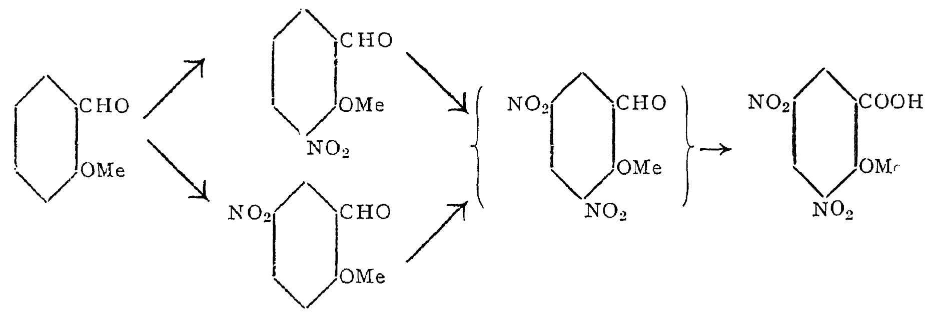
(I). 3-Nitromethyl-salicylaldehyde has so far been obtained only from 3-Nitrosalicylaldehyde which in its turn has been synthesised by two entirely different methods indicated below, one due to Miller,[1] and the other due to Sen and Ray[2] :—



Both the methods of preparation of 3-Nitrosalicylaldehyde are very tedious, and the method of Sen and Ray gives exceedingly poor yield. Further 3-Nitrosalicylaldehyde cannot be readily methylated by dimethylsulphate and alkali, and special methods (*viz.*, diazomethane or silver salt) have to be used for this purpose.[3] It was therefore thought desirable to explore methods of direct synthesis of 3-Nitromethylsalicylaldehyde.

Methyl ether of salicylaldehyde was first nitrated by Voswinckel,[4] and then by Schnell.[5] The latter author showed that if nitration were carried out with fuming nitric acid below 15°, then only 5-Nitrosalicylaldehyde-methylether is formed. These results were confirmed by Hodgson and Smith in 1930.[6] These results did not appear to the present author to be quite correct as it was thought that the 3-Nitro-compound should also have been formed just as in the case of the nitration of salicylaldehyde itself. A repetition of Schnell's experiment and careful working up of the nitration product showed that 3-Nitromethylsalicylaldehyde is actually formed in a yield of about 20%. The separation is best effected in the following manner. The crude solid nitration product is first carefully extracted with *cold* sodium carbonate solution, which extracts the dinitrosalicylic acid which is formed in small quantities at the same time. The dry residue is crystallised from benzene when 5-Nitromethylsalicylaldehyde m.p. 89° separates first. From the benzene mother-liquors petroleum ether (b.p. 30°–50°) precipitates a mixture m.p. 40°–50°. This is converted into the *p*-toluidide, and the *p*-toluidide subjected to a series of careful fractional crystallisations from alcohol. The *p*-toluidide of the 5-Nitro-compound which is only sparingly soluble in alcohol separates first in needles m.p. 165°, and from the mother-liquors the *p*-toluidide of the 3-Nitro-compound is then obtained in prismatic plates m.p. 92° (identical with the *p*-toluidide obtained from an authentic specimen of 3-Nitrosalicylaldehyde). The latter on hydrolysis gives 3-Nitromethylsalicylaldehyde m.p. 102°, identical in all respects with an authentic specimen of 3-Nitromethylsalicylaldehyde prepared by the older method—the mixed melting point being not lowered.

The results of these experiments may be briefly summarised thus :—



The detailed account of these experiments, and synthesis of Iso-ortho-Vanillin would be published elsewhere and are reserved for a future communication.

Ascorbic Acid Content of Some Plant Fluids.

IN an investigation on the occurrence of rich sources of ascorbic acid in Indian food materials, the water inside the coconut fruit and the juice sapped from coconut tree in a similar manner as in the case of date palms, as also juice drawn from the spadix of palmyra palm were examined. These juices and the coconut water are drunk as such and also as toddy (somewhat fermented juice). The following tabular statement gives a synopsis of a few observations:—

TABLE I.
Green Coconut (No Kernel yet formed).

	Volume of Water in one fruit	Natural pH	Volume of Standardised dye= mg. Ascorbic Acid for 10 c.c. Juice at pH·3
Sample 1 ..	340 c.c.	5·0	0·15 c.c. dye
Sample 2 ..	332 c.c.	4·8	0·12 c.c. dye
Sample 3 ..	320 c.c.	4·8	0·12 c.c. dye

TABLE II.
Green Coconut with Soft Kernel.

Sample 1 ..	450 c.c.	4·9	0·15 c.c. dye
Sample 2 ..	225 c.c.	5·0	0·29 c.c. dye

TABLE III.
Ripe and Dry Coconut with Hard Kernel.

Sample 1 ..	40 c.c.	5·1	0·00 c.c. dye
Sample 2 ..	150 c.c.	5·4	0·00 c.c. dye

	Volume of Water in one fruit	Natural pH	Volume of Standardised dye= mg. Ascorbic Acid for 10 c.c. Juice at pH·3

TABLE IV.
Juice from Date Palm Tree.

Sample 1 ..		4·6	1·08 c.c. dye
Sample 2 ..		4·5	1·10 c.c. dye

TABLE V.
Coconut Tree Juice.

Sample 1 ..		4·7	1·60 c.c. dye
Sample 2 ..		4·5	2·00 c.c. dye
Sample 3 ..		4·2	3·00 c.c. dye
Sample 4 ..		4·5	3·00 c.c. dye

TABLE VI.
Palmyra Palm Juice from Spadix.

Sample 1 ..		4·8	1·90 c.c. dye
Sample 2 ..		4·4	1·00 c.c. dye

Expressed juice from ripe pine apple fruits from local markets were also examined and some of the results are here given for comparison.

TABLE VII.
Pine Apple Juice.

	Fruit Material	Juice Expressed	Natural pH	Titre for 10 c.c. Juice
Sample 1	100 g.	70 c.c.	4·0	0·20 c.c.
Sample 2	100 g.	70 c.c.	4·2	1·30 c.c.
Sample 3	100 g.	65 c.c.	4·2	1·00 c.c.

In the cases of the pine apple juice it was found that only a fraction of the total ascorbic acid is pressed out. Extraction by trichloro-acetic acid gave very much higher values—4 or 5 times as much.

As indicated above in the tables 1 c.c. of the 2 : 6 dichlorophenol-indophenol dye was standardised equivalent to 1 mg. ascorbic acid.

In the above estimations it may be noted that the volume of the dye required did not vary even after suitable treatment of the juices by mercuric acetate, H_2S, etc.

It will be seen from the above that coconut water loses ascorbic acid as the fruit ripens

and gets dry. Of all the plant saps examined coconut tree juice has been found to be the richest source of ascorbic acid. The quantity of juice yielded by date palm and palmyra palm trees daily is also quite considerable, so that the ascorbic acid excreted is very high. It was noted that the ascorbic acid content did not suffer any change even after spontaneous fermentation for 24 hours.

Further details and the transference of ascorbic acid from the water into the kernel according to age of the fruit etc. will appear in the *Transactions of the Bose Research Institute*.

The Cultivation of *Artemisia*.

FOR some time past attention has been directed to the cultivation of *Artemisia brevifolia* from seeds obtained from the santonine yielding varieties of the Kurram Valley (N.W.F.P.) and the Kashmir, with a view to raising the santonine content of the wild species. It has been reported, elsewhere,* that the Kurram *Artemisia* grows well in Dehra Dun, as a garden plant, but the plants divide themselves in two sub-forms designated as the x-form and the y-form; the only distinction between the two being that one produced the flower heads early in June and the other did not show any flower heads till late in the year. It was consequently suggested that the one flowering late was the original form and the earlier flowering variety was the acclimatised form. Similar growth has been noted in the case of the Kashmir *Artemisias*. During the first year some of the plants started flowering early (May-June) and the others did not flower till November suggesting again the original and the acclimatised form. Both the Kashmir and the Kurram Valley *Artemisias* have now well established themselves and the later observations have revealed the fact that instead of the two forms stated above there is only one, but that it produces flower heads twice a year and consequently has two periods of maximum santonine content, namely, June and December. The hope that the santonine content would rise on cultivation has, however, not yet been realised. The above observations are rather interesting from the point of view of cultivation of the drug and are therefore reported. The table given below gives the santonine content of the samples collected from the minor forest products gardens of the Forest Research Institute.

Time of collection weeks		Santonine percentage	Remarks
4, August	1933	0·60	Young leaves only
4, October	1933	0·79	Buds only
1, December	1933	0·91	Leaves and buds
1, January	1934	0·78	,, ,,
1, February	1934	0·12	,, ,,
1, March	1934	0·66	Fresh leaves
1, April	1934	0·80	Luxuriant growth but no buds
1, May	1934	0·84	,, ,,
1, June	1934	0·85	Buds making appearance
3, June	1934	0·98	Buds
1, July	1934	0·52	Early rains dropped the buds
1, August	1934	0·22	,, ,,
4, August	1934	0·62	Fresh young leaves

Czapek's Synthetic Medium.

CZAPEK'S formula for synthetic medium has been in use for over thirty years for culturing fungi. It consists of nitrate, phosphate, sulphate and chloride in addition to the organic principle, which is sucrose. It has, from time to time, been modified to suit the requirements of individual workers. In 1910 Dox modified this formula to present in a nearly neutral solution unaffected by sterilisation the elements necessary for the fungous growth. The original formula contained acid potassium phosphate (KH_2PO_4), while in this modified one Dipotassium hydrogen phosphate (K_2HPO_4) was used to obtain a neutral solution. Previous to this Dox[2] had used the original formula in a modified form with different proportions of the constituent salts. Currie[3] in 1917 used acid potassium phosphate for *Aspergillus niger*.

During the preparation of Czapek's solution as modified by Dox it was frequently noticed that the addition of ferrous sulphate solution gave traces of milkiness, while the

latter formula, according to which acid potassium phosphate was used, gave a clear solution as reported by Thom.[1]

On being heated to a high temperature in the autoclave, the milky product settles down as a bulky precipitate. The precipitate consists of magnesium phosphate with traces of iron. Thom[1] and later, Thom and Currie[4] have also noticed traces of precipitated magnesium phosphate.

In this note an attempt is made to study the chemical reactions of the constituent inorganic salts and the effect of the high autoclave temperature on the reactions. One per cent. solutions of pure salts in distilled water were used.

Magnesium sulphate and di-potassium hydrogen phosphate react only at the boiling temperature, when magnesium precipitates as the phosphate. The presence of sodium nitrate alone or with potassium chloride has no effect on the reaction. But the presence of ferrous sulphate even in traces has its part in the reaction and iron is also precipitated along with magnesium even at the ordinary temperature as well as at the boiling or autoclave temperature.

Magnesium sulphate and sodium nitrate or potassium chloride in the absence of di-potassium phosphate do not give a precipitate either at the ordinary temperature or on boiling, even when potassium chloride is present. But when ferrous sulphate is present, slight milkiness is produced, which, on boiling, disappears. When subjected to the high temperature in the autoclave ferric oxide is precipitated.

Ferrous sulphate reacts with di-potassium phosphate at the ordinary temperature even in the absence of magnesium sulphate or potassium chloride and gives a precipitate of ferrous phosphate.

Sodium nitrate and ferrous sulphate do not give any precipitate but in presence of potassium chloride some milkiness is produced which disappears on boiling.

Even in aqueous solution ferrous sulphate changes at the temperature of the autoclave into ferric oxide.

Sterility of Crop-Plants and a Study of Their Root-System.

STERILITY in crop-plants is fairly well known indeed; it, therefore, does not need any special elucidation. Suffice it to mention that the phenomenon is attended with abundant vegetative growth and as a consequence the sterile plant or branch, in habit looks bushy (Figs. 3 and 4). Studies based on *Trifolium alexanderinum* L. (berseem),[1]

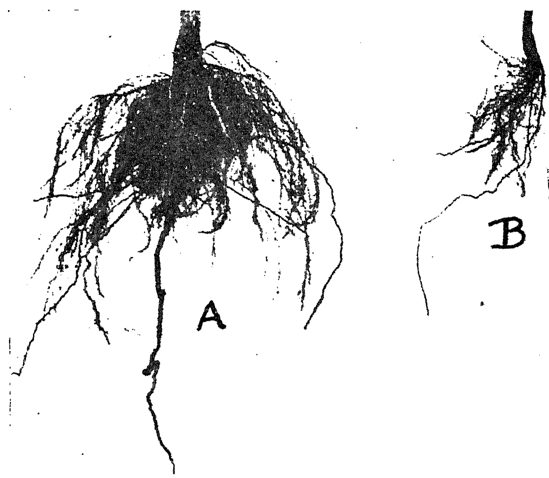

Fig. 1.

Sesamum indicum Linn. A—root-system of a healthy plant; B—root-system of a sterile plant. × 1/6.

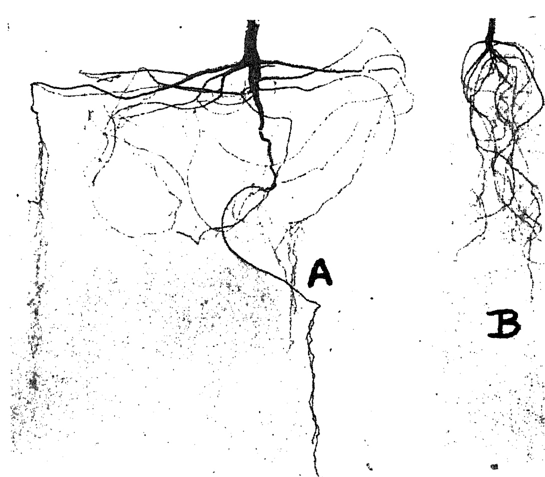

Fig. 2.

Cajanus indicus Spreng. A—root-system of a healthy plant; B—root-system of a sterile plant. × 1/20.

Crotalaria juncea L. (sunn-hemp), *Cajanus indicus* Spreng. (rahar), *Sesamum indicum* L. (til) and *Cicer arietinum* L. (gram), have

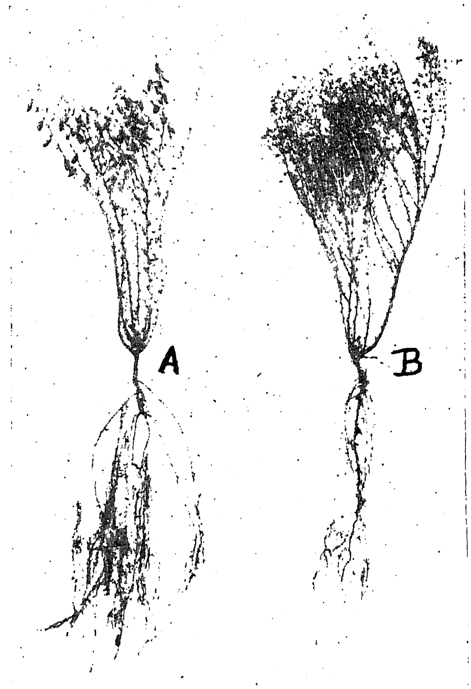

Fig. 3.

Cicer arietinum Linn. A—a normal plant with its strongly developed root-system; B—a sterile plant with its meagrely developed root-system. Note the bushy habit of the plant B. × 1/12.

shown beyond doubt that sterility observed in these is due largely to sepaloidy of petals and transformation of essential organs into very much branched shoots and leaves.[2] An extreme case, however, is found in *Cajanus indicus* Spreng. (rahar) where matters are not so clear as stated above.

A careful study of these sterile plants has evoked some interest. It has been noticed as a result of a number of root-washings that the display of root in sterile specimens is comparatively very poor, the tap- and secondary-roots being very weak and inadequate (Figs. 1-3). In addition, the number and size of root-nodules are also much smaller in the case of leguminous specimens. Whereas, in normal healthy plants, the development of the roots and nodules is fairly strong and profuse (Figs. 1-3).

This correlative study of the sterile plants and their root-system gave rise to the suspicion whether the phenomenon was not purely of a physiological nature rather than genetical as known in other crops, *e.g.*, rice.[3] At a time when this tentative conclusion was arrived at, all the crops had been harvested except *rahar* in which a number of sterile plants were available. Experiments could, therefore, be started only on one crop.

Sets of sterile *rahar* plants were treated as follows and controls were maintained as usual:

(*a*) Plants were irrigated at regular intervals with a very weak solution of pyro-phosphate of soda with a trace of potassium chloride.

(*b*) Plants were irrigated at regular intervals with very weak solution of metaphosphate of soda with a trace of potassium chloride.

(*c*) Two of the strong lateral roots in a plant were cut *in situ* and irrigated with well-water.

Fig. 4.

Crotalaria juncea Linn., a sterile shoot showing the characteristic bushy habit. × 1/6.

No difference was, however, noticed in the treated plants for about a couple of weeks after which curiously enough all of them started flowering. The control was without any flower.

These preliminary results have indicated the suspicion to be correct. It is proposed, therefore, to repeat this experiment on *rahar* and extend it to other crop-plants during the ensuing season.

I am much indebted to Rao Bahadur Viswanath (Imperial Chemist, Imperial Institute of Agricultural Research, Pusa) for certain useful suggestions.

A New Variety of Black Gram or *Urid* (*Phaseolus mungo*, Linn.).

TWENTY-FIVE types of black gram (*Urid*) have been described by R. D. Bose.[1] In the course of the examination of certain pulses at the Millets Breeding Station, Coimbatore, a new type from Malabar not described by Bose was met with. It is classifiable under "Section 2.—Black seeded types, sub-variety Niger (Bose)". The following is a detailed description of this type.

Habit: Semi-erect, profuse branching, stem furrowed, covered with long brownish hairs pointed downwards, stems green with purple splashes here and there. *Leaves*: Trifoliate, small, ovate, acuminate, leaflets ovate, entire, light green, petioles—long, hairy, channelled, sometimes purple streaked. *Flowers*: In axile racemes, peduncle purplish. Flowers lemon-yellow, back of standard purple tinged at the top, calyx purple tinged. *Pods*: Erect to sub-erect, cylindrical, unripe pods dark purple with a green tinge at the tip. Pods covered by brownish hairs pointed upwards. Dry pods dark brown in colour. *Seeds*: Oblong, small about $\frac{1}{6}$ of an inch long, flattened at both ends, black, dull, (grey back-ground with heavy black marbling).

It will be noticed that this type is characterised by its purple pods. Purple colouring on the pods of pulses is common. Some red grams have this whole or in bands. Similarly in *Dolichos lablab* this colour is whole or localised in the periphery of pods. In green gram, purple along the suture line is noted. In cowpea purple podded varieties are common especially from Malabar. These manifestations of pod purple are mendelian in behaviour. It is therefore interesting to record this new purple podded variety in black gram of potential use in hybridisation.

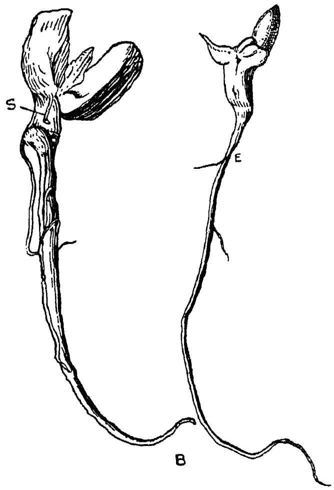
A Rare Instance of Poly-Embryony in *Arachis hypogæa*, Willd.

THE occurrence of more than one embryo in a seed has been recorded by various authors from as early as 1719. Many species of various families in both Dicotyledons and Mono-cotyledons have been known to exhibit the phenomenon. It is prevalent among the common species like *Syzigium jambolanum* (*Myrtaceæ*), *Syzigium* spp. (Tiwary, 1926), *Citrus aurantium* (*Rutaceæ*) and *Mangifera indica* (*Anacardiaceæ*). In *Papilionaceæ*, poly-embryony has been noted in *glycine hispida* (Owen, 1928). But it has

A. Germinating groundnut seed showing two main roots.

not been noticed, till now, in the groundnut, even though about a million groundnut plants have been examined during the last five years. Earnst (1918), Coulter, Barnes, Cowles (*Text-Book of Botany*) recorded a number of instances of poly-embryony.

While germinating a number of varieties of groundnut for root-tips, the authors observed that one seed of the variety "Bassi" was found to produce two radicals (Fig. A). Dissection of the seed revealed two seedlings. The bigger one was quite normal and the smaller had two thin, unequal cotyledons and a normal plumule. In the seed, the cotyledons of the smaller seedling were enclosed in between those of the bigger



B. Two seedlings separated. *E.* Extra seedling. × 2
S. Stalk by which the additional seedling is attached. × 2

one. At the top of the hypocotyl where the two cotyledons meet, there was a funicle-like structure connecting the hypocotyl of the extra seedling (Fig. B). Besides this, no other structure connecting the two seedlings was found.

The sources of the additional embryo or embryos are many and the correct origin could be determined best in the embryo-sac stage, which, in this instance, was not available.

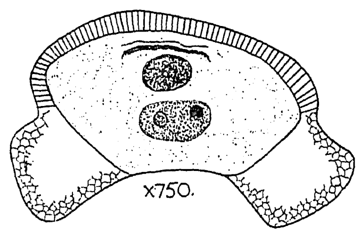
A Note on the Shedding Condition of the Pollen Grains of *Pinus longifolia* Roxb.

POLLEN grains of all the species of *Pinus* so far investigated show two prothallial cells, one generative cell and one tube nucleus at the time of shedding (Schnarf,[1] p. 25). The only exception so far recorded is that of *Pinus longifolia* where Sethi[2] (see p. 133) reports that "Two prothallial cells are cut off while the pollen grain is still within the sporangium. These cells are more evanescent perhaps than in the other species of *Pinus* because they disorganise very soon and the pollen at the time of shedding stage shows no indications of them."

From this statement one would conclude that the development to form the tube and generative nuclei does not occur *in* the male cones. On further enquiry Dr. Sethi wrote that the mature pollen is only three-nucleate at the time of shedding and that the division to form the tube and generative nuclei occurred on the nucellus. As there are several cultivated trees of *P. longifolia* at Agra, it was suggested by Dr. P. Maheshwari that I should section some material to ascertain this point more definitely.

The first two divisions of the microspore nucleus result in the cutting off of two prothallial cells. As stated by Sethi these become flattened and disorganised very early. *The nucleus of the pollen grain divides*



A mature pollen grain of *P. longifolia.*

once again producing the tube and generative nuclei. The generative nucleus is smaller than the tube nucleus and takes a very dark stain with hæmatoxylin. It organises into a definite cell by gathering some cytoplasm around it. In spite of the ephemeral nature of the prothallial cells I could still find some favourable preparations in which all four nuclei were clearly distinguishable (see Fig.). I feel inclined to think that the material sectioned by Dr. Sethi was a little too young. The tube nucleus assumes an irregular shape at maturity.

I am indebted to Dr. P. Maheshwari for his kindly examining my preparations and confirming these observations.

On the Peculiar Apertures in the Vertebral Centra of *Hemidactylus flaviviridis* Rüppel.

In the Patna Session (1933) of the Indian Science Congress, Mookerjee and Das read a paper[1] before the Section of Zoology on the presence in *Typhlops braminus* of an aperture in the middle of the ventral surface of the centrum of each vertebra towards the anterior half. Later, Mookerjee[2] published a paper in the *Proceedings of the Zoological Society* about them. He claims that these apertures have been recorded for the first time by him. Apparently, nobody after him has so far mentioned any other animal which shows these apertures, and hence I should like to mention the case of another Indian reptile, where similar apertures are present.

For the last two years, I have been engaged in an intensive study of the Bionomics, Anatomy and Distribution of the common Indian House-Gecko, *Hemidactylus flaviviridis* Rüppel. my purpose being to supply a detailed monograph for the Series "Indian Zoological Memoirs". During the course of this work. I have prepared alizarin-stained skeletons of every stage of this gecko from the just-hatched young one to the adult. In all cases, my preparations show the presence of two apertures on the ventral aspect of each vertebral centrum, these being placed one on each side of the median line. The apertures appear to serve for the passing in of blood-vessels and are quite unmistakable. when viewed under the lower magnifications (20-40) of a microscope. It is remarkable that the apertures in this case are *two*, and not one on each centrum, as described by Mookerjee for *Typhlops*. A detailed account of the main peculiarities of the endoskeleton of *Hemidactylus flaviviridis* is in course of preparation and will be published shortly elsewhere.

On the *Modus operandi* of Certain Ossicles in the Gastric Armature of Decapod Crustacea.

Mocquard[1] (1883), Pearson[2] (1908) and Patwardhan[3,4,5,6] (1934–35) have pointed out that the active movement of the gastric armature in *Decapoda* is brought about entirely by the anterior gastric muscles. Huxley[7] (1880) stated that the operation is effected by the anterior as well as the posterior gastric muscles. But the author[8,9,10] is of opinion that the active movement is the result of the contraction of the posterior gastric muscles, while the anterior gastric muscles and the cardio-pyloric constrictor muscles are mainly concerned in the restoration of the armature to its position of rest.

If the anterior gastric muscles were mainly responsible for the collision of the three teeth-bearing ossicles as suggested by Mocquard (1883), Pearson (1908) and Patwardhan (1934–35), one of the most essential factors, namely, the pressing down of the urocardiac tooth, to meet the colliding zygocardiac teeth could not be accomplished due to the reverted disposition of the propyloric ossicle (Figs. 1, 2 and 3, P.P.). For bringing the urocardiac tooth downwards, the posterior border of the propyloric ossicle which is bent over to the anterior side, has to be drawn backwards. This is possible only by contraction of the posterior gastric muscles. The anteriorly directed posterior border of the propyloric ossicle is wedged in between the exopyloric ossicles which give attachment to the posterior gastric muscles. The contraction of the said muscles results in pulling back the propyloric ossicle which, owing to the roof of the cardiac chamber, presses down the urocardiac tooth to meet the zygocardiac teeth.

The suggestions of Pearson (1908) and Patwardhan (1934–35) seem to have been entirely influenced by the statement of Mocquard (1883) who observed the action of the anterior gastric muscles in a living *Stenorynchus* having a remarkably transparent carapace. The author is of opinion that a re-investigation of *Stenorynchus* is desirable. In the fresh-water crayfish, *Astacus*, *Portunus*, American lobster, lobster, *Cancer*, *Nephrops* and *Paratelphusa*, described by Parker[11] (1876), Huxley (1880), Vitzou[12] (1882), Herrick[13] (1895), Williams[14] (1907), Pearson (1908), Yonge[15] (1924), Patwardhan (1934–35) respectively, the pro-

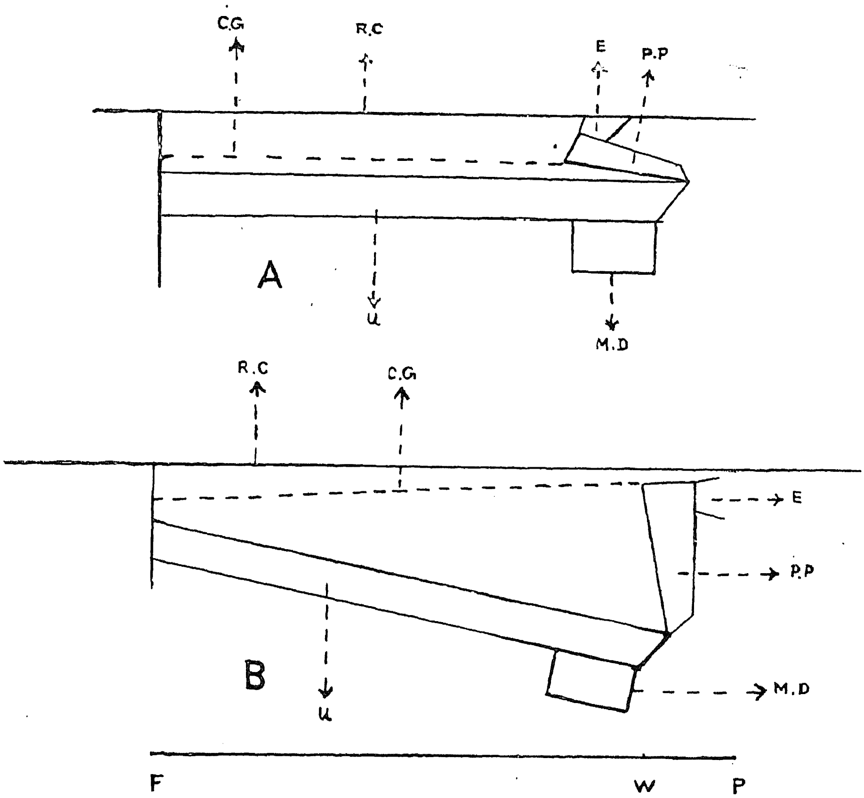

Fig. 1.

To show the action of the urocardiac ossicle.

A—Position at rest; B—Position at action.

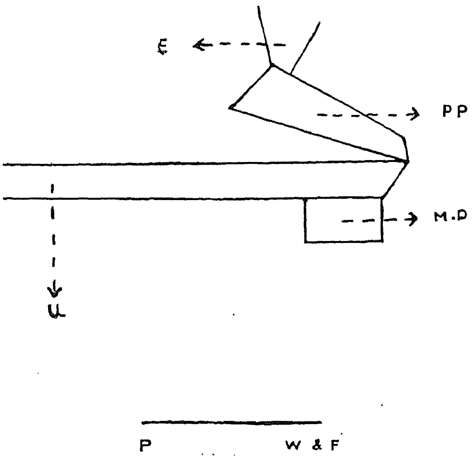

Fig. 2.

To show the action of the propyloric ossicle.

pyloric ossicle is definitely of a reverted disposition. Hence active movement of the gastric armature is possible only by the contraction of the posterior gastric muscles as indicated in Fig. 1, A and B.

Both the urocardiac and propyloric ossicles represent levers of the second order. In the case of the urocardiac ossicle (Fig. 1, A and B) the fulcrum is situated at its attachment with the mesocardiac ossicle while the power is applied at its hindermost extremity just behind the urocardiac tooth, by the anterior border of the propyloric ossicle. The power is the result of the contraction of the posterior gastric muscles and transferred to that point by means of the exopyloric and propyloric ossicles. The work is performed in the region of the urocardiac tooth. In the case of the propyloric ossicle (Fig. 2) the fulcrum is at the attachment of its anterior border with the hind end of the urocardiac ossicle and the power is applied by the exopyloric ossicles at its posterior border, while the work is done at a point near the fulcrum in pressing down the urocardiac tooth.

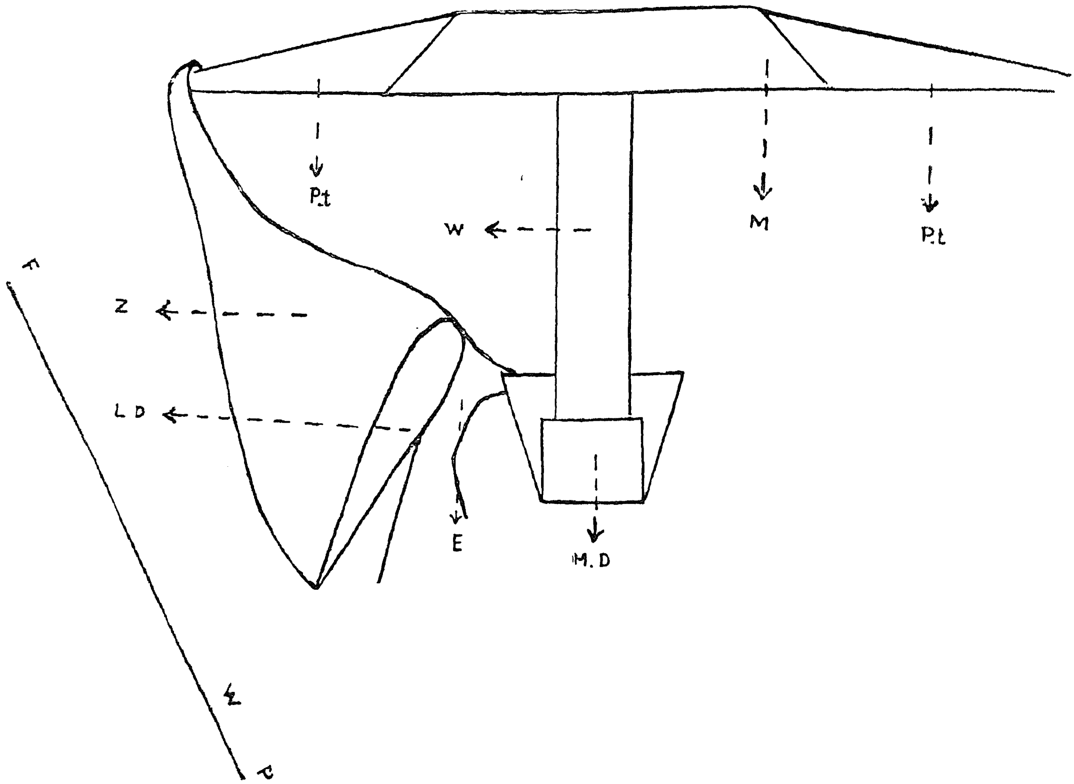

Fig. 3.

To show the action of the zygocardiac ossicle.

C. G.—Cardiopyloric Constrictor muscles; E.—Exopyloric ossicle; F.—Fulcrum; L. D.—Zygocardiac tooth; M.—Mesocardiac ossicle; M. D. Urocardiac tooth; P.—Power; Pt.—Pterocardiac ossicle; P. P.—Propyloric ossicle; R. C.—Roof of the Cardiac chamber; U—Urocardiac ossicle; W.—Weight; Z.—Zygocardiac ossicle.

Pearson (1908) on the supposition that the operation of the armature is effected by the anterior gastric muscles, locates both the point of application of power and fulcrum at the place of articulation of the zygocardiac ossicle with the outer end of the pterocardiac ossicle, while the work is turned out at the zygocardiac tooth and describes the action of the zygocardiac tooth as that of a lever of the second order considering the zygocardiac and exopyloric ossicles as a single bar. With the conditions described by him neither the zygocardiac ossicle with the exopyloric is a lever of the second order, nor is movement possible when power acts at the fulcrum. But if the power were to act at the exopyloric ossicle—as it should by the contraction of the posterior gastric muscles—then the action of the combined ossicles is that of a lever of the second order, with the fulcrum at the anterior end of the zygocardiac ossicle, the work being turned out in the region of the zygocardiac tooth and the power being applied at the exopyloric ossicle as illustrated in Fig. 3.

The Presence of Uncinate Processes on the Ribs of a Lacertilian.

UNCINATE processes are present in Birds, in some Temnospondyli among Stegocephalia, in the Rhynchocephalia, and in the Crocodilia.[1] Besides *Sphenodon* and crocodiles, they have not been recorded so far in any other living reptile. It is interesting, therefore, to mention their presence in a common Indian Lacertilian.

While making a detailed study of the endoskeleton of the housegecko, *Hemidactylus flaviviridis* Rüppel, I found that four anterior ribs bear such processes. These ribs are borne on the fourth, fifth, sixth and seventh cervical vertebræ and are partially hidden by the sternum and the pectoral arches. The processes themselves are extremely delicate and usually break off in the common methods of the preparation of skeleton. They, however, become quite distinct in an alizarin-stained skeleton.

The point is an important one, as it adds one more fact to the resemblances of some of the least specialised Lacertilia to *Sphenodon* and may be significant in the discussion of the latter animal's affinities. As is well known, some authorities[2] regard *Sphenodon* as the sole living representative of a primitive order of the Reptilia and consider it to be equal in rank to the other orders of this class. As opposed to this view, other zoologists[3] think that the differences between some Lacertilians and this animal are "not so great as to justify placing it in a separate order, but, on the contrary, it should be included in the Lacertilia."[4]

Incidentally, I might also take this opportunity of mentioning that Bhatia and Dayal[5] are wrong when they say, "The vertebral column in *Hemidactylus* is composed of 6 cervical, 5 thoracic, 15 lumber, 2 sacral, and large number of caudal vertebræ." Careful counting in alizarin-stained skeletons shows that the cervical vertebræ are eight and the lumbars thirteen, the total number of precaudal vertebræ being 28. These numbers also appear to tally remarkably with those of *Sphenodon*, as given by Howes and Swinnerton,[6] *viz.*, 8 cervical, 3–4 thoracic, 13–14 lumbar, and 2 sacral vertebræ, making a total of 26–28 precaudals. The difference in the numbers of the thoracic and the lumbar vertebræ of these two animals can be explained by the facts that the sternum in *Sphenodon* has no posterior continuations like that of *Hemidactylus* and that two of the thoracic ribs in the latter animal are connected to these continuations.

The Hosts of *Eupelmus tachardiæ* How.

MAHDIHASSAN[1] under the heading "Specificity of parasiticism by *Eublemma amabilis*" raised several issues, but chiefly accused Glover for making "the glaring statement" that *Eupelmus tachardiæ* is "inimical to lac itself," and asserts that he has definitely proved it to be a parasite of *E. amabilis* caterpillars.

Replying to the above Glover and Negi[2] stated that during the last eight years many miles of lac encrustation and many thousands of *E. amabilis* larva had been examined at the Indian Lac Research Institute and that in no instance had *E. tachardiæ* been found

parasitic on *E. amabilis*, but that it had always been found endo-parasitic on the lac insect *Laccifer lacca* and ecto-parasitic on the larva of *Microbracon greeni* syn. *Microbracon (Bracon) tachardiæ*. In support of this contention a number of publications of the Lac Research Institute were cited and in particular the *Proceedings of the Indian Science Congress*, 1929 and 1933, which Mahdihassan appears to have overlooked.

Mahdihassan[3] makes the following statement "'some one has said what I say thrice is right'; acting according to the principle Negi and Glover have repeated what they have asserted twice before.[2,3] While they stress the point it is the third time their claim appears in print,—I beg equally to emphasise, thrice have they neglected to bring forth any illustrations or details with regard to the life-history of the insect or any objective information."

The *Abstract of the Proceedings of the Science Congress*, 1933, is fairly detailed and is quoted in part in the next paragraph: comparison of this abstract and Mahdihassan's statement above is interesting.

"The chalcid *E. tachardiæ* (syn. *B. annulicaudis*) is primarily an endo-parasite of the lac insect and an ecto-parasite of the full fed larva, pre-pupa and early pupa of *M. greeni* (syn. *E. tachardiæ*) a parasite of *E. amabilis* larva. The chalcid oviposits on the stages of *M. greeni* only if covered with a cocoon ......superparasitism and laying of more than one egg by the female on the same host occurs......but in either case only one egg develops to the adult. The chalcid first deposits the egg on the host and paralyses it afterwards by several stings......oviposition and longevity is described. The chalcid seems to have 14 theoretical generations in a year based on monthly life cycles."

Mahdihassan in spite of the *Abstracts of the Indian Science Congress* and other publications of the Institute, particularly the *Annual Report for the Year* 1930–1931, challenges us to produce figures and life-history data to substantiate our claim. For this reason in spite of the fact that the paper on *Eupelmus tachardiæ* has not yet been sent for final publication, we reproduce here a photograph of one of the figures shown at the Science Congress in 1933 and quote the following data.

During the last eight years during regular routine examination of lac samples a considerable number of cases have been observed of *E. tachardiæ* parasitic on both *M. greeni* and *Laccifer lacca*. In the Science Congress 1929 paper, Gupta, Negi and Misra stated that a specimen of *E. tachardiæ* had been reared from the larval stage parasitic on *Z. jujuba* lac, Mathurapur, Bengal, in March 1927, and that since then a number of males and females of this chalcid had been reared from larvæ and pupæ parasitic on lac insects at Namkum, but that it had never been found parasitic on *E. amabilis*. During the year 1930–31 *E. tachardiæ* was artificially bred in the Insectary on *M. greeni* larvæ which had spun cocoons in small glass capsules. The following life-history data were obtained, and quoted by Negi and Gupta at the Indian Science Congress, 1933.

Month in which life-history began	Egg Stage	Larval Stage	Pupal Stage	Total cycle
April 1930 ..	..	..	7 days	..
May 1930 ..	1 day	8 days	8 days	17 days
June 1930 ..	1 day	7 days	8 days	16 days
July 1930 ..	1 day	10 days	8 days	19 days
August 1930 ..	..	..	..	..
September 1930 .	..	..	7 days	..
October 1930 ..	..	..	16 days	..
November 1930 ..	..	..	34 days	..
December 1930 ..	5 days	40 days	19 days	64 days
January 1931 ..	3 days	31 days	14 days	48 days
February 1931 ..	6 days	35 days	12 days	53 days
March 1931 ..	..	..	11 days	..

In the above table the complete cycles are from *eggs laid in the Laboratory on* M. greeni *larvæ as host: where only the pupal stage is given it is taken from larvæ collected from the Field parasitic on* L. lacca.

We prefer to leave the reader to judge whether our claim that *E. tachardiæ* is parasitic on *L. lacca* and *M. greeni* based as it is on 8 years regular routine examination of lac samples, entailing the annual examination of over 100,000 lac cells and many thousands of *E. amabilis* larvæ, and further based on the actual breeding of *E. tachardiæ* on *M. greeni* in the Laboratory, has greater justification than Mahdihassan's claim that *E. tachardiæ* is parasitic on *E. amabilis* based on a single and rather doubtful instance.

The instance cited by Mahdihassan of *E. tachardiæ* parasitic on *E. amabilis* is as follows:—A larva was found attached to the body of an *E. amabilis* caterpillar, it pupated the following day. From our experience it seems possible that the *E.*

tachardiæ larva which was within a lac cell close to an *E. amabilis* larva was dislodged from its actual host *L. lacca* while dissecting the encrustation and came to lie

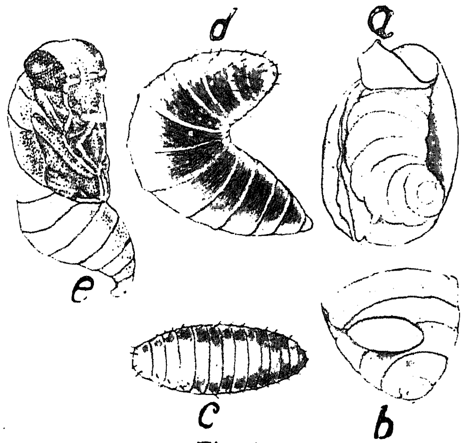

Fig. 1.

(*a*) A *Microbracon greeni* cocoon opened to show the paralysed *B. tachardiae* larva and the pencils and punctures formed between the larva and its cocoon as a result of the *E. tachardiae* (*B. annulicaudis*) pricks.

(*b*) The *E. tachardiae* egg lying over the posterior end of the *M. greeni* larva.

(*c*) Just hatched larva of *E. tachardiae*.

(*d*) Nearly full fed *E. tachardiae* larva (details not fully shown).

(*e*) The *E. tachardiae* prepupa casting the larval skin to turn into pupa.

on the *E. amabilis* larva before it was observed by Mahdihassan.

If Mahdihassan is still not fully convinced may we suggest that he try to breed *E. tachardiæ* in the Laboratory on both insects, *M. greeni* and *E. amabilis* and he will discover for himself that the former is a host of *E. tachardiæ*.

As regards Mahdihassan's other observations, we prefer at present to disregard them as they are of secondary importance and merely confuse the issue of the present discussion regarding the host of *E. tachardiæ*.

We should like to point out, however, that our specimens of *Eupelmus tachardiæ* were identified by Dr. Ch. Ferriere of the Imperial Bureau of Entomology, an expert on the *Chalcidoidea*.

Alkaline Quartz-Dolerites, from Bijawar, and Their Chemical Relationships.

FOR some time the author has been working on the trappean[1] rocks which are found associated with the Bijawar system in the type area. Certain interesting results of chemical nature have been obtained and it has been thought desirable to publish them in the form of a short communication. The results of detailed investigation will be published later. A collection of rock specimens was made from intrusive masses occurring in the central part of the Bijawar outcrop. Under the microscope the rocks present a very decomposed appearance and are found to be medium-grained quartz-dolerites with a pale brown pyroxene and plagioclase felspar as their main constituents. Uralite, chlorite, biotite and epidote occur as secondary minerals. Micropegmatite occurs in the interstices, and needles of apatite are generally present. Iron oxides are very prominent and have crystallised later than the pyroxene and plagioclase. The pyroxene has been considerably altered to uralite and the plagioclase looks extremely clouded. Some plagioclase laths are so much crowded with decomposition products that they are indeterminable. Fresh felspar is rare, but when it is present it gives an extinction angle corresponding to labradorite.

(1) Quartz-dolerite, Chopra, Bijawar. (2) Quartz-dolerite, Rampur, Bijawar. (3) Quartz-dolerite, near Bajno, Bijawar. Analyst: M. P. Bajpai. (4) Average of 1, 2, and 3. (5) Average Deccan basalt, H. S. Washington's analyses, 4, 12, 13, 15, 16 and 23 in *Bull. Geol. Soc. Amer.*, 1922, **33**, 774. (6) Average spilite, *Geol. Mag.*, 1930, **67**, 9.

Ilmenite, too, has been altered to leucoxene. Ophitic and sub-ophitic textures are well developed.

Three chemical analyses of the Bijawar quartz-dolerites (Nos. 1, 2 and 3) and their average analysis (No. 4) show that there is not much chemical difference between the Bijawar quartz-dolerites and Deccan basalt (No. 5) except that the percentage of Na_2O is considerably higher in the former (6·02 per cent.) than that in the latter (2·27 per cent.).

The percentages of silica, alumina, ferrous oxide, lime and magnesia in the average analysis of the Bijawar quartz-dolerites compare well with those of the same constituents in the Deccan basalt. Richness in alkali is a remarkable chemical feature of the Bijawar quartz-dolerites.

Except for the percentages of CaO, MgO and TiO_2 the analyses of the Bijawar quartz-dolerites compare fairly well with an average analysis of spilite (No. 6). In containing a high amount of soda and low percentage of potash, the Bijawar rocks exhibit some of the important chemical characteristics[2] of spilites.

T/1, T/2, T/84, T/86, T/59–Quartz-dolerites and T/14 Basalt—from neighbourhood of Gwalior. Analyst: M. P. Bajpai, *Jour. Geol.*, 1935, **43**, No. 1, 69. (7) Average of the six Gwalior rocks. (8) Average of three Bijawar quartz-dolerites. (9) Newer dolerite from N.E. of Belma. Analyst: L. A. N. Iyer, *Rec. Geol. Surv. Ind.*, 1932, **65**, pt. 4, 528.

The quartz-dolerites from Gwalior, which have been previously studied[3] by the author, and those from Bijawar are composed of the same mineralogical constituents. The presence of micropegmatite and ophitic and sub-ophitic textures, and indications of late crystallisation of iron oxides are three very important microscopic characters common to the rocks from both the areas. Table II shows that, as far as the percentages of silica, alumina, ferric oxide, magnesia and lime are concerned, there is a close chemical agreement between the Gwalior and Bijawar quartz-dolerites. It has already been shown[4] by the author that the Gwalior trap contains a higher amount of soda than the Deccan basalt. High soda content in the Gwalior and Bijawar rocks, together with fairly uniform percentages of other constituents, indicate a close relationship between them. Average soda in the Gwalior trap is 4·47 per cent. and that in the Bijawar dolerites 6·02 per cent. The maximum amount of soda in the Gwalior and Bijawar rocks is 5·17 per cent. (No. T/84) and 6·33 per cent. (Table I, No. 2) respectively. The relatively higher amount of soda in the Bijawar quartz-dolerites seems to be related with their highly altered state because in other respects they closely resemble the quartz-dolerites of Gwalior.

Holland, in his paper, "On some Norite and associated basic dykes and lava-flows in Southern India" has shown that the trappean rocks which are found associated with the Gwaliors and Bijawars remarkably agree[5] with the augite-diorites of the Cuddapah lava-flows in petrological characters. A chemical study of the rocks from Gwalior and Bijawar shows that richness in alkali seems to be a regional feature of these supposed equivalents of the Cuddapah

lavas. Recently L. A. N. Iyer has described some "Newer dolerites" from Singhbhum which also resemble[6] Holland's augite-diorites. It is interesting to note that they also show alkaline tendencies, the total of soda and potash being considerably high in all the analysed[7] specimens of the Newer dolerites. Iyer's specimen from Belma is particularly rich in alkalies (Table II, No. 9).

The Bijawar quartz-dolerites contain an abnormally high amount of soda. An advanced stage of decomposition of their plagioclase felspars arouses suspicion that the enrichment in soda is probably due to the partial albitization of the original labradorite felspar. The felspars (with their decomposition products) and the pyroxene are under detailed investigation.

Sir Montagu Webb and Silver.

SIR MONTAGU WEBB has drawn my attention to what he describes as one little inaccuracy on page xi of my paper on "Energy and Economics"[1]. I represented him as having *put aside for a time* his advocacy of an increase in silver currency. He writes that he is, as a matter of fact, pressing with greater vigour than ever for co-operation with President Roosevelt in re-opening the world's mints *to the people* to the free coinage of *unlimited legal tender silver coins*.

Actually I had no intention of suggesting that Sir Montagu had in any way abated his campaign. I merely meant that in the particular case of Karachi, silver was not specifically mentioned. If I had said "for the moment" instead of "for a time" it might have better conveyed my meaning. In any event I am glad to have the opportunity of correcting a possible false impression.

I may mention that Sir Montagu has just sent me the first five numbers of his new bulletin entitled "*Better Money*" which are full of valuable information on the subject of Monetary Reform. He tells me that he will be glad to send copies to any student of this, the most important problem of the day.

Magnetic Susceptibility of Ice.

IN a letter[1] regarding the diamagnetic susceptibility of water polymers, the susceptibilities of (H_2O), $(H_2O)_2$ and $(H_2O)_3$ have been computed using the temperature-susceptibility data of Cabrera and Fahlenbrach and the polymer abundance data at different temperatures obtained by Ramakrishna Rao. The computed value for the susceptibility of ice works out to be $-0\cdot7080 \times 10^{-6}$. At that time I was not aware of any experimental value for the susceptibility of ice. Recently, however, my attention has been drawn to a paper by Ishiwara[2] where the susceptibility value for ice is given as $-0\cdot699 \times 10^{-6}$. The calculated value shows a deviation less than 1·5% from the observed value; this in itself is a striking agreement in support of the theory. Ishiwara has further observed that the susceptibility of ice remains unaltered between −120°C. and 0°C. This would require the polymer constitution of ice to remain fairly constant between −120°C. and 0°C. It is quite probable that in ice no variation occurs, for it would demand a rearrangement of the crystal lattice. Modifications of ice, *viz.*, ice II, III, V and VI observed by Tammann and Bridgman at low temperatures and very high pressures are perhaps due to this cause. But ice I, *i.e.*, ordinary ice, cannot possibly be modified by the lowering of temperature alone. Such a hypothesis would explain the observed constancy of the magnetic susceptibility of ice between −120°C. and 0°C. at atmospheric pressure. It must, however, be admitted that the above assumption requires experimental confirmation.

Chemistry in the Customs Department.*

By H. B. Dunnicliff,

Special Chemical Adviser, Central Board of Revenue, Lahore.

Introduction.

In 1905 the attention of the Government of India was drawn to the inferior quality of country spirit consumed by the Indian people and Lt.-Col. (afterwards Sir Charles) Bedford, I.M.S., was appointed to investigate matters. Assisted by Messrs. Jenks and Day and two Indian Laboratory assistants, he carried out the pioneer work in India on spirit examination and estimation. They studied the contamination of spirits with copper and zinc and prescribed easy tests for their detection. They also developed methods for distinguishing between illicit spirits and those distilled under Government permits, mainly by the detection of common impurities present, and prepared an official Technical Excise Manual. This work had the dual effect of improving country spirits and conserving excise duty.

Determination of Spirit Strength.

The term "Spirits" was used to mean the compound which is most commonly produced in fermentation processes and which is properly called "ethyl alcohol" or more commonly just "alcohol". Ethyl alcohol is, however, only one of a series of compounds having similar or related properties and the term "Spirits," both in Great Britain and India, now includes pure methyl alcohol which is produced in large quantities by several commercial processes.

In India, the term "Spirits" covers all alcohols the proof strength of which can be readily ascertained. Such alcohols must be miscible with water in all proportions and, at a temperature of 51° F. have, in the pure state, a specific gravity relative to water of not more than 0·923. These conditions are satisfied by methyl, ethyl, normal-propyl and isopropyl alcohols.

The spirit strengths are determined by two methods, the hydrometer and the pyknometer or specific gravity bottle.

Sikes Standard Brass Hydrometers were originally used but Sir Charles Bedford stated that they are not very suited to Indian conditions and he prepared tables for the use of instruments made of glass and, in a simple mixture of alcohol and water, the amount of alcohol present can be determined directly by these instruments.

If, however, some other substance is present in solution, such as sugar or colouring matters, the direct reading of the instrument no longer gives the spirit strength and the spirit strength is said to be "obscured" by these additional substances. Obscuration always results in an apparent lowering of the amount of alcohol present and consequently in the loss of revenue if not properly calculated and adjusted. Its determination in alcoholic liquors is one of the important functions of customs and excise chemists.

In obscured liquids, spirit strength is determined by distilling off the alcohol and finding the spirit strength of the distillate by the hydrometer or pyknometer. In some cases, the distillate contains substances other than spirit such as essential oils or volatile compounds like camphor and these have to be separated before the correct spirit strength can be reported.

For some years spirit strengths were determined in the Gauging Departments of Custom Houses and Mr. Jenks who, until 1928, was Chemical Examiner for Customs and Excise at the Calcutta Custom House was called upon to investigate and report on the best method for the determination of the spirit strength and obscuration of spirituous liquors imported into India.

The United Kingdom procedure using the Sikes brass hydrometer was ultimately adopted and all ports have their instruments adjusted at Calcutta where there are standard instruments, which are periodically tested at the Government Laboratory in London.

Denaturation.

Alcohol is an essential constituent of many commercial articles such as "methylated spirits", varnishes, a number of medicinal preparations and many others.

In order that alcohol may be available for arts and industries as well as for domestic purposes, it must be cheap but it must be "denatured," *i.e.*, made too unpleasant to drink. Hence much work has been done to discover suitable substances to add to drinkable pure or nearly pure alcohol, the so-called "rectified" or "silent" spirits, to make them so nauseating and repulsive that even the strongest palate could not tolerate the taste. Substances added to pure alcohol for this purpose are called "denaturants".

The selection of an official denaturant for India was investigated by Sir Charles Bedford and Mr. Jenks with the co-operation of Messrs. D. Waldie & Co.

The properties required of an ideal denaturant are very exacting and may be detailed as follows. It must be a combustible volatile liquid, soluble in alcohol, having an unpleasant taste and smell and not be easily separable from the spirit by physical or chemical means. It must not be poisonous nor have any injurious effect on the human body and must be available in large quantities at low rates.

Very few substances have all these properties and a fortune awaits the discoverer of new and better denaturants than those at present available.

Spirit is denatured in India by the addition of two substances: the first is one of the distillation products of old vulcanised rubber, such as old motor tyres, and is called "light caoutchoucine," the other is "pyridine bases of mineral origin". (Pyridine bases can be made from animal nitrogenous refuse but their use is not permitted.)

One half per cent. of each of these substances is added to imported rectified spirits in the Custom Houses before the spirit is issued for general use as "denatured spirit" or, as it is often erroneously called "methylated spirit".

* An abridged version of a public lecture given at the meeting of the Twenty-Second Indian Science Congress on January 5th, 1935, in the Senate Hall of the Calcutta University.

Denaturation by other means, such as the addition of wood naphtha, is only allowed by special permission in the interests of the development of certain industries and in the case of certain IMPOTABLE preparations. Such denaturants "earmark" the spirit as "specially denatured" and the chemist is responsible for their detection.

PROOF SPIRIT.

The way in which alcoholic content is described, *i.e.*, in terms of "proof spirit," has a peculiar origin. If a light is put to alcohol, it will burn, even when it contains fairly large quantities of water. In early days, if a specimen of alcohol was poured over gunpowder and then ignited, the alcohol was said to be "under proof" if the flame ceased burning without igniting the gunpowder and "over proof" if, under these conditions, the gunpowder burst into flame. The weakest solution which just permitted the gunpowder to inflame was called "proof spirit". The strength of this spirit was accurately determined and spirit strengths are still described in terms of this arbitrary standard, *i.e.*, in degrees of proof spirit. A spirituous liquor is said to be 10° "under proof" if, from 100 volumes of that liquid, 90 (*i.e.*, 100 - 10) volumes of liquid of proof strength could be made. Thirty degrees "over proof" means that 100 vols. of that liquid could be diluted with water to give 130 volumes of proof spirit. One hundred volumes of pure alcohol would give approximately 175 volumes of proof spirit. Thus pure alcohol is 75° over proof. These values are sometimes described as percentages, for example, 30° over proof spirit is also said to be 130% proof.

POWER ALCOHOL.

One of the earliest investigations undertaken in the Customs Laboratories was an attempt to formulate a fuel for motor vehicles in an attempt to replace or supplement petrol. The Power Alcohol Committee appointed Mr. Jenks to carry out experimental work and he finally submitted proposals for the introduction of a fuel composed of 90% alcohol, if not less than 55° over proof, denatured with the usual denaturants and coloured with half a gram of methyl violet per gallon together with 10% of petrol, ether, benzol or other approved adjunct to act as anti-knock constituents.

ISOPROPYL ALCOHOL.

Complexity sometimes arises because the Government of India's definition of "spirit" differs from that of Great Britain in that it includes two more alcohols, normal and isopropyl alcohols. The former is not of much importance but the latter, isopropyl alcohol, called by various trade names such as "avantine," "petrohol" etc., causes difficulties as it is being used in increasing quantities in the manufacture of cheap perfumes, flavouring essences, toilet preparations and a number of other commercial products. Since this compound is not classed as "spirit" in England, cheap scents and other products like flavouring essences are often described in good faith as "free from spirit" while they contain isopropyl alcohol and, are therefore assessed to spirit duty on import into India.

Recently it was discovered that the standard chemical method for the determination of spirit strength known as the Thorpe and Holmes's method, is not reliable when isopropyl alcohol is present and a modified* form of the test has been worked out by two chemists at the Bombay Custom House and is in current use

WINES, ETC.

Some alcoholic beverages, *e.g.*, beer, porter, cider, are not tested directly, but they have to be identified. Wines not containing more than 42 degrees proof spirit, roughly 24% by vol. of alcohol, and perfumed spirits or scents are assessed by volume or gallonage.

Wines containing small quantities of medicinal substances are called "Medicated Wines". For Tariff purposes, they are assessed at a lower rate of duty than that charged on ordinary beverages containing spirit and they are classed in a separate category although, fundamentally, there is little difference between a medicated and a beverage wine. Wines containing very small quantities of medicinal substances are also sold as "aperatif wines" and claims are sometimes made for their preferential treatment as medicated wines. This is not permissible in Customs although Excise regulations allow them to be sold under a medicated wine licence in chemists' shops. An up-to-date list of medicinal, aperatif and beverage wines is maintained in all Custom Houses.

PROHIBITED AND RESTRICTED DRUGS.

Alkaloids such as morphine, cocaine and other habit-forming drugs have valuable medicinal properties and their total restriction is not desirable. The Health Committee of the League of Nations is attempting to regulate the traffic in such drugs without interfering with their use in medicines. In addition to these, a number of valuable restricted and prohibited drugs have been synthesised and the qualitative and quantitative examination of samples in pursuance of the Geneva Convention for the Regulation of Narcotic Drugs of 1925 and in the operation of the Dangerous Drugs Act is among the important duties of Customs analysts.

THE DEVELOPMENT OF THE CUSTOMS LABORATORIES.

Until 1912, the main commodity assessed to Customs duty by chemical means was "spirituous liquors". These were tested in the Custom Houses but any other imports requiring chemical examination were sent to the laboratories of the Chemical Examiners to the Local Government of the Presidency in which the Custom House was situated.

As time went on, the number of articles requiring chemical examination to provide for their correct assessment to Customs duty and the number of samples submitted increased and the complexity of the issues became more involved.

To deal with the work, a laboratory having a wider scope was opened in the Calcutta Custom House and Mr. Jenks was appointed to do all the excise work for Local Governments (except Bombay and Madras) and also to examine any Customs samples which might be submitted.

Further increase in the number of items in the Customs Tariff assessable to duty on the basis of chemical examination took place during the next fourteen years, until the range extended over foods, textiles, oils, building materials, jewellery, paper, minerals, dyes, patent preparations of all kinds and numerous other classes

***Vide Analyst*, 1935.

of goods and the necessity for a specially trained scientific staff became self-evident.

In 1926, the Government of India decided that it would be advisable to consider the establishment of laboratories in the Custom Houses at the other major ports: Bombay, Karachi, Madras and Rangoon, so as to expedite the work and have the testing carried out under the administrative control of the Collectors of Customs.

Mr. Jenks was directed to submit a scheme and, in 1927, laboratories at the Karachi and Rangoon Custom Houses were opened but the apparatus was limited and the equipment incomplete.

Mr. Jenks was put on special duty in 1928 to organise, furnish and equip the laboratories, to make recommendations regarding staff and to prepare a technical manual for the use of Customs chemists. Unfortunately, he suddenly fell seriously ill in July 1928 and had to leave India immediately.

His senior assistant Mr. (now Rai Sahib) M. N. Ghose, the present Chemical Examiner at the Calcutta Custom House, was put in charge of the laboratory but, in the following October, the Government of India appointed a special advisory officer to develop the scheme for the organization of Customs chemical work.

Laboratories suitably equipped for the purpose and staffed by qualified chemists have been fitted out in the Bombay, Karachi, Madras and Rangoon Custom Houses and the equipment at Calcutta expanded and improved. These laboratories are responsible for the testing of all samples sent for examination by the Appraisement and other Departments of the Custom House and the chemists in charge submit their reports, paying special attention to the interpretation of the Indian Customs Tariff. Each laboratory works under the direction of a Chemical Examiner or Assistant Chemical Examiner. These officers are under the administrative control of the Collector of Customs at the port and the technical control of a Central Officer entitled the Special Chemical Adviser to the Central Board of Revenue. At present, by the courtesy of the Punjab Government, that officer is located temporarily at Lahore where excellent laboratory and library conditions exist. From this Control Laboratory, standard methods of analyses are circulated, investigations are carried out and appeal cases and technical references are submitted for advice or discussion. All laboratories periodically send remnant portions of actual samples for comparative analysis, criticism, information and report. The Indian Customs Tariff is divided into ninety-one general items of which eighty-seven are in the Customs Tariff under twenty-two sections. Samples under more than half of these eighty-seven items can be submitted to the laboratories for test or opinion. When one considers the practically unlimited range of imported articles, a moment's consideration will give an idea the wide scope of chemical knowledge demanded of the Board's chemists if revenue is to be safeguarded. The Special Chemical Adviser visits all the Board's laboratories at least once a year and is in frequent personal contact with the Central Board of Revenue on scientific matters.

In addition to the routine work, the chemists contrive to find time to investigate new methods or modify existing ones in the interests of speed and efficiency and several articles on analytical and other subjects have been published in scientific journals. This phase of activity shows that the chemists take a lively interest in their duties and are anxious to keep in touch with or even in advance of accepted technical procedure. Though the duties of Customs chemists deal mainly with the examination of imported goods in order to allocate them to the correct items of the tariff, the work in the Custom Houses covers a still wider field.

MERCHANDISE MARKS ACT.

From time to time, samples are submitted for test to find out if they are correctly described. Importers of goods which are marked with inaccurate or misleading descriptions are liable to penalties under the Merchandise Marks Act.

For example, bottles of medicine such as quinine, stated on the label to contain a specified amount of the drug, may be found to be deficient in the essential constituent; pen nibs or gold or silver articles may be marked incorrectly as to their composition, *e.g.*, pen nibs may be marked 9 Kt. gold and found to be only gold washed; condensed milk stated to be made from full cream milk may be found to be made from skimmed milk; artificial butter or ghee described as "vegetable product" may be found to contain animal fat or hardened fish oil, etc. A wide range of textile goods and many other articles are submitted for test under this head.

Calcutta is the only laboratory which does Excise work for the Government of India and certain Indian States. A good many samples of fibres such as jute, hemp, sisal, aloe, flax, etc., are also examined for allocation to various items of the Import or Export Tariff.

CONTRABAND.

Another interesting function of the laboratories is the examination of contraband, such as opium and other restricted drugs such as cocaine, known to addicts as "snow", and the testing of certain imports under the Explosives Act or the Dangerous Petroleum Act. Matches are examined for yellow phosphorus and crackers for potassium chlorate and gunpowder.

If contraband opium is found to contain 3 per cent. of its most important alkaloid, morphine, it is sent to the Government Opium Factory at Ghazipur for the manufacture of morphine, codeine, etc., otherwise it is destroyed at the port. Cocaine which is seized by the Customs Preventive staff is kept in bond under an armed guard and a special chemist has been trained to manufacture from the contraband cocaine pure B.P. cocaine hydrochloride which is sold to Government Medical Departments or to other purchasers approved by Government for use in medicine and surgery. The impurities with which the drug is diluted, so that swindling in its illicit sale may be carried on, include synthetic drugs like aspirin and phenacetin and such commonplace substances as starch, Epsom salts or sugar.

SALT.

Originally the analyses of salt samples for the Salt Revenue Department were tested in the laboratories of the Chemical Examiners to local Governments but now all Government salt samples are tested in the Customs Laboratories and, during the non-co-operation movement in 1930, all samples of satyagraha salt were tested in the Board's Control Laboratory—the principal concern of Government being as to whether the

products contained impurities dangerous to human life. Salt is sometimes exempted from duty when used for certain manufacturing processes if it is rendered unfit for human consumption by "denaturing" it with napthalene or "hypo".

Salt imported and issued with the previous sanction of the Governor-General in Council for use in certain manufacturing processes such as glazing stoneware or curing fish is allowed to enter India duty-free.

FUMIGATION.

This extensive country is inflicted with many pests which seriously hinder agriculture and Government is very anxious to prevent the introduction of any new varieties. Hence, all imported living plants and certain seeds have to be disinfected at the ports by fumigation with prussic acid vapour before being sent to their consignees.

TRAINING OF YOUNG CHEMISTS.

From time to time one or other of our laboratories has been responsible for the training of chemists for special purposes and it is now decided that the laboratories of the Central Board of Revenue shall undertake certain testing work for certain other Government Departments, for example, the examination of oils for Indian Railways to enable them to classify them correctly under the various freight rates.

KINDS OF DUTY.

In general, Customs duty can be classified under three heads :—

1. Duty imposed purely for *revenue* purposes. This duty is levied on all goods whatever their country of origin.

2. *Preferential Revenue.*—This is collected for revenue purposes but there is a concession of part of the duty, usually 10 per cent. less for the United Kingdom or a British Colony or both, so as to give privilege to constituent countries of the British Empire. These preferential tariffs which have come into being as a result of the Ottawa Agreement have increased the analytical work because certain imports not previously chemically examined have now to be tested in the laboratory.

3. *Protective Duty* is the duty levied on goods imported into India with a view to safeguarding India's industries. Among these items are cheap printing paper, raw silk and silk waste and textiles containing specified percentages of certain constituents such as cotton, silk, artificial silk, etc., all of which have to be checked by chemical examination.

YARNS AND TEXTILES.

Yarn and textile fabrics yield a considerable amount of Customs duty. In 1930 and 1931, textiles made of artificial silk were assessed at a lower rate of duty than cotton piece-goods. Artificial silk was often substituted for cotton in imported piece-goods. This put Indian cotton manufacturers at a disadvantage, particularly on account of the attractiveness of artificial silk textiles and because artificial silk was not manufactured in India. To protect the Indian cotton industry, the Government of India increased the duty on artificial silk to a rate much higher than that on cotton goods.

Owing to foreign competiton, particularly from Japan, the Government of India has now levied protective duty on all kinds of piece goods and this has materially increased the analytical work as will be understood from the following examples, the classification of all of which depends on chemical examination ; the fibres mainly concerned being cotton, wool, silk and artificial silk and the difficulty of the work is much increased by the introduction of many classes of composite fibres.

Fabrics containing gold or silver thread are assessed at 50 per cent. *ad valorem*, whatever the rest of the material is made of. Fabrics not otherwise specified containing more than 90 per cent. artificial silk are assessable at different rates depending on whether they are or are not of British manufacture.

Woollen fabrics not otherwise specified containing not more than 90 per cent. wool, excluding felt and fabrics made of shoddy and waste wool, made in the United Kingdom are on the preferential list. Their examination involves (*a*) determination of wool and (*b*) the decision as to whether the wool is waste or shoddy.

Other items requiring reports from the laboratories are :—

Cotton fabrics not otherwise specified containing more than 90 per cent. cotton ; fabrics not otherwise specified containing more than 10 per cent. and not more than 90 per cent. silk ; the distinction between pure silk and silk noils and waste silk and many others.

While certain antimalarial alkaloids are imported free of duty, it is difficult to get the same privilege for any substance imported under a trade name for the same benevolent purpose. For instance, Paris Green, a basic arsenite of copper, is used for antimalarial purposes but, as it is employed in other industries, for example, as a pigment, it has to pay duty.

A number of painters' materials are examined, *e.g.*, genuine red lead, genuine white lead and genuine zinc white which have to conform with certain specifications and must be distinguished from the "reduced pigments" or pigments to which a cheaper material has been added to lower the price such as the mixing of barium sulphate with white lead or zinc white. A large variety of pigments are submitted for test including compounds of less common metals like zirconium, tungsten, etc. Manures, chemicals and various technical chemical products often furnish interesting chemical investigations.

MILK AND MILK POWDER.

Condensed milk and milk powders are liable to adulteration and milk products are analysed to find out if the original milk from which the condensed milk or milk powder was made contained the requisite percentage of fat. It is also important to know if other constituents have been removed and complete analyses are sometimes required to ascertain the protein or lactose values of the original milk.

DYES, ETC.

Synthetic dyestuffs made from coal-tar products and coal-tar auxiliaries used in dyeing have been included among dutiable goods. In 1927, as the result of a representation of the cotton mill owners, the Government of India abolished the duty but, in 1932, it was restored and, since then, coal-tar dyes and substances derived from coal-tar used in dyeing processes are assessed to duty at 10 per cent. either *ad valorem* or on different tariff values.

Customs chemists are required to find not only

the class to which a particular dye or auxiliary belongs, but sometimes to identify the substances as well. They are also required to test insoluble dyes, coal-tar lakes and other coal-tar pigments used for the manufacture of printing ink, etc., and which are assessed under a separate heading.

PLATED ARTICLES.

To encourage the electro-plating industry in India, a preferential duty has been imposed on electroplated articles, but the term "electroplating" has caused a good deal of trouble. Ordinarily it means a coating of noble metals like gold or silver on base metals, but there are cheap gold- and silver-washed articles as well as cheap jewellery which cost little and are showy but, on use, rapidly deteriorate and soon show the base metal foundation. The term "electro-plated" signifies articles having a "durable" coating of gold or silver and the criterion of "durability" has often presented difficulties. The words "gilt" or "rolled gold" are often stamped on such goods and the customs chemists are required to test them to detect violations of the Merchandise Marks Act and also to make the difficult decision in border line cases between gold-washed and gold-plated articles.

HYDROCARBONS.

Much work is sent to the laboratories under what may be called " petroleum products " or "hydrocarbons". This includes a wide range of commercial articles, commencing with dangerous petroleum and finishing with tar and other building and road-making materials derived from petroleum or coal. The appraisers also submit a wide range of lubricating oils and greases as well as fuel and kerosene oils and other illuminating oils for examination and report.

PAPER.

An item of the tariff which has caused a great deal of work is printing paper known as "cheap newsprint", containing not less than 70 per cent. of mechanical wood pulp. The other constituents are usually chemical pulp and loading and finishing materials. The analysis is carried out in two ways: (1) optical and (2) chemical. The former depends on the fact that mechanical wood pulp is stained yellow and chemical pulp is stained blue by iodine. The fibres are counted under the microscope. The chemical method depends on the fact that a constituent of mechanical wood pulp combines with phloroglucinol. The well-known method of Cross and Bevan has been standardised to Indian conditions in the Control Laboratory.

Sometime ago, starch could be imported duty free but now it is liable to duty of 15% *ad valorem* while flour or farinaceous food is dutiable at 25% *ad valorem* (except tapioca flour which has a Tariff value and necessitates its distinction in the laboratory from other flours). Since "cornflour" is practically pure starch, one has to decide under which head this has to be assessed. This is a function of the Collector of Customs but presumably he is driven to consider in what manner it is imported; in packets labelled as some sort of foodstuff, or in sacks, presumably for the textile or other industry, possibly to be packeted as a food later on after having paid the lower rate of duty!

Similarly toilet soaps and household soaps are assessed at different rates of duty.

A variety of "toilet preparations" are submitted for test and the high content of liquid paraffin or other mineral oil which occurs in some so-called "pure vegetable oil" hair preparations is surprising.

In these days of artificial products, many essential oils are made up of or synthesised from manufactured constituents and the distinction between the natural and the synthetic oil is one which presents considerable difficulty.

The complexity of the customs chemical work increases daily as the development of synthetic preparations for various industries increases. The identity of these compounds is hidden under non-committal trade names such as Kaffir Plaster, Kasenite, Lactoyd Sheet, Cremol, Ramasit, Pernisol, Purgatol, Asplit, Priemsal, Suma Carb, Ursol, Vimto, Silica sel and sometimes without any name or suggestive description. The composition of these patent preparations cannot be given for obvious reasons but such imports have to be examined in order to advise the Collector of Customs as to which item of the Tariff is involved. About 35,000 samples are examined annually but this gives no idea of the range of the work since, as will be seen from the examples quoted, the examinations are often of a complicated and specialised character.

It not infrequently happens that inter-portal discussions are involved and much investigation undertaken in order to define the category of a particular importation. This can scarcely be avoided owing to the want of precise definitions of many articles of commerce. This difficulty is overcome in various ways, often adopting certain limiting criteria which define the product, but it is clear that those limits must be finally acceptable to the trade before applying them to the material in question.

It will thus be seen that the work of the Customs chemists demands qualified analysts of more than ordinary ability and that Chemical Examiners must have a wide knowledge of the application of the products examined so that, on the one hand, revenue may be safeguarded and, on the other, business interests may get a fair deal.

With the exception of the writer, there are twenty-seven chemists working in the Board's Laboratories, all of whom are Indians and great credit is due to them for their honest and successful work in a difficult and critical field which yearly increases in scope and complexity.

Some Biochemical Factors of Disease Resistance in Plants.

By A. V. Varadaraja Iyengar, D.Sc., A.I.C., A.I.I.Sc.

(*Department of Bio-Chemistry, Indian Institute of Science, Bangalore.*)

THE ability of plants to withstand the effects of extremes of climate or the invasion of parasites is a highly variable quality. Thus, it is common to find a few plants which are able to resist these extraneous influences for considerable lengths of time while others succumb readily. The occurrence of such resistant types has been made use of by botanists, physiologists and plant breeders for diverse purposes. The factors that contribute towards this capacity are of much practical importance and may be classified under the two main heads :—(*a*) morphological or structural, and (*b*) physiological or biochemical.

Our knowledge of disease resistance is derived mainly from animal pathology, in which rapid advances have resulted in the development of immuno-therapy, leading to the protection of individuals from infection. The applications of serum-therapy, chemo-therapy and vaccines are the outcome of researches in the above field. Unfortunately, these procedures do not lend themselves to such fine manipulation with plants as in the case of animals. The reason for this lies in the essential difference between the two groups indicated by Quanjer.[1] Blackman[2] and considered in detail below. In the first place, the nature of immunity itself varies in both the cases. Thus, while acquired immunity plays a large part in protecting animals including human beings from external infection, natural immunity is the most important factor in vegetable life. Secondly, the existence of a circulatory system in animals makes possible the movement of blood to the distant organs, in consequence of which an infection is followed by a general bodily reaction. In plants the lack of such a system is perhaps mainly responsible for the localisation of disease for considerable lengths of time. Again, the existence of this circulatory system in animals has rendered possible the utilisation of serum-therapy technique, whereby immunity acquired at one point is rapidly translocated to different points in the body to control infection. On the other hand, new organs are developing very rapidly in plants and immunity induced artificially at one point cannot be easily transferred to other parts. Even if such a process is conceived of, it is very much inferior to that of animals, and the anti-bodies formed in the older tissues are transmitted only with greatest difficulty to the constantly forming organs. It is obvious, therefore, that serum-therapy cannot be successfully applied to plants. Although this is true to a large extent, more recent investigations by Carbone and Arnaudi,[3] Nobécourt[4] and Chester have made[5] possible the application of vaccination technique in plant protection. In animals, moreover, general bodily reaction is so effective that acquired immunity lasts for considerable length of time, whereas in plants such immunity is not long-standing, and is subject to highly fluctuating external factors such as soil, climate and nutrient supply. Furthermore, while recovery from a disease protects normally an animal from subsequent attacks of the same malady, such recovery in plants does not necessarily immunise them from later invasions of the parasite. Lastly, instances of artificial immunisation of a susceptible plant with a weak or attenuated strain of a known virulent parasite are still rare—a phenomenon which is so successfully applied in the control of animal disease. The recent work of Kunkel[6] indicates the possibility of protecting plants from virus infection such as that of mosaic in tobacco and aucuba by inoculating them with attenuated strains of the infective principle. The effect of these is, however, visible on the plant, such as mottling, etc. Further work is necessary, therefore, to define the conditions of this process.

Nature of disease resistant factors.—The factors that control or modify infection by parasites (including viruses) are mainly two-fold :—(*a*) structural, and (*b*) biochemical. It is futile to separate the two, since the distinction between them is not well defined. It is important, however, to recognise that mechanical or anatomical features play a large part in preventing the parasite from gaining access into the plant tissue, while the physiological condition of the plant determines the establishment of nutritive relations between the host and the parasite. Thus, the plant juice exerts a direct biochemical influence on account of its immediate nutritive value in the early stages of infection. It is possible, therefore, that in some cases, the sap may not be quite suitable for the proper development of a parasite, while in others, the juice may constitute an ideal medium for the vigorous growth and rapid multiplication of the invader. It is sufficient to refer to the work of Zimmermann[7] in this connection. In the process of resisting their entry, plants may exude, by exosmsis. materials which may either hinder or help the regeneration of the disease producing agent. The application of poisonous chemicals externally through dusting and spray treatments is based on the above principle, whereby the poison is made readily available to the organism in the process of feeding on such plants.

Isolation of inhibitory substances.—In Cabbage rot Mallmann and Hemstreet[8] observed a liquefaction and subsequent dissolution of the entire tissue. The extract containing the dissolved material was highly active, even when considerably

diluted, in inhibiting the action of the organism producing soft rot. The lytic principle of the extract resembles bacteriophage in this respect that its potency is not diminished by repeated transference of cultures. It will add greatly to our knowledge if further examination of the same is made. A similar principle was isolated by Wagner from plants infected with pathogenic bacteria.[9] Although this was precipitated by protein precipitants, like ammonium sulphate, its exact nature is still obscure.

Individual chemical compounds in relation to disease resistance.—Cook and Taubenhaus observed early that organic acids and tannins inhibited growth of organisms chiefly fungi (?). In their study on the toxicity of tannins, they showed that the capacity of the host plant to resist the entry of parasites was traceable to the presence of certain chemical substances rather than to structural differences. They assumed that tannins were responsible for this, but discovered that the fungi experimented with did not behave uniformly with tannins: some were more susceptible than others. Furthermore, sodium tannate was found to be less potent than tannin itself. It was therefore suggested that although tannins by themselves may not be chemotactic, their reaction would vary in association with and in presence of other substances occurring in plant cells, a view for which no adequate evidence is yet forthcoming. Subsequently, Cook and Wilson[10] confirmed the above observation in their investigation of the chestnut bark blight disease. Cook and Taubenhaus studied also the toxicity of vegetable acids and oxidising enzymes, in relation to fungi,[11] and showed that the development of root rots is traceable to an oxidase which acts on gallic acid in presence of oxygen to produce a tannin-like substance. This capacity diminishes on ripening, thus rendering the mature fruit more susceptible than the tender one.

Walker and his co-workers were the first to correlate resistance to disease with the occurrence of definite chemical entities. According to them, white variety of onions is highly susceptible to *Colletotrichum circinans* (Bark) which causes onion smudge, while yellow and red varieties are quite resistant.[12] In their subsequent studies they detected the presence of protocatechuic acid, *i.e.*, 3, 4, dihydroxy benzoic acid, in the outer scales of the resistant varieties alone. It was noticed that the concentration of this constituent was high in the resistant types, while it was entirely absent or was present only in traces in the white one.[13] These authors further recognised that the amount of the acid isolated may not represent the total concentration of this component. Moreover, the possibility of other compounds also adding to the resistance capacity has not been overlooked by the authors: but since they have noticed a definite correlation between the quantity of acid detected and the degree of pigmentation, *viz.*, the deeper the colour, the greater the amount of protocatechuic acid present, the above findings are of considerable significance. It may be remarked here that this substance is generally found to occur combined in catechol tannins, resins, gums and anthocyan pigments which are normally present in plants. Therefore it will be of great interest to know whether tannins play a part in disease resistance. In virus diseases of plants, including spike of sandal, no such correlation has so far been established. It is, however, of importance to observe that with the onset of spike, diseased leaves are found to contain more tannins,[14] among which the pyrogallol type is more predominant, while in the healthy or unaffected ones the catechol group of tannins is largely present. In a similar way, the colour of the bark shows distinct change to an intense brown colour as the result of spike infection.[15] To what extent, these factors aggravate or modify the insect attack or the visitations of the carrier of infection, is a problem of fundamental importance in the control of this disease.

Reaction of tissue fluid.—Comes first pointed out that the invasion of plants by fungi and other parasites was dependent on the sugar content and controlled by the acidity of the medium,[16] a greater sugar value and a low acidity of the juice being conducive to the rapid multiplication of the organism. He further observed that to this end, sugar and acids occurred in inverse proportions. Thus, low sugar content was correlated with high acidity and *vice versa*. This provides additional evidence to the observations of Cook[17] that the acidity is a natural defence against parasites. Unfortunately, however, the findings of Comes regarding the relation between sugar content and acidity could not subsequently be substantiated by either Mumford in his studies on curly top of beets[18] or, by the author from his investigations on the spike-disease of sandal.[19, 20] It is pertinent here to remark that increased acidity is a favourable condition for the formation of reducing sugars from disaccharides. Comes' observation of inverse relationship between sugar content and acidity is therefore difficult to explain. It may be that both are important factors and act independently.

Wagner studied the relation of reaction of plant juice to attack by parasites. He infected a number of plants with micro-organisms,[21] and observed an initial rise of 0.1 pH followed by a decrease in pH of nearly 0.6 units. Those plants that recovered from the attack reverted to normal and original acidity, while in those that succumbed, another rise was observed followed by a drop in pH when the tissues died. Harvey

noticed a similar condition.[22] On the other hand, Hurd[23] could not correlate acidity in wheat, with resistance to disease. In sandal spike, the author (*loc. cit.*) observed that with the onset of disease, the reaction of leaf tissue fluid turns slightly more alkaline than that of the corresponding healthy ones but became more acidic with the advance of the disease. No apparent relation could be traced between sandal plants growing with different hosts. It may be concluded that acidity is not an important factor in the resistance of sandal to spike. Mumford examined beets which were susceptible or resistant to curly top. He could not detect any difference in the initial reaction of the juices of the two varieties.[24] Moreover, he found a greater concentration of total sap and of reducing sugars in the susceptible variety. This is however not in agreement with the observations of Carter, according to whom, the beet leaf hopper, *Euttettix tenella* Baker, which transmits this disease does not feed on plants which have a high sap concentration and this was used as an indication of resistance in beets.[25] The present author observed that in the advanced stages of spike a low pH value[19] is accompanied by the exclusive presence of succinic acid and by a characteristic diminution in oxalic acid.[26] Soluble sugars are also present in large quantities. In incipient stages, on the other hand, hydroxy acids are more prominent. These changes would appear to be traceable to the limited availability of calcium consequent on infection. The significance of these observations will be considered elsewhere.[27] Reynolds noticed that the growth of *Fusarium Lini* was depressed in an extract from wilt resistant flax, while in that of a susceptible one, it developed rapidly. The nature of the principle is still undetermined though evidences point to its glucosidic nature.[28]

It is well recognised that wild varieties of different species are more resistant to infection than cultivated ones. The factors involved in this are still obscure. Campbell[29] sought to induce immunity in cultivated applies to *Oïdium farinosum* and to certain insects, through extra-radicate injection of weak solutions of tartaric, citric and malic acids. A similar treatment of sandal with malic acid prior to artificial infection through grafting did not impart any resistance to such plants.

Where acidity could not be correlated with immunity, attempts have been made to explain resistance to disease as being due to buffers occurring in plant saps. Ingold[30] could not, however, establish any relation between immunity and buffer index values in potato. Failure to tracing disease-resisting factors to initial acidity or to buffer values of the juice is due to the fact that these studies have been made on the expressed sap which may not represent the fluid actually present within the cells. Though spike disease induces abnormal changes in the buffering processes of sandal, Srinivasan and Sreenivasaya were unable to trace any striking difference in the buffers of sandal, grown in pots in association with different host plants.[31] It is difficult to reconcile this with Sreenivasa Rau's observation that the host plant associated with sandal determines the composition of the parasite.[32] Obviously factors like age, environmental factors play considerable part in the metabolic activities of sandal.

Enzymes in relation to disease resistance.—Though considerable amount of work has been reported on the enzyme content of plants as affected by disease in plants, no investigation has been conducted in relation to immunity to disease. Recently Suchorukov[33] found that peroxidase action was related to resistance to rust in *Helianthus annus*, *Artemisia* and *Xanthium* being lowest in the immune parts and individuals. On the other hand, catalase and proteoclastic enzymes were not found to play any part in the establishment of immunity. Alteration of the soil acidity affects peroxidase activity in the roots of sunflowers, the greatest depression of activity being observed in neutral soils. The presence of antioxidases or oxidase inhibitors could not be detected. Klotz observed that resistance to diseases was correlated with an inhibitory effect of the bark on certain enzymes produced by the fungi and suggested that similar inhibition of fungous enzymes by plant tissues might explain how certain plants resist the invasion of microorganisms.[34] Since the relation of enzymes to disease resistance has still remained obscure, it will greatly add to our present knowledge if well known resistant types of plants are examined for their biochemical activities as compared with the highly susceptible ones.

Disease susceptibility and nutritional factors.—A large number of cases are known where it has not been possible to trace resistance to definite nutritive factors. On the other hand, striking evidence has been adduced to correlate nutritional deficit with the occurrence of disease. Further, as many plant diseases, particularly those of virus nature, are transmitted in nature through the agency of insects, the factors that determine insect attack should be of more practical importance. Spinks[35] drew attention to the fact that susceptibility to both mildew and rust in wheat as also to mildew in barley was enhanced by the availability of large quantities of nitrogen while application of potash showed a contrary effect. Plants which were semi-starved of nitrogen appeared to exhibit some immunity as also those to which lithium salts were applied. Lead and zinc salts did not appear to confer immunity. He thus established for the first time some

chemical factors which determine susceptibility to disease in plants.

Subsequently Lees showed that water content of plants determines their relative susceptibility to insect pests.[36] According to him, several cases were noticed wherein insect attack was evident due to profuse irrigation or following heavy rainfall, it appears probable, however, that it may actually be a case of physiological drought due to defective soil aeration in spite of such large supply of water. In an earlier publication[37] Lees had shown that water and nitrogen contents were interdependent. A defective root system has invariably been recorded in diseased plants including virus infected ones. It is of great importance to correlate water balance as a factor of resistance to insect attack. Thus, it has been shown by Mumford that a disturbed water content rendered the cotton plant more susceptible to sap feeding insect pests.[24] A similar condition has been observed with sugarcane also: plants suffering from water shortage were found to be more attractive to the attacking thrips than those receiving the normal supply. Recently Mumford has analysed the different factors[38] and has classified them as being due to (*a*) morphological adaptations and (*b*) biochemical factors. The former may include, among others, the formation of thickened epidermis or cuticle or the development of hairs. In the latter case, the action may be due to some condition of the cell sap which will help to repel the invasion of insects or to the presence of substances such as certain essential oils, alkaloids or organic acids or that the composition of the sap may be so altered as to be quite unsuited to insects for their food requirements. The problem is highly complicated that a detailed study is necessary before any definite conclusion can be drawn. Carter has shown that an extremely high sap concentrations in beets are undesirable to and avoided by the sugar beet leaf-hopper, the carrier of curly top of beets, if more suitable food is available in the neighbourhood.[25] Mumford could not observe any marked difference between the varieties which are resistant and those which are susceptible to this disease. Similarly, Srinivasan and Sreenivasaya (*loc. cit.*) could not find any significant changes in the acidity of sandal grown in association with host plants which render the parasite highly susceptible to spike infection. It would appear that in this particular instance, lime is the chief predisposing factor and makes sandal highly prone to the disease since the calcium content of a plant is very high before it manifests symptoms of spike but shows a striking decrease with the onset of disease. Preliminary study on the rôle of lime on the apparent ease with which infection can be artificially transmitted to plants has indicated the harmful effect of this constituent in relation to disease transference.[27] Further evidence is adduced from the observations in diseased localities where application of lime to apparently healthy plants has not minimised the rate of spread of disease in them: in fact, it is significantly high in those cases. This is in conformity with the observation of Laurent[39] according to whom lime renders plants susceptible to diseases.

It will be clear from this short survey that no systematic study appears to have so far been carried out, of the biochemical factors of disease resistance in plants. The only entities that have been considered of any significance by the plant pathologist are the vegetable acids and tannins. Even here our knowledge is inadequate and much more yet remains to be done. It will be of great interest to know how these defensive mechanisms are brought about and the agency responsible for the same. It appears that the respiratory process as measured by the different oxidative activities, such as oxidases, peroxidases and catalase will throw considerable light on the subject. This is particularly so since acids arise also during respiration of the cell and tannins appear to enormously influence their action. Another useful line of inquiry may be directed towards the presence of certain rare minerals which modify the metabolic activities in a strikingly remarkable manner. The biochemical adaptations induced in plants, in consequence, would help to elucidate, many unknown and at present inexplicable phenomena. Certain experiments of a purely preliminary character, carried out by the author, indicated the possibility of employing such elements below their toxic concentration, to immunise plants against plant pathogens. Again, the feasibility of inactivating the causative agent, particularly a virus present in a diseased tissue without destroying the latter by suitable and careful administration of sublethal doses of plant poisons such as copper, arsenic, was tried in the case of spike[27] but could not be pursued further for diverse reasons. Lastly, a study of the mechanism by which certain constituents like water, nitrogen, etc., render plants highly susceptible to infection, will add vastly to our existing knowledge and will indirectly explain the process by which the attacked organism overcomes successfully the marauders of the invader.

A Short Report on the Economic Value of *Artemisia* growing in the North-West Frontier Province.

By N. A. Qazilbash,
Professor of Botany, Islamia College, Peshawar.

ARTEMISIA is very common in the North-West Frontier Province. Successful investigation of the Kurram *Artemisia* for the manufacture of santonin inspired great hopes of finding out additional sources of santonin in other parts of the country, where *Artemisia* resembling very much the Kurram material in appearance, grows in great abundance. It was therefore considered absolutely essential to carry out a thorough examination of the available material in these localities with a view to determining its economic value definitely. On the recommendation of Lt.-Col. E. W. C. Noel, C.I.E., D.S.O., the Director of Agriculture and Allied Departments, North-West Frontier Province, facilities were provided by the local Government for investigating promising regions in Waziristan, Tirah, Khyber and Malakand Agencies. Specimens and samples were collected from different localities at different times. The specimens were studied botanically and the samples were examined chemically for their santonin contents. The results of the findings are briefly mentioned below :—

(i) *Tirah, Khyber and Dir.*—*Artemisia maritima* grows in great abundance in the areas under review. It is very much similar to the santonin-containing *Artemisia* of the Kurram Valley in appearance but differs from it considerably in diagnostic characters. The full details of these characters will appear later. Samples were collected from different localities at intervals of a fortnight. They were examined for their santonin contents. Careful examination showed that the available material in these areas is commercially of no value as it contains no santonin.

(ii) *Waziristan.*—In South Waziristan, *Artemisia* is very abundant in the Wana plains, but the material in question is of no commercial value as it is without santonin.

In North Waziristan, *Artemisia maritima* is found at Datta Khel, Tut Narai, Shirina and Kazi. The areas in question are very small but the plant material growing in these areas contains a very good percentage of santonin. Samples collected during the end of September showed an average of 1·2 per cent. santonin.

(iii) *Chitral.*—*Artemisia* grows very abundantly throughout the country and forms a conspicuous feature of the indigenous flora. There are several species, the principal ones being :—(*a*) *Artemisia sacrorum* ; locally known as "Pispuk". (*b*) *A. scoparia* ; locally known as "Zia". (*c*) *A. laciniata* ; locally known as "Gudraun". (*d*) *A. Thomsoniana* ; locally known as "Daraun". (*e*) *A. maritima* ; locally known as "Maizini Daraun".

The chemical examination of several samples of each of *A. sacrorum*, *A. scoparia*, *A. laciniata* and *A. Thomsoniana* from different regions collected at different times of the growing period, showed that they do not contain any santonin.

Artemisia maritima collected from Drosh and its neighbourhood gave positive results, but the percentage of santonin is very low and is therefore not of much commercial value. It is, however, noteworthy in this connection that the samples submitted to chemical examination were not collected at the time when the plant contains the maximum amount of santonin. If the collections are made at the proper time, the percentage of santonin is very likely to show an increase.

The regions lying beyond Shaghour Valley on the East side could not be visited last year. The question of the economic value of *Artemisia* species growing there could not be taken up for want of time at the disposal of the writer. These regions have ecological conditions suitable for the occurrence of santonin-containing species of *Artemisia* such as *Artemisia brevifolia*, which grows abundantly in Kashmir and which, in certain selected areas, especially shows a good percentage of santonin. It is therefore very much desirable to carry on further investigations in this direction. This might ultimately lead to finding out species of *Artemisia* with a good percentage of santonin and establishing a permanent source of revenue for the Chitral State. A suitable area could then be selected for the cultivation and extension of the most desirable varieties of *Artemisia* for commercial purposes.

Lady Tata Memorial Scholarships.

THE Trustees of the Lady Tata Memorial Fund announce that on the recommendation of the Scientific Advisory Committee they have made the following awards of scholarships and grants for the academic year 1935-36. These awards are open to suitably qualified persons of any nationality for research work in diseases of the blood with special reference to leucæmia. Scholarships: Dr. M. C. G. Israëls (Manchester), Dr. O. Kaalund-Jörgensen (Aarhus). Grants: Prof. W. Büngeler (Danzig), Dr. J. Engelberth-Holm (Copenhagen), Dr. Karl Hinsberg (Berlin), Dr. Ch. Oberling (Paris), Prof. Eugene Opie (New York), Dr. Lucy Wills (London).

"Discovery II" and The Exploration of the Whale's Habitat.

THE Royal Research ship "*Discovery II*" returned from Antarctic on June 3rd after completing her third commission. The expedition was of 20 months' duration and covered 2 arctic summers. The scientific work was in charge of Dr. N. A. Mackintosh with Mr. H. F. P. Herdman as Chief Hydrologist and Lieutenant A. L. Nelson, R.N.R. in executive command.

The ship left Thames on October 21st, 1933, and 5 weeks later (Nov. 21st) was on the whaling grounds of South Georgia. After a few days' stop there, she left Georgia and a line of stations was then made across the Scotia sea to the South Shetlands and from there due north to the western opening of the Straits of Magellan. A number of observations was made with the primary object of following the seasonal changes in the water movements and so trace the circulation of the marine animals and plants, on which the whales and all other antarctic life are ultimately dependent. Thirty full stations were made during the cruise and in addition 19 subsidiary "towing" stations. A full station takes 3 to 4 hours; it includes a sounding and noting of meteorological data; of chief importance are the observations of sea temperatures taken at, at least 20 points between the surface and the bottom—here from 2½ to 3 miles deep—and of the collection of water for chemical analysis from the same points. Concurrently, a series of hauls are made, both vertically and horizontally with nets of varying mesh; those of the finest—200 meshes to the linear inch—are designed to collect the microscopic vegetation, which constitutes the "pastures" of the ocean, and is as important at sea as on land; those of the medium mesh are for the smaller forms of animal life, including young stages of whale food; and the largest, for the adult whale food, a prawn some 2½ in. in length—the so called "krill" which forms the only food of the rorquals. A "towing" station is confined to using certain of the nets to keep a check on the intervals between stations, as the distribution of animal and plant life is sometimes "patchy".

"*Discovery II*" returned to South Georgia on April 10th and on her way back repeated the series of stations already gone through. The second season was begun under winter conditions and after traversing the East Pacific Sector and making some important observations, was back at South Georgia on January 27th, 1935. On her return journey, she communicated with a whale marker "*William Scoresly*" which was also working towards the same objective as "*Discovery II*". While the latter was exploring the whales' habitat and the life-history of its food supply, "*William Scoresly*" is interested in marking the whales in order to know whence and where they travel, at what speed and in what numbers.

"*Discovery II*" is to leave London again in the course of the next autumn on her fourth and probably final commission.—(*From an article in 'Statesman', June 18th.*)

Research Notes.

Can Quantum-Mechanical Description of Physical Reality be considered Complete?

ON the basis of the uncertainty principle arising from Quantum Mechanics, the philosophical outlook of modern science has been asserted to be one of indeterminism and the principle of causality has been repudiated by such scientists as Bohr, Heisenberg, Weyl, Eddington and Jeans. On the other hand Einstein, Planck, Rutherford and Silberstein are staunch adherents to the view that the principle of causality still rules Physical Science. In view of this divergence of opinion, a paper with the above title by Einstein, Podolsky and Rosen (*Phys. Rev.*, 1935, **47**, 777) requires careful consideration. In this paper the authors observe that any physical theory which attempts to explain the objective world must satisfy two conditions, *viz.*, that it must be true and that the description given by the theory should be complete. They formulate the condition of completeness in the following terms: "Every element of the physical reality must have a counterpart in the physical theory." They define a physical reality by postulating that "if, without in any way disturbing a system, we can predict with certainty (*i.e.*, with probability equal to unity) the value of a physical quantity, then there exists an element of physical reality corresponding to this physical quantity." This they consider not as a necessary but only a sufficient criterion of reality. Translating this condition into the language of quantum mechanics they show that in the case of particle with a single degree of freedom its momentum satisfies the condition of reality while its co-ordinate of position does not satisfy that condition. There are now two alternatives: (1) either the description of reality given by quantum mechanics is not complete, or (2) when the operators corresponding to two physical quantities do not commute the two quantities cannot have simultaneous reality. The assumption so far has been that the description given by quantum mechanics is complete so that the second alternative was chosen. The authors now show, however, that this assumption leads

to a contradiction when considered along with the criterion of reality, by proving that two physical quantities with non-commuting operators can have reality. Hence they conclude that the description provided by quantum mechanics is not complete, but express their conviction that some other complete theory is *possible.*

T. S. S.

The Nuclear Spins and Magnetic Moments of the Principal Isotopes of Potassium.

IN the *Physical Review*, 1935, **47**, 739, S. Millman reports the result of his experiments in which the spins and magnetic moments of K_{39} and K_{41} were investigated by the method of magnetic deflection of molecular beams developed by Breit and Rabi. An analysis of the curves led to the value $I=3/2$ for K_{39} and the value of the separation $\Delta\nu$ of the $^2S_{1/2}$ state was thence calculated to be $0 \cdot 0152 \pm 0 \cdot 0006$ cm.$^{-1}$. This result is interesting because it is only recently that the experimental difficulties involved in the measurement of this small separation have been ingeniously overcome by Jackson and Kuhn (*Proc. Roy. Soc.*, A, 1935, **148**, 335), who also obtain a value $\Delta\nu=0 \cdot 0152$ cm.$^{-1}$ They observed the absorption due to a molecular beam moving perpendicular to the direction of observation so that the Doppler broadening was prevented and were thus able to resolve the line. They were unable, however, to fix the value of the nuclear spin definitely, but the work of Millman solves the problem without ambiguity and the magnetic moment of the K_{39} nucleus is then calculated to be 0·39 nuclear magnetons. In the case of K_{41}, it is only concluded that $I > \frac{1}{2}$ and that the ratio of the magnetic moments of K_{41} and K_{39} is such that

$$0 \cdot 42 < \frac{\mu_{K41}}{\mu_{K39}} < 0 \cdot 88.$$

The Structure of Hydrogen Peroxide.

ON the basis of the value for the dipole moment of the molecule, Theilacker [*Zeit. Physikal Chem.*, (B) 1933, **20**, 142] suggested that in hydrogen peroxide there is a free notation of the two OH groups about the O—O bond as the axis. Penney and Sutherland (*J. Chem. Physics*, 1934, **2**, 492) however concluded from wave-mechanical considerations that the two OH groups are not in free rotation, but fixed at an azimuth of 90°. This structure will also agree with the observed moment value. A. Simon and F. Fehér (*Zeit. Electrochem.*, 1935, **41**, 2291) have now studied the Raman spectrum of 99·5 per cent. hydrogen peroxide and find strong evidence for the structure proposed by Penney and Sutherland. Besides a strong line at 877 cm.$^{-1}$(15) due to O—O oscillation, there are two bands at 1462-1345 (1) and 3410-3200 (3). The latter is the well-known water band due to O—H oscillations. The band at 1462-1345 is a deformation band correponding to the 1648 band of water, and shows two clear maxima corresponding to the two kinds of closely allied deformation oscillations to be expected from the wave-mechanical structure. The absence of free rotation is supported by the fact that there is no doubling of the frequencies O—O and O—H.

The Interaction of Atoms and Molecules with Solid Surfaces.

THE activity of atoms and molecules on solid surfaces is an important problem connected with chemical reactions taking place on solid surfaces. The atoms and molecules may vibrate about a mean position or may migrate from one part of the surface to the other, or may be ejected from the surface altogether, by the thermal agitation of the solid surface beneath them. The problem has been investigated by J. E. Lennard-Jones and C. Strachan [*Proc. Roy. Soc.*, (A), Vol. 150, p. 442] who have worked out formulæ for the mean interval between successive excitations from the lowest vibrational state to higher states and also for the mean time during which the atom remains in an excited state. In the following paper, C. Strachan has examined the process of evaporation of absorbed atoms or molecules on a surface.

A Relation between Molecular Spectra and Constituent Electrons.

H. DESLANDRES has traced a very interesting relation between the vibration spectrum of a molecule and its constituent electrons by means of an empirical formula. The formula is given by $\nu=qd_1/r's'$, where ν is the frequency of vibration in wave-numbers, d_1 is an universal constant having the value 1062·5, s' is the number of electrons in the outer ring or rings of the constituent atoms of the molecule, q is an integer and r' is

another integer usually small. His papers in the *Comptes Rendus* (Paris, 1934-35) contain many experimental proofs of his formula.

Adsorption and Catalysis.

THE mechanism of the adsorption of reacting molecules on a surface in relation to catalytic activity is of considerable interest and has been tackled by a number of workers. It is well known that contact catalysis proceeds from strong adsorption which in turn is due to ionisation of atoms or molecules caused by the surface. A hot filament of Tungsten, Iron, Molybdenum or Platinum placed in vapours of Potassium captures the valence electrons and adsorbs the Potassium ions so formed. Nyrop has developed recently (*J. Phy. Chem.*, 1935, **39**, 643) the ionisation mechanism for the catalytic activity of surfaces. He has formulated two postulates for the same: (*a*) The catalytic surface is at the temperature in question, able to ionise such of the molecules among the reactants as are most difficult to ionise; and the surface will cause a strong adsorption, as the ions formed are attracted by the surface. (*b*) Other conditions remaining the same, a molecule with a lower ionisation potential is adsorbed in preference to one with a higher ionisation potential. The ability to cause ionisation can be represented by an electric field at the surface, the potential barrier hindering the free electrons of the metal from escaping. The energies of activation for the adsorption of a given molecule on surfaces will determine the relative catalytic efficiencies of the different substances. The type of ionic adsorption pictured by Nyrop does not involve assumptions regarding "Peaks" on surfaces, formulated by Taylor. When ionic adsorption takes place, the positive ions formed by ionisation weakens the field due to the surface electrons. Catalytic poisons would, according to this theory, consist of those substances whose ionisation potential is low. Catalysts with high ionising power are more easily poisoned than others with lower ionising power. A too narrow potential barrier in relation to the dimensions of the adsorbed molecule may weaken the power of ionisation. When molecules coming into contact with the surface are highly unsaturated, they are adsorbed at two or more points. The preferential adsorption of highly unsaturated molecules is the cause of preferential hydrogenation of unsaturated organic compounds. The above theory developed by Nyrop may be of use in the elucidation of the numerous problems that arise in contact catalysis.

M. P. V.

The "Transition State" Concept in the Interpretation of Reaction Velocities.

ACCORDING to the kinetic theory chemical reactions ought to proceed at extremely high speed, if every collision between the reactants is effective in bringing about a chemical change. The occurrence of numerous chemical reactions which proceed at measurable rates can only be explained by postulating an energy barrier between the initial and final states. The condition of the reacting system at the top of the barrier is designated the transition state. It is well known that the *energy* of the transition state for any reaction can be calculated from the temperature coefficient of the velocity constant. Similarly it should be possible to estimate the *density* of the transition state from the pressure dependence of the specific reaction rate. M. G. Evans and M. Polanyi (*Trans. Far. Soc.*, 1935, **169**, 877) have outlined a general theoretical treatment of the reaction velocities by the transition state method and have applied it to interpret the variations in velocity constants of reactions at high pressures. They are thereby able to account for the exponential dependence of reaction velocity on pressure. They also explain the strong acceleration brought about by pressure in the case of many of the so-called "slow" reactions. It is often surmised that reactions accompanied by a diminution in volume should be accelerated by pressure. The theory detailed in this paper, however, shows that this can only be true if the density of the transition state is intermediate between that of the initial and the final states. The *cis-trans* isomerisation of fumaric acid is not accelerated by pressure though the reaction is accompanied by a diminution in volume. The transition state appears in this case to be one having a lower density than either the initial or the final state. The ideas set forth in this paper, besides their theoretical interest, seem to be of value in the investigation of high pressure reactions of technological importance.

K. S. G. D.

Effect of Cathode Rays on Hydrophobic Sols.

THE literature on the effect of ionizing radiations on colloids is one of conflicting results due to large effects of impurities, sensitiveness to hydrogen-ion concentration and other unknown factors such as internal photo-electric action. May Annets (*J. Phys. Chem.*, 1935, **509**, 39) has investigated the effect of cathode rays on sols of copper, gold, silver, lead, bismuth, platinum, ferric hydroxide and arsenious sulphide. The stability of both positively and negatively charged sols is found to decrease. This is to be expected; the cathode rays on collision with the sols give up their kinetic energy and their charge. With the gain of the charge the stability of the sol will increase or decrease as the sol is negatively or positively charged. The kinetic energy produces ionisation of the dispersion medium and thereby the increase of electrolytic concentration, which in general decreases sol stability irrespective of the sign of the charge. In the absence of a permanent chemical reaction the positive and negative ions recombine with production of heat.

Under cathode ray bombardment the rate of heating of the sol was found to be definitely greater than the rate of heating of water, a phenomenon which is yet to receive an adequate explanation. The accepted heats of flocculation, the energy due to the charge on the surface of the colloid particles and the energy due to the compression of the water around the colloid particles being too small by 10^3, 10^6, 10^{13} times respectively, to account for the observed difference, it is not clear what additional source of energy in the colloid state could account for this phenomenon.

K. S. R.

Starches from Old and New Rice.

THE difference in the physical properties and in the behaviour under various treatments of starch from old and new rice forms the subject of a study by D. L. Sahasrabuddhe and M. M. Kibe and is reported in the *Indian Journal of Agricultural Science*, Vol. V, Part I. Coarse rices, reported to be fit only for bread making as distinguished from the finer ones fit for use as boiled rice, are composed of larger grains, but all are alike in general appearance with the usual characteristic polygonal shape. In one and the same variety, old and new grains show no difference in size. In their behaviour towards methylene blue and iodine, no difference in the starch of different varieties or of different ages was noticeable. Older rices and those of the finer cooking varieties soften more than do new rices and those of the coarser bread varieties, when treated with boiling water and with dilute caustic soda. Likewise as an indication of the extent of digestibility, it is brought out that the hydrolysing action of hydrochloric acid, diastase and pancreatin was more on old rices than on new rices, the same behaviour differentiating also the finer rices from the coarser ones, except in regard to pancreatin. The rices also show significant difference in the amount of liquefaction of the starches on boiling with water, the older liquefying much more than the newer ones and hence being more readily digested. The presence of an amylo-hydrolytic enzyme in the rice grain is established, the prolonged action of which on rice in storage may account for the greater susceptibility of older rices to the various treatments described.

A. K. Y.

Treatment of Opium Habit with Lecithin.

A VERY important contribution towards treatment of opium addiction has been made by Wen-chao-Ma and co-workers at the suggestion of Dr. J. Heng Liu, Chairman of the National Opium Suppression Commission, China. (*F. E. A. T. M.*, Nanking, 1934, Vol. II, 381–387.)

The authors observed that opium smokers can secure comfortable and spontaneous cure by means of lecithin diet. A daily dose of 60–90 gm. of lecithin from Soya bean took from 3 to 6 weeks and sometimes more to break the habit. Soya bean lecithin was found to have advantage over egg yolk preparation in that it is less expensive and is said to be more easily assimilated.

Lecithin does not have the property of directly suppressing the symptom. It has been observed that in serious cases of opium addiction, the amount of lipoid material in the body cell is reduced to nil, while in moderate cases there exists a fair amount and in light cases a relatively big amount. When lecithin is administered orally, the lipoid material is gradually increased with the external manifestation of corresponding subsidence of the craving symptom and an amelioration of the opium habit. The patients treated with lecithin diet had no

disturbance in bowel movement, their appetite was good and they increased in body weight. They enjoyed a sound sleep and felt happy throughout the treatment.

According to the authors, lecithin treatment affords a means of suppressing opium habit without the use of military force or elaborate hospital equipment.

N. C. D.

Transmissibility of Tobacco Mosaic Virus by Aphids.

It being fairly well established that heavy infections with tobacco mosaic in tobacco fields are not attributable to the dissemination of the virus by aphids from tobacco to tobacco, the possibility of transmission by aphid agency of the virus from other host plants is investigated by Isme A. Hoggan (*J. of Agr. Research*, Vol. 49, No. 12). Out of the eighteen hosts tested, transmission was obtained only from the tomato, occasional infections developed in eight and no infection at all from the others. The positive results were however rather insignificant, as only one aphid out of 129 caused infection even in the best of the three species of aphids used as carriers. It is concluded that it is unlikely that any appreciable amount of dissemination of tobacco mosaic is brought about by aphids, except perhaps from the tomato.

The Relation of Plant Characters to Yield in Sorghum.

Correlation studies of eight different plant characters as related to yield of grain per plant in respect of two irrigated and three rain-fed varieties of sorghum, carried out over a series of two seasons in Coimbatore by G. N. Rangaswamy Ayyangar and his assistants, bring out certain characters as reliable indices in selecting for high yield (*The Indian Journal of Agricultural Science*, Vol. V, Part I). The diameter of peduncle, weight, length and thickness of earhead and straw weight have given high positive correlation values. The weight of 100 grains has given high correlation values in the case of the irrigated varieties and low values in the case of the rain-fed varieties. The length of peduncle is either not correlated or is negatively correlated with yield. In the two irrigated varieties, the duration of the crop was also studied and was found to be negatively correlated with yield. A review of the previous work on the subject both in India and outside is also given, the conclusions of the authors being in general agreement with those of the workers in Bombay for all the characters common to both the studies.

A. K. Y.

A Further Note on the Feeding Mechanism of *Chirocephalus diaphanus*.

H. G. Cannon in the above paper (*Proc. Roy. Soc. Lond.*, B, 1935, **806**, 455) describes the feeding mechanism of *Chirocephalus* and largely agrees with the description given for *Anostraca* by Eriksson (*Zool. Bidr. Uppsala*, 1934, Vol. 15, p. 23). There are, however, two important points in which Cannon differs from the latter author and they are (1) the method of production of the oral food current, and (2) the function of the labral gland. According to Eriksson, the current is a continuous stream while Cannon maintains that it is an intermittent one. As regards the labral gland, Eriksson believes that the secretion of the gland agglutinates the extra food matter to be thrown away, while Cannon is of opinion that the glandular secretion is helpful in aiding *Chirocephalus* in binding the food to be eaten. Moreover, the author has been able to show by suitable staining, the existence of an anteriorly-directed food current. With regard to the labral gland secretion he notes that "a part of it oozes round the sides of the labrum and forms a mass underneath the head region and mouth, while a part of the secretion passes backwards beyond the tip of the labrum where it is sucked against the inner surface of the anterior trunk limbs." Here it converts the anteriorly–directed food current into a groove.

Origin and Nature of Nucleolus.

Mary S. Gardiner (*Quart. J. Micro. Sci.*, 1935, **77**, 308) has examined the structure and behaviour of the nucleolus in a number of plants and animals. Using Feulgen's technique, the author has come to the conclusion that the nucleolus is not chromatinic and that it is albuminoid in chemical composition, probably closely allied to "formed yolk". Its significance in regard to secretory activity of the cell is considerable and is by no means an accumulation of waste matter. Its absence in cells where there is

no secretory activity like the oogonia and spermatogonia and spermatocytes of *Limulus* and *Tenebrio* points to a definite correlation between the nucleolus and secretory activity of the cell. And the transformation it undergoes during the process of vitellogenesis when it becomes vacuolated and finally disappears also points to the same conclusion. Cells of most plant tissues are to be considered secretory and the universal presence of a nucleolus in these cells emphasises this idea.

The Autonomic Nervous System of *Amphioxus*.

PROF. J. BOEK'S paper (*Quart. J. Micro. Sci.*, 1935, **77**, 308) describes the enteric nervous system of *Amphioxus lanceolatus*. *Amphioxus* has been often denied a sympathetic nervous system comparable with that of higher vertebrates. The author has, however, found in the walls of the intestine a nerve plexus comparable with the plexus of Auerbach of higher vertebrates and a more delicate nerve plexus analogous to that of Meissner is also reported. The ganglion cells and their synaptic connections with pre- and post-ganglionic nerve fibres all recall the sympathetic system of higher vertebrates. The entire plexus is connected with the central nervous system by visceral nerves and dorsal roots.

Relations of Anorthosite to Granite.

IN connection with the sixteenth International Geological Congress, a very instructive excursion was conducted to the well-known anorthosite areas of Adirondacks and Duluth. A comparison of the rock types from the above areas has been made by F. F. Grout and W. W. Langley (*Journal of Geology*, Vol. XLIII, No. 2). The difference between the two is due to the intense deformation of the Adirondack rocks, during or after crystallisation developing granulation and showing minerals and structures characteristic of metamorphic rocks. At Duluth the rocks have suffered little or no deformation and therefore in common with other anorthosite areas, the granitic phase of the magma seems to have evolved from gabbro magma sometime after the anorthosite was formed. After a very careful study of these rocks both in the field and in the laboratory they have suggested that both the granite and the anorthosite are related to gabbro, but not differentiated directly from each other.

The Vitamin A Content of Certain Sweet Potato Varieties.

VERY marked differences in the Vitamin A content of different varieties of the sweet potato (*Ipomœa batatas*) are disclosed as the result of a study of five varieties commonly grown in Tennessee (*J. of Agr. Research*, Vol. 50, No. 2) by F. L. MacLeod and his students. The differences were of the following order, *viz.*, 13,500 units, 900 units, 1,800 units, 9,000 units and 4,500 units per pound respectively by the varieties Nancy, Hall, Triumph, Southern Queen, Porto Rico and Yellow Jersey. It is also brought out that the Vitamin A content materially increases by the storage of the potatoes for two months or more, the Porto Rico increasing from 9,000 to 29,000 units and the Yellow Jersey from 4,500 to 18,000 units by this process. The observation made in previous work that the Vitamin A content increases with the depth of pigmentation of the varieties is also confirmed.

A. K. Y.

Crystalline Insulin.

BY their new method of crystallisation of insulin hydrochloride from buffer solution, Scott and Fisher (*Biochem. J.* 1935, **29**, 1048) have shown that different samples of insulin hydrochloride having an ash content of 0·02 per cent., crystallised from an ammonium acetate buffer solution by means of zinc, cobalt or cadmium, showed constant values for the respective metals. The average ash content of each insulin salt was proportional to the atomic weight of the metal, and these facts indicate that crystalline insulin contains the metals as chemically combined constituents and not as impurities.

Science Notes.

Two Charophytes from Kolhapur (S. M. C.).—Mr. S. A. Parandekar, Rajaram College, Kolhapur, writes :—Among the flora of Kolhapur two species of Chara have been recently observed and identified as *Chara brachypus.* A. Br. and *Chara corallina* with the help of the key published by Allen (Charophyte Notes from Gonda, U.P., *J. Bombay Nat. Hist. Soc.*, 30, 589). The Charophytes from Kolhapur have not been so far recorded and studied, although about twenty species have been reported from Deccan. The report of the occurrence of the two charophytes might therefore prove of interest.

Chara brachypus A. Br. has been already reported from Bombay (Salsette island) by Dixit (*J. Ind. Bot. Soc.*. 10, 205) and by Allen from Gonda, U.P.

Chara corallina (which is not so abundant here as the other species) has been also recorded from Gonda by Allen, but not by Dixit from Bombay.

I am thankful to Mr. G. O. Allen, and Prof. S. C. Dixit, who have worked on Indian Charophyta, for informing me that Charophytes from Kolhapur have not been so far reported.

Awards of Silver Jubilee Medals.—We have great pleasure in felicitating scientists of India who have been decorated with Silver Jubilee Medals on the occasion of the recent Jubilee Celebration of H. M. the King-Emperor. The list given below is, however, incomplete.

Dr. P. K. Acharya, M.A., Ph.D., D.Litt.; S. P. Agharkar, Esq., M.A., Ph.D., F.L.S.; Rai Sahib Arthaballah Mahant; S. N. Bal, Esq., M.Sc., Ph.D.; Dr. Baini Prashad, D.Sc., F.R.S.E., F.L.S., etc.; D. V. Bal, Esq., L.Ag. (Hons.), A.I.C., F.C.S.; A. C. Banerji, Esq., M.A. (Cantab.), M.Sc.; S. B. Belekar, Esq., M.Sc.; D. Bhattacharji, Esq.; C. C. Calder, Esq., B.Sc., B.Sc. (Agric.), F.L.S.; H. Crookshank, Esq., B.A., B.A.I. (Dub.); J. F. Dastur, Esq., M.Sc., I.A.S.; M. L. De, Esq., M.A., I.E.S.; Deoras, Esq., M.Sc.; Dr. H. B. Dunnicliff, M.A., D.Sc., F.I.C.; Sir L. L. Fermor, O.B.E., A.R.S.M., D.Sc., F.R.S., etc.; Dr. C. S. Fox, D.Sc. (Birm.), M.I.Min.E., F.G.S., etc.; Babu S. K. Ganguli; Rao Sahib S. N. Godbole, M.Sc.; Dr. F. H. Gravely, D.Sc.; Dr. A. M. Heron, D.Sc. (Edin.), F.G.S., F.R.G.S., etc.; Dr. S. L. Hora, D.Sc., F.R.S.E., etc.; Jamaluddin, Esq.; Gurudatta Karwal, Esq.; R. P. Khosla, Esq.; Dr. K. Krishnamurthi, D.Sc.; D. N. Mehta, Esq., B.A. (Oxon.); Dr. E. P. Metcalfe, D.Sc., F.Inst.P.; M. A. Moghe, Esq., M.Sc.; Dr. A. L. Narayan, D.Sc., F.Inst.P.; Dr. B. K. Narayana Rao, B.A., M.B.C.M., M.R.C.S., D.P.H., D.O.; M. Owen, Esq., M.Sc., F.I.P., I.E.S.; G. R. Paranjpe, Esq.; M. W. Sayer, Esq., B.A., Dip. Agri. (Cantab.); D. R. Sethi, Esq., M.A., B.Sc.; Dr. F. J. F. Shaw, D.Sc. (Lond.), A.R.C.S., F.L.S.; Dr. B. K. Singh, M.A. (Cantab.), D.Sc., F.I.C.; Rao Bahadur B. Viswanath, F.I.C.; D. N. Wadia, Esq., M.A., B.Sc., F.G.S., etc.; Dr. T. S. Wheeler, Ph.D., F.I.C., F.Inst.P., M.I.Chem.E.

Origin, Scope and the Present Position of Potato Research at the Agricultural Research Station, Nanjanad.—The potato was introduced into the Nilgiris in the beginning of the nineteenth century. As the climate was quite suitable for its cultivation, it gradually extended and the local ryots (Badagas) finding the crop most remunerative took to its cultivation readily.

The crop now occupies nearly 11,000 acres. The potato is a very delicate crop and the ryots out of ignorance handled the crop carelessly and consequently deterioration set in rapidly.

As the crop is of very appreciable economic importance in the Nilgiris where it forms the main crop raised by the indigenous hill population and as its cultivation was threatened to extinction, the Government of Madras opened a Station in 1917 for the improvement of potatoes and supply of good seeds to the potato growers on the Nilgiris.

The Station is situated in the Nanjanad village and is 10½ miles from Ootacamund on the Governer Shola Road. The soil in the Station is a poor clayey loam and is typical of that to be found on the Nilgiris. It is all dry land. The Station is exposed to the South-West monsoon, the violent winds of which usually damage the potato haulms. The area of the Station is 161 acres and that under cultivation is nearly 45 acres.

The chief crop is potato, but korali and samai are grown in rotation and lupin, a leguminous crop, is grown as a green manure crop. Two crops of potatoes are grown annually the first being planted in March-April and harvested in August-September and the second sown in August-September and harvested in December-January. The bulk of the area is planted to first or main crop in the month of March-April.

Up to 1933, the work on potatoes was carried on in a restricted scale and was confined to the testing of improved varieties of potatoes, method of cultivation and manuring for the purpose.

The Government of Madras approached the Imperial Council of Agricultural Research for a grant for expansion of research work on potatoes chiefly with the object of breeding new varieties. The Imperial Council of Agricultural Research accepted the scheme and sanctioned a grant of Rs. 19,995 spread over a period of 5 years for research work on potatoes.

The work commenced from June 1933. A detailed study of the Botanical characters of all the varieties grown at this Station was made and a list of varieties that produce and retain flowers and those that bear visible pollen have been worked out.

Inter-varietal crosses have been carried out successfully and as many as 7 crosses have been obtained. The seedlings have been raised and are awaiting further study and selection of suitable types for cultivation. It is hoped that some of them may prove better than the existing varieties and a few may be fit for cultivation in the plains as well.

Combing of Good Quality Indian Cottons.—The Publicity Officer, Indian Central Cotton Committee, writes :—There is enough evidence to show that the present-day tendency in the cotton textile industry lies in the increased production of yarns of finer counts. This can be achieved either by using superior quality cottons or by subjecting cotton of a given quality to some such mechanical treatment as will appreciably raise its spinning performance.

Among the latter the most effective method now available is that known as combing. This method consists essentially in the extraction by the combing machine, of a known percentage of the relatively short fibres which are to be found to a greater or less extent in all cottons. The combing process besides serves to parallelise the fibres which results in a greater regularity and higher strength of the yarns. It also serves to reduce such undesirable features as neps from a cotton.

Hitherto the combing process has been almost exclusively restricted to the long staple non-Indian cottons. This restriction is presumably based on the assumption that combing, with its consequent rejection of a large percentage (generally from 15 to 25 per cent.) of the fibres, is economically suitable for such cottons only. In order to examine the limiting performance, as a result of combing, of Indian cottons and to test, among other things, the validity of this assumption, a series of experiments were carried out at the Indian Central Cotton Committee's Technological Laboratory, Bombay. Four Indian cottons of good quality were selected for these experiments. Each cotton was combed to the extent of 20 per cent. and 30 per cent. and spun into appropriate counts of yarn on a ring frame using the ordinary and a high draft system of spinning. The comber wastes extracted from these cottons were respectively mixed with four Indian cottons of suitably low quality, and the mixtures were spun into carded yarns of appropriate counts.

These tests form the subject of a Technological Bulletin (Series A, No. 27) of the Indian Central Cotton Committee. The bulletin comprises five sections and a comprehensive appendix and contains such items of practical interest as a description of the cottons and the machinery used in these tests and full details of treatment accorded to each sample. The results obtained are suitably tabulated and include particulars of fibre-properties, yarn test results, waste percentages, yarn breakages during spinning, and the strength, evenness and neppiness of the yarns spun from the various samples.

The joint authors, Mr. R. P. Richardson, F.T.I., and Dr. Nazir Ahmad, M.Sc., Ph.D., F.Inst.P., discuss the implications of the various results at some length and they offer the chief conclusions drawn from them in the form of a summary.

The work embodied in this bulletin is a valuable contribution to the subject of cotton combing and in its 31 pages will be found much data, of a specific character, which will be of great value to the practical spinner. The bulletin is available to the public at a nominal cost of Re. 1.

* * *

The Mysore Veterinary Medical Association, Bangalore.—The seventh annual conference of the Association was held on 22nd, 23rd and 24th June 1935. Sir K. P. Puttanna Chetty in opening the Conference eulogised the part played by the Veterinarian in the rural economy of the country and stressed on the point that control over the supply of wholesome milk and meat should be handed over to the Veterinary authorities. He hoped that every taluk in the State would soon be provided with a Veterinary dispensary. In referring to Veterinary Research he pointed out the importance of co-operation between the Medical Department and the Veterinary Department as both the Sciences were inter-dependent in matters of experiments on animals and their applicability to human beings. He also referred to the progress shown in the production and preparation of sera and vaccines at the Mysore Serum Institute, which are largely and effectively used both in and outside the State.

Mr. K. Krishnaiengar, Superintendent, Mysore Civil Veterinary Department, welcoming the delegates to the Conference pointed out that the members of the Veterinary profession in Mysore had succeeded in reducing the incidence of cattle disease to the lowest possible minimum by promptly adopting measures of control. He impressed on the members the need for further educating the private owners as well as the public bodies in the hygienic maintenance of live-stock. He further observed that no one was better qualified than the Veterinarian to be in charge of Inspection of milk and meat which are two of the most important foods of human beings. He deplored the apathy of the local bodies on this question as they do not seem to have yet realised the importance of such work.

Major R. W. Simpson in his inaugural address hoped that before long the Veterinary Department would be made an independent unit. Apart from his capacity to treat the sick animals and prevent the spread of contagious diseases the Veterinarian is well qualified to inspect animal food products, to certify for their wholesomeness and purity and thus prevent diseased meat and milk being sold. The Veterinary Surgeon in western countries plays an important rôle in matters relating to public health. He also referred to the live-stock trade which is one of the chief trades in Mysore amounting to a crore of rupees every year and made mention of the good work that is being turned out in the Cattle Breeding Station at Ajjampur, in the matter of improvement of live-stock. He next referred to Poultry Farming and congratulated the Government of Mysore on sanctioning funds for the purpose at Dodballapur and suggested that the breeding of poultry should be taken up in right earnest as it is indeed a profitable and useful concern.

Two resolutions were passed, one for the supply by the Government, of good breeding bulls and buffaloes to village panchayats to improve the breed of the cattle in those parts and the other for awarding a gold medal every year to the member who is adjudged to have done original scientific work.

On the second day twelve papers were read — Important among which were (1) "Local Anæsthesia with Planocaine", (2) "Variola in domestic animals, with special reference to Sheep-pox" and (3) "The Veterinarian's rôle in public health".

The members of the Association visited the Mysore Serum Institute on the 3rd day of the sessions where lectures and demonstrations were held on "The recent advances in the preparation of biological products" and "Epidural Anæsthesia" in animals. In the afternoon the representatives of the General Electric Company demonstrated the uses of the portable "X-Ray" set in animal practice.

The session came to a close after the departmental conference at which important matters

pertaining to the working of the Civil Veterinary Department in Mysore, were discussed.

Lady Tata Memorial Trust.—The Trustees of the Lady Tata Memorial Trust have announced the following Indian Scholarships for the year 1935-36, each of the value of Rs. 150 per month, for scientific investigations having a bearing on the alleviation of human suffering, on the occasion of the fourth anniversary of the death of Lady Tata.

(1) Mr. N. C. Datta, M.Sc., to study the rôle of nutrition and the effect on the body, of mineral contamination of foodstuffs during cooking and storage. (2) Mr. K. N. Gaind, M.Sc., to synthesise new compounds possessing local anæsthetic properties. (3) Mr. M. C. Nath, M.Sc., to carry out chemical and biological analyses of proteins of Indian foodstuffs. (4) Mr. Y. V. Sreenivasa Rau, M.Sc., A.I.I.Sc., to study the proteins of Indian foodstuffs, chemical and biological analyses (at Halle, Germany). (5) Mr. R. Chakrabothy, M.Sc., to investigate nutritional problems of Indian foodstuffs with special reference to Vitamin C. (6) Mr. N. B. Das, B.Sc., for work on the Oxytocic harmone and on oxidation-reduction systems in the body (at Stockholm). (7) Mr. T. N. Ghosh, M.Sc., A.I.I.Sc., for research on the preparation of new anti-malarials. (8) Mr. H. S. Mahal, M.Sc., to work on the anthelmintics, synthesis of substances and examination of Indian plants having anthelmintic properties. (9) Dr. B. K. Nandi, M.Sc., Ph.D., A.I.C., to work on the synthesis of anti-malarials on the line of plasmochin and atebrin types (at Oxford). (10) Mr. H. B. Sreerangachar, M.Sc., A.I.I.Sc., to investigate the growth-promoting and anti-anæmic properties of liver.

The trustees have also made eight international awards for research in diseases of the blood with special reference to leucæmias.

* * *

Pramatha Nath Bose Memorial Medal.—The Council of the Asiatic Society of Bengal has adopted the following regulations regarding the award of the medal:—(1) The Medal shall be awarded every three years at the Ordinary Annual Meeting of the Asiatic Society of Bengal in February. (2) The Medal shall be bestowed on a person, who, in the opinion of the Council, has made conspicuously important contributions to practical or theoretical Geology with special reference to Asia. (3) The General Secretary shall, at a meeting of the Council preceding the Ordinary Meeting in November, place before the meeting the names of at least three Geological experts and three members of the Society for consideration. The Council shall then proceed to appoint an Advisory Board of not less than three members selected from the list placed before them provided that the Council, for special reasons, shall be entitled to select persons outside the list. The Advisory Board shall always include two Geological experts and the General Secretary shall be an *ex-officio* member of the Board. (4) The Advisory Board shall be termed "The Pramatha Nath Bose Memorial Medal Advisory Board." The Board shall appoint a Chairman from amongst its members who shall have a casting vote (in addition to his own vote) in the event of the number of votes being equally divided. (5) The General Secretary shall call a meeting of the Advisory Board on the first convenient date subsequent to the first Monday of December, at the same time requesting members to bring with them to the meeting a detailed statement of the work or attainments of such candidates as they may wish to propose. The General Secretary shall also place before the Board for consideration detailed statements of the work or attainments of any other candidate submitted by any Fellow of the Society. The Board shall make such arrangements as may be necessary for the selection of a name to be submitted to the Council at their December meeting. (6) Notwithstanding anything determined in these Regulations, it shall be within the competence of the Board to abstain from the selection of any name to be submitted for the year and to report accordingly to the Council, in which case, provided the Council concurs, the award for the year shall lapse and shall be postponed to the next following year to be determined in the manner prescribed in the above rules, and, if necessary, deferred again year by year, until an award be made, the period mentioned in Rule 1 in such case to be reckoned from the date of the award.

The University of Madras has conferred the degree of Doctor of Science (D.Sc.) on (1) Mr. A. V. Varadaraja Iyengar, M.Sc., (2) Mr. P. P. Pillai, M.Sc., (3) Mr. C. Sambasiva Rao, M.Sc., and (4) Mr. C. P. Gnanamuthu, M.A. Mr. V. Krishnan, M.A., has received the degree of Doctor of Philosophy (Ph.D.).

* * *

Two Inscriptions from Barakar.—At the ordinary meeting of the Asiatic Society of Bengal, held on the 1st July, Dr. S. N. Chakravarthy read a paper on the two inscriptions which are found on the "right door-jamb of the Ganesha temple in the Begunia group of four temples at Barakar in the Burdwan District". He discussed the previous literature referring to the date of the inscriptions and believes that on palæographical grounds, Śaka 1468 or 1498 should be preferred. The Palæographical evidence was discussed at length and the transcription and translation of the inscription were also given.

* * *

It has been proposed to present Rajasevasaktha Rao Bahadur S. Krishnaswamy Iyengar, M.A., Ph.D., F.A.S.B., formerly Professor of Indian History and Archæology, University of Madras, with a commemoration volume of papers contributed by scholars both in India and abroad, engaged in the field of Indian Historical and Archæological learning and research, on the occasion of his sixty-fifth birthday (15th April 1936). An appeal signed by S. Radhakrishnan, Dr. Surendranath Sen, Dr. P. K. Acharya, Dr. Radha Kumud Mukherjee and a number of others has been issued, calling for donations towards the cost of printing the volume. All communications may be addressed to Mr. C. S. Srinivasachari, M.A., Professor of History, Annamalai University, Annamalainagar, or to Professor V. Rangacharya, M.A., L.T., "Sri Rangadaman," Lloyds Lane, Royapettah, Madras.

* * *

Rao Bahadur K. V. Rangaswamy Iyengar has been appointed Principal of the College of the Benares Hindu University.

Rt. Hon'ble V. S. Sreenivasa Sastri has been appointed Vice-Chancellor of the Annamalai University.

* * *

Rao Bahadur T. S. Venkataraman will represent India at the World Sugar Conference to be held at Brisbane, Queensland, in the last week of August.

It is understood that Dr. (Miss) E. K. Janaki Ammal will attend the Botanical Conference to be held at about the same time in Cambridge.

Dr. Issac, Second Imperial Entomologist, Pusa, will attend the Imperial Entomological Conference in London, after which he will visit the United States, Porto Rico and Hawaii Islands with a view to study the methods of Pest Control in regard to Sugarcane. The problem has acquired importance and urgency in view of the fact that considerable damage is being caused to sugarcane in United Provinces, due to insect pests.

* * *

Sir S. Radhakrishnan left India for Geneva to attend the forthcoming meeting of the International Committee of Intellectual Co-operation on 15th July. The meeting is expected to last for a week. Sir S. Radhakrishnan will visit Oxford, and is expected to return to India in August.

* * *

It is understood that Dr. C. P. Turner, Ph.D., Chairman of the Institute of Technology, Cambridge, Mass. (U.S.A.) has been appointed by the Calcutta University to deliver a course of six lectures on the following subjects relating to "Organisation of Health Education":—underlying principles in health education; construction of curriculum in health education; and school practices of health education.

* * *

Principal P. Seshadri, Rao Bahadur Thakur Chain Singh, Educational Minister, Jodhpur State, Principal A. A. C. Harvey and Principal F. G. Pearce, will constitute the delegation to the World Conference on Education. The Conference will be held at Oxford from August 10th to 17th and Principal P. Seshadri will lead the delegation.

* * *

Professor Brauner, prominent Czecoslovakian chemist, died in February at the age of 80. He was well known for his researches on the periodic system of elements. He was a pupil of Bunsen and Rowe, and by collaborating with Ramsay, Richards, Baxter, Dixon and Mendeleeff, he became a prominent figure in inorganic and analytical chemistry. It was due to him that oxygen was adopted as the basic element in calculating atomic weights. His researches were mainly confined to the rare elements and as a result of his work, beryllium was placed in the second group of the periodic table.

* * *

According to an *Associated Press* message the Government of Travancore are contemplating the starting of a factory for refining china clay and manufacturing porcelain at Kundara, near Quilon. The deposits of china clay at Kumbalom have been found to be of the standard quality. The deposits cover an area of over 30 square miles. It is reported that cheap skilled labour is also available.

* * *

From a report appearing in the *Hindu*, it is understood that proposals are submitted to the Government of Travancore for establishing a separate Fisheries Department instead of its being attached to the Agricultural Department as at present. Canning and cold storage are to be introduced; it is suggested that deep sea fishing should be started and the fish canning should be improved on scientific lines.

The Department now maintains four fishery schools where fisher boys and girls are given elementary schooling and the special fishery school at Karungapalli is making steady progress. Improvement and expansion of the schools, and the establishment of a library, museum and laboratory are also under contemplation.

The State has a fishing population of one and a half lakhs. 95 per cent. of the population eat fish and the foreign trade in fish amounts to 40 lakhs, and a maritime state like Travancore affords an almost untapped source of wealth in fisheries.

* * *

Manurial Research in Travancore.—Among the important manurial experiments which are in progress in the State, mention may be made of (1) the effect of phosphatic, nitrogenous and general manures on paddy cultivation in South Travancore. Superphosphates have given the highest yield; (2) comparison of the values of artificial manures and green manures on paddy; and (3) improvement of alkali soils by the application of special green manures.

* * *

The research work done in India on sugarcane both in its agricultural and manufacturing side since 1932, was reviewed at a recent meeting of the Sugar Committee of the Imperial Council of Agricultural Research. The review shows that the progress made has not kept pace with anticipations and that if the present rate was not accelerated India would not be able to stand on her own legs within the period of protection. The paucity of funds for sugar research and the fact that the Central Research Institute had not been started early enough are the two causes responsible for the slow progress.

* * *

The Terminology of Illumination and Vision. H. M. Stationery Office. Price 6*d.* net.—This paper, of which an up-to-date revised edition is now issued, contains definitions and clear explanations of all the common physical, physiological and ophthalmic terms used in the study of the problems of illumination, the understanding of which is essential to all who wish to follow the rapid progress now being made in their solution.

* * *

Research in Tuberculosis.—It is understood that the Italian Fascist National Federation against Tuberculosis has placed six scholarships at the disposal of the International Union against Tuberculosis of Paris at "Carlo Forlaniani" Institute in Rome for the session from November 15, 1935 to July 15, 1936.

These scholarships are intended for foreign medical practitioners who are already familiar

with tuberculosis problems, and who wish to improve their knowledge in this branch of medicine.

* * *

Occupational Diseases.—Certain occupational diseases, *e.g.*, silicosis, arsenic poisoning, pathological manifestation due to radium and other radioactive substances, epitheliomatous cancer of the skin, will, it is understood, be added to the list of diseases now coming under the convention regarding workmen's compensation for occupational diseases. The most important of these is silicosis, which is associated in other countries with gold mining and with many common industrial processes of which sand-blasting, manufacture of china glass and pottery and stone cutting are examples. Silicosis cannot ordinarily be diagnosed definitely except by well-equipped radiological apparatus, and the Government of India according to an *Associated Press* message have started enquiries regarding the availability of facilities for such tests in the various industrial areas.

* * *

Sir Asutosh Mukherjee Memorial Institute.—The Minister of Education, Bengal, performed the opening ceremony of the Memorial Building on June 29th. The building will not only house the Institute but the Asutosh College founded by him at the beginning of the present century. "It would be a meeting place for people of all nationalities, united by a permanent bond of fellowship based on honourable understanding and determination to advance the best interests of the province and the country."

* * *

Royal Institute of Science, Bombay.—Prof. R. H. Dastur, Head of the Botany Department, has gone on deputation as Plant Physiologist under the Indian Central Cotton Committee, Lyallpur (Punjab).

Mr. G. V. Jadhav of the Chemistry Department has sailed for higher studies in the University of Manchester as one of the Sir Mangaldas Nathubhai Scholars of the Bombay University.

As a result of Scientific Exhibition organised by the Institute in December last in aid of Bombay Hospitals a net sum of Rs. 17,500 has been made over to the Hospitals Fund Committee.

The staff and students of the Institute have collected about Rs. 250 in aid of the Quetta Earthquake Relief Fund.

* * *

The aluminium globe in which Professor Piccard and M. Max Cosyns made their second ascent into the stratosphere three years ago was presented to the South Kensington Museum, London. The actual presentation was performed by M. Jean Willems, who was accompanied by the two scientists.

* * *

Sir E. Shackleton's famous ship, the "*Quest*" will leave shortly for the Arctic carrying an expedition which will explore the area of latitude 70° for geographical purposes. The expedition will be led by Mr. F. L. Wager, who will be accompanied by his wife. The second in command is Mr. Court Aulo, who, four years ago, spent the whole of one winter alone in a remote part of Greenland, snowed up in a small hut.

* * *

Microvivarium.—The microvivarium which, according to Dr. Frank Thore, is the "biological analogue of the Planetarium," is a highly useful instrument for clear and effective instruction in biology and therefore constitutes an indispensable complement to laboratories, museums or botanical and zoological gardens. In a paper appearing in the *Educational Screen*, April 1935, Dr. Georg Roemmert has given an account of this device. The microvivarium exhibit attracted a great deal of attention at the Century of Progress. "In the microvivarium the micro-projection method has been used on a large scale for the first time. This method shows essentially the same things as we otherwise perceive in a microscope. The image is produced from the object itself, by the objective of the microscope with all its colours and movements. The difference is simply that in micro-projection the picture, in huge magnification, appears on a screen, and consequently observation on a microscope is rendered superfluous. The great advantage of this method for popular presentations is that explanations can be given once only for all observers and there is no necessity for unpractised layman to manipulate the microscope. Moreover, objective demonstration in the enormously magnified field of vision, over one yard in diameter, leaves behind an unforgettable impression."

* * *

According to a Calcutta message three earthquake shocks, one of considerable intensity were felt at Siliguri, Bengal, on Thursday, the 4th July. No loss of life or damage to property has been reported. Shocks were also felt at Kalipong and Jalpaiguri in the Dinajpur District.

* * *

The second meeting of the Imperial Sericultural Committee will be held at New Delhi on Wednesday, October 30, 1935. The meeting will consider the progress of the schemes, which have been initiated recently with the aid of the grant given by the Government of India for the purpose and will advise on the allotment of funds available for 1936-37. The schemes started in Bengal, Assam, Madras, Bihar and Orissa and Burma are designed mainly to increase the production of disease-free seed. There are also schemes for investigation of questions connected with silkworm disease.

* * *

Announcement :—

Fifth Congress of the International Society of Sugarcane Technologists (Brisbane, Australia, August, 1935).—The International Society of Sugarcane Technologists is to meet at Brisbane in Australia on the 27th August, 1935. This Society, which generally meets once in three years and alternately in the Eastern and Western hemispheres, has already held four sessions, *viz.*, in Hawaii, Cuba, Java and Puerto Rico. The one at Brisbane is to be the Fifth Congress of this body.

Visits to experiment stations and excursions to factories and sugar plantations have been important adjuncts to the meetings of the Congress. While the actual sessions at Brisbane are to last about a week from 27th August, excursions are to occupy a fortnight after the meeting. We learn that leaders of the Sugar Industry in Australia are to deliver addresses at Brisbane so as to give the delegates to the Congress a true perspective of the special conditions obtaining in the Australian Sugar Industry.

One special feature of the industry in Australia is the employment of White labour alone.

The Congress is to consist of eight different sections representing the various aspects of the Sugar Industry. In the manufacturing section a special feature will be "Sugar boiling with particular reference to the refining quality of raw sugar". Plot technique is to receive attention on the agricultural side; and we learn there is to be a symposium on the very important subject of selection of useful types in sugarcane breeding. Australia is said to be a land of diseases and the Pathological section—including virus diseases and quarantine—is expected to be particularly instructive. Testing of new varieties for disease resistance and control of diseases by cultural operations are two of the rather attractive items in the programme of the Congress.

The Australian Government and the Sugar Industry are doing their best to render a visit to the Congress both comfortable and instructive. In India there are as many as 28 members of this Society representing the various lines of Sugar Research in the country and the Industry in all its aspects. About half a dozen delegates from India are expected to attend the Brisbane Congress.

Academies and Societies.

Indian Academy of Sciences.

June 1935. SECTION A.—C. V. RAMAN: *On Iridescent Shells. Part III.—Body-Colours and Diffusion-Haloes.*—The paper describes a group of interesting optical phenomena which have their origin in the granular and colloidal structure of nacre and have no analogue in the optics of transparent stratified films. S. RAMA SWAMY: *X-ray Analysis of the Structure of Iridescent Shells.*—There is a significant and close correspondence between the results of the X-ray investigation and the diffraction haloes observed by Sir C. V. Raman. The nacreous layers of all the shells consist of aragonite crystals oriented with their C-axes normal to the surface. G. R. PARANJPE AND P. Y. DESHPANDE: *Dielectric Properties of Some Vegetable Oils.*—Castor, olive, sesame and cocoanut oils both in the pure state and in solutions in benzene have been studied. K. NEELAKANTAM, R. H. RAMACHANDRA RAO AND T. R. SESHADRI: *Pigments of Cotton Flowers. Part I.—Cambodia* (Gossypium hirsutum).—The composition of the pigment from the flower petals varies with the variety, locality and with the season. N. B. BHATT: *High Frequency Spectrum of Mercury Vapour.*—In the feeble blue discharge conditions are more favourable for bringing out the spark lines and some higher members of the arc lines both of which are absent in the high excitation spectrum. T. S. WHEELER: *The Electrostatic Potential of a Crystal of the Cuprite type.*—A simple method for the calculation of the potential of cubic crystal lattices has been applied to the calculation of the electrostatic potential of cuprite. R. S. KRISHNAN: *Molecular Clustering in Binary Liquid Mixtures.*—Molecular clusters exist not only at the critical solution temperature but also at temperatures considerably removed from it. S. SASTRY: *On Sums of Powers.* S. CHOWLA: *A Theorem on Sums of Powers with Applications to the Additive Theory of Numbers (III).* K. RANGASWAMI: *The Theory of Normals to a Quadric in Hyperspace.* D. D. KOSAMBI: *Homogeneous Metrics.* B. VENKATESACHAR AND L. SIBAIYA: *Platinum Isotopes and Their Nuclear Spin.*—These results are obtained from an examination of the hyperfine structure of some ten lines in the arc spectrum of platinum.

SECTION B.—N. N. DASTUR, (MISS) R. KARNAD, B. N. SASTRI AND A. VENKATASUBBAN: *Estimation of Urea.*—A simple titrimetric method for the estimation of urea, consisting in the preliminary hydrolysis by urease and subsequent titration of the ammonium carbonate produced by standard alcoholic HCl in presence of acetone, has been described. G. NARASIMHA MURTHY AND V. SUBRAHMANYAN: *Investigations on the Rôle of Organic Matter in Plant Nutrition. Part VII. Economy of Carbon during Decomposition of Cane Molasses in the Swamp Soil.*—A part of the added organic matter passes into the soil sediment and the rest with the supernatant. During the puddling and flooding processes almost the entire quantity of the added organic matter is washed off by the water. S. C. VERMA: *Studies on the Indian Species of the Genus* Echinochasmus, *Part I. and on an Allied New Genus* Episthochasmus.—The presence of a chambered excretory bladder in some Echinostomatid genera is reported for the first time. A new genus *Episthochasmus* is created from a new species of parasitic Echinostomatid from the common dog of Calcutta. The generic diagnosis of the new genus and the new species *E. caninum* is given. G. N. RANGASWAMI AYYANGAR AND KUNHI KRISHNAN NAMBIAR: *Studies in* Dolichos lablab *(Roxb.) and (L.).—The Indian Field and Garden Bean. I.*—The inheritance of the characters of the bean has been studied and reported. B. A. SUNDARA IYENGAR AND V. SUBRAHMANYAN: *Investigations on the Rôle of Organic Matter in Plant Nutrition. Part VIII. Influence of Fermentable Organic Matter on the Transformations of Iron in the Swamp Soil.*—Fairly large quantities of ferrous iron were brought into solution on adding commercial glucose to peaty and laterite soils. The ferrous iron is largely present in combination with the organic acids produced during fermentation. VISHWAMBHAR PURI AND BAHADUR SINGH: *Studies in the Family Amaranthaceæ. I. The Life-History of* Digera arvensis *Forsk.* B. N. SINGH AND K. KUMAR: *The Influence of Partial Pressure of Carbon Dioxide on Photosynthetic Efficiency.*—The nature of the relationship between the supply of carbon dioxide and the rate of assimilation by radish leaves, has been studied. G. S. SIDDAPPA AND V. SUBRAHMANYAN: *Investigations on the Rôle of Organic Matter in Plant Nutrition. Part IX. Oxidation of Organic Matter in the Soil and Plant Assimilation.*—Treatment of soils with minute quantities of chemical oxidisers such as permanganate, hydrogen peroxide or ferric oxide helps to increase the availability of the organic matter of the soil.

Indian Chemical Society.

April 1934. PANCHANAN NEOGI AND (*Late*) GOPAL KRISHNA MUKHERJEE: *A New Method of Preparing Organo-Mercury Compounds of Phenol and Aromatic Amines, Part II.* K. MADHUSUDANAN PANDALAI: *The "Electron Transfer" Theory Applied to the Reactions in the (Photographic) Developing Bath.* MOHAN SINGH: *Studies on Optical Activity and Chemical Constitution. Part I. Optically active Bases and Acids.* P. PARAMESWARAN PILLAY: *On Anacardic Acid, Part I. Anacardic Acid and Tetrahydro-anacardic Acid.* P. PARAMESWARAN PILLAY: *On Anacardic Acid, Part II.—The Construction of Tetrahydro-anacardic Acid.* BASHIR AHMAD, RANCHODJI DAJIBHAI DESAI AND ROBERT FERGUS HUNTER: *The Formation and Stability of Polybromide Derivatives of Heterocyclic Compounds. Part V.—The Bromination of some 1-Aryl-imino-3-aryl-4-keto-5-methyl-tetra-hydrothiazoles and their 5 : 5-dimethyl Homologues and some Remarks on the Theory of Singlet Linkages.* PHULDEO SAHAY VARMA AND K. S. VENKATARAMAN: *Halogenation. Part X.—Preparation of Mixed Halogen Derivatives of Xylenes.* SUSIL KUMAR RAY: *Parachor and Chemical Constitution. Part II.—The Structure of the Triphenylmethane Dyes.* JAGARAJ BEHARI LAL AND SIKHIBUSHAN DUTT: *A Yellow Colouring Matter from the wiid of* Adina cordifolia. *Hook.* JAGARAJ BEHARI LAL AND SIKHIBUSHAN DUTT: *Chemical Examination of* Butea frondosa *Flowers.*—Isolation of a Crystalline Glucoside of Butin. B. K. MENON AND D. H. PEACOCK: *The Rates of Racemisation of Acids of the type R_1 (R_2)-CH. COOH.* K. VENKATA GIRI AND J. G. SHRIKHANDE: *Studies on Salt Activation. Part I.—Influence of Neutral Salts on the Enzyme Hydrolysis of Starch.*

Reviews.

X-RAYS IN THEORY AND EXPERIMENT. By Arthur H. Compton, Ph.D., Sc.D., LL.D., Nobel Laureate and Dr. Samuel K. Allison. (Macmillan & Co., 1935.) Pp. 828. Price 31*s*. 6*d*.

This is the second and revised edition of Prof. Compton's well-known book *X-Rays and Electrons* first published in 1926. The first edition and a revised reprint of the same were soon sold out. The present revised second edition was announced some two or three years ago but as the senior author remarks in the preface "attempts at revision could not keep pace with the rapid growth of the subject". Prof. Dr. Allison who joined in collaboration is a well-known authority on X-rays, and has taken the primary responsibility for the greater part of the present volume, such as X-rays and crystals, dispersion and absorption and X-ray spectra.

The subject-matter is divided into nine chapters, appendix and index, comprising 828 pages. The first chapter gives a wonderfully clear and concise presentation of X-rays and their properties written by Prof. Compton himself, bringing out the advances in the whole field of X-rays which have been treated in detail in the rest of the chapters. The second chapter deals with the production of X-rays from the point of view of different theories and their experimental verification. The third chapter also written by Prof. Compton is divided into four parts and deals with scattering by independent electrons, interference with scattered X-rays, the corpuscular aspects of X-rays and the wave-mechanical theory of X-ray scattering. Dispersion theory applied to X-rays is dealt in chapter IV and the study of crystal structure in chapter V. Diffraction of X-rays from crystals is dealt in two parts from point of view of perfect crystals and second of imperfect crystals. The phenomena of ionisation, fluorescence, magnetic spectra, absorption and ejection of photo-electrons are treated in chapter VII. The next chapter is on the interpretation of X-ray spectra and includes systematisation, relative intensities as well as good discussions on non-diagram lines, absorption edges and chemical effects. The last chapter is devoted to a discussion of accurate methods of X-ray wave-length measurements and their results. It includes discussions on double spectrometer measurements and focussing X-ray spectrographs. There are 11 appendices dealing with subjects like velocity of wave groups, atomic structure factors, electronic structure of elements and discussions of Ewald's reciprocal vectors which have been found very useful in the study of crystals having non-orthogonal axes.

This much-looked-for book is unique in its importance and indispensable to advanced students in general and research workers in particular. It is with great difficulty that the authors have managed to give a presentation which, while it is not loaded with the great amount of matter that had accumulated, is at the same time thoroughly adequate and convincing. Full credit is given to all workers in the field. In the introductory first chapter, for example, results of Bohr's theory on energy levels etc., are taken and the screening constant is put in as a correction due to the repulsion of other electrons wisely avoiding any derivation of these. The authors remark "other methods of calculating these have been proposed by Sommerfeld, Heisenberg, Schrödinger and others. From the standpoint of the assumptions involved, these recent theories are preferable; but the calculations are more complex and the results are very nearly the same as those reached by Bohr. It is probably safe to say that the Bohr theory offers as satisfactory a *picture* of what happens in the atom when radiation is emitted as can at present be supplied". Further in preference to their own earlier photographs, the authors reproduce only the excellent photographs of Du Mond and Kirkpatrick on the scattering from carbon showing the Compton shift and obtained by the use of their multiple crystal spectrograph. In a note the authors remark "among those who have published experiments showing the type of spectrum described above are:" and a list of about thirty original papers are given.

We are happy to note that the work of Indian workers in the field has received adequate recognition.

One does not like to find fault with a book so masterly written. It is, however, difficult to follow figures 1-25 given on p. 29 to illustrate the Bragg law. The interfering beams are shown parallel to each other, one wonders how they could meet and interfere. The get-up of the book is excellent and typing

errors found here and there in first edition are absent in this edition.

B. DASANNACHARYA.

* * *

THE STRUCTURE AND PROPERTIES OF MATTER. By Herman T. Briscœ. (McGraw-Hill Book Company, Inc., New York and London. First Edition, 1935.) Pp. vii+420. Price 21*s.* net.

The book under review is of great interest to those who wish to learn the fundamentals of the Physics and Chemistry of atoms. The author's aim has been to describe the physical concepts concerning the structure of different forms of matter in relation to their chemical properties. In the first three chapters of the book there is a nice historical review of the growth of the atomic concept from the time of the ancient Greek Philosophers to the time of the discovery of Radioactivity. Then follow chapters on Radioactivity, the Electron, Protons, the atomic nucleus, the determination of nuclear charge, structure of crystals, Octet theory, Bohr's theory, distribution of Electrons about the nucleus, valency and lastly, the new Quantum Mechanics. The author's object throughout has been to treat the subject from the view-point of the chemist rather than that of the physicist. It is not, therefore, surprising that the abstruse mathematical steps that are introduced in treatises on the subject have been rigorously avoided, and the final results have been given with their physical and chemical significance. The author has chosen a happy *via media* between a "popular" book and an exhaustive treatise. The chapter on the new Quantum Mechanics gives a very clear account of the recent advances without the introduction of mathematical formulæ, and serves as an excellent introduction to the subject.

The references given in the book are to the standard text-books and treatises on the various aspects of the structure of matter. It should have been much more useful to those who wish to pursue the subject further, if references to the more important original papers had also been incorporated. The Octet theory though mainly of historical interest now, has been given a little too much space. We should have very much welcomed a more detailed treatment of recent topics like Artificial Radioactivity and the Hydrogen Isotope. Almost the whole book is confined to the structure of the atom rather than the molecule. A chapter on the structure of molecules, a subject of supreme interest to Physicists and Chemists alike could have been added with advantage. One feels disappointed to find no mention of Raman Effect and its applications to chemistry.

This book fulfils to a remarkable extent the long-felt need on the part of students of Chemistry of a suitable book which deals with the varied aspects of the structure of matter, not usually available in a single text-book. Though the book is highly useful for the students of the Honours classes, its high price may preclude its use as a text-book.

M. P. V.

* * *

THE DISCOVERY OF SPECIFIC AND LATENT HEATS. By Douglas McKie and Niels H. de V. Heathcote. (Edward Arnold & Co., London, 1935.) Pp. 155 and six plates. Price 6*s.* net.

Nowadays the history of Science is coming to be regarded as important as the history of Kings and Empires and we find that an increasing measure of accurate and painstaking scholarship is being devoted to the subject. The volume before us is a welcome addition to the growing literature on the history of Science and describes an important chapter in the development of Physics. The researches of Black, Irvine and Watt on the one hand and of Krafft, Richmann and Wilcke on the other, are described and their several claims are judiciously appraised. The material has been taken from original sources and the story is told in the investigators' own words as far as possible. Much sympathy and understanding are necessary to penetrate the obscure thought and quaint reasoning employed in the infant stage of the science: the authors have succeeded very well in making these intelligible to the reader. The plates giving portraits of the important personages in this drama enhance the value of the book. Some long current notions are shown to be ill-founded such as the idea that Black designed and used an ice-calorimeter, which is embellished in most text-books by a drawing of the apparatus. We recommend the book warmly to all students of the history of Science.

* * *

"HAND UND JAHRBUCH DER CHEMISCHEN PHYSIK" unter mitwirkung Zahlreicher Fachgenossen Herausgegeben von A. Eucken Göttingen und K. l. Wolf Keil. Band 9.

Abschnitt I. "Atomspektren" von H. Kuhn, Oxford. Mit 78 Figuren im text. (Akademische Verlags-gesellschaft M. B. H., Leipzig, 1934.) Pp. 265. Price R.M. 26.

Atomic Spectra by H. Kuhn of Oxford forms the first part of Volume 9 of the series appearing under the title *Hand and Year Book of Chemical Physics* published with the co-operation of numerous scientific workers and edited by Eucken of Göttingen and Prof. Wolf of Keil. Dr. Kuhn has developed his subject from four main aspects, namely, the empirical foundations of atomic spectra, the theoretical foundations of atomic spectra, the structure and character of various spectra and lastly, the structure of the individual spectral lines themselves. In Section A the author begins with a brief description of the various spectroscopic instruments employed in the study of visible, ultra-violet and X-ray regions and then passes on to the empirical classification of simple spectra. Section B dealing with the theoretical foundations of the problem has been dealt appropriately enough first with Bohr's theory of atomic spectra and then the corresponding wave mechanical theory. Section C dealing with the structure and character of the various spectra has naturally been considered at some length. Even here the treatment is no doubt complete dealing as it does with subjects like multiplet structure, Zeeman effect, Stark effect, periodic table and X-rays and lastly, the many electronic or complex spectra, but one feels that the whole treatment is too brief. Section D deals with the structure of the individual spectral lines and the natural width and other influences on the spectral lines. Here again we are of the opinion that the author has not given the problem of hyperfine structure of spectral lines the importance that it deserves, it being one of the live problems of the day. Finally, we no doubt agree that this is a fitting companion volume to the series forming the *Hand and Year Book of Chemical Physics*. It would certainly have served a more useful purpose if it had only been enlarged and not condensed into such a small volume. The printing and general get-up of the book comes up to the usual high standard set by the German publications.

* * *

AN INTRODUCTION TO THE MODERN THEORY OF VALENCY. By J. C. Speakman. (Messrs. Edward Arnold & Co., London, 1935.) Pp. vii+157. Price 4*s*. 6*d*.

Since the discovery of the electron in 1897 by J. J. Thomson and the nuclear atom by Rutherford in 1911, the developments of the last decade have gradually tended to the general acceptance of the electronic theory of valency and no small part of its triumphs is due to the British School of Scientists. It has united under a single self-consistent viewpoint the three pre-existing partial theories of valency for ionising, non-ionising and molecular compounds.

This modest looking volume by one of the workers in the field gives a lucid exposition of the theory. The essential distinction between electrovalency and covalency, the structure of cyanides and isocyanides, the three electron bond of Pauling and a suggestive chapter on elementary wave mechanics, have been clearly and convincingly presented, the lines along which future advance is to be looked for, being also briefly indicated. The author has taken special pains to suggest a definite system regarding symbolization and terminology of the different types of valencies. A few omissions like that of metallic conduction do not detract from the merit of a book of this introductory character. The treatment is simple, elegant and sufficient and no better introduction can be recommended to one, at present, who wishes to acquaint himself with the modern theory of valency.

B. S. R.

* * *

LA SYNTHESE ASYMETRIQUE. By J. P. Mathieu. (Actualités Scientifiqués et Industrielles, No. 209. Hermann et Cie, Paris, 1935.) Pp. 29. Price 8 Fr.

This is a lucid exposition of the present state of the subject of total or absolute asymmetric synthesis. While partial asymmetric synthesis, that is, synthesis under the directing influence of an already active substance has been achieved in a number of cases, the complete asymmetric synthesis without the influence of any living organism or its product has met with varying amounts of success and failure. The best results have been obtained by using circularly polarised light, and the present monograph recounts in a concise manner the methods and principles involved in the choice of this light energy, and ends with a critical examination of both the positive and the negative results obtained. The monograph will be

found to be highly interesting both to the general reader and the specialist.

M. A. G.

* * *

ELEMENTARY SOLID GEOMETRY. By Naik and Bondale. (Arya Bhushan Press, Poona.) Pp. 214. Price Rs. 2–4–0 net.

The book is well adapted for the use of students of the Intermediate classes. Its main features are a copious collection of examples, a nice and interesting chapter on Preliminary Experimental work and a concise set of postulates. A successful attempt has been made to minimise the number of propositions by appending several results as simple deductions at the end of many of them. The book may appeal to a wider circle of readers if a few chapters on Geometrical Perspective Drawing as taught in the First Year Engineering classes are added.

M. VENKATARAMA IYER.

* * *

DICTIONNAIRE DE LA CHIMIE ET DE SES APPLICATIONS. By Clement Duval, Raymonde Duval, and Roger Dolique. With a Preface by H. Luc. (Hermann & Cie, Paris.) Pp. xxxii + 747. Price 90 Francs.

This important publication is intended only for readers who have an adequate knowledge of the French language. It is not a French–English dictionary dealing with chemical topics.

The 747 pages of this work are packed with information of such an exceedingly useful character as to entitle it to be included in the usual list of books of ready reference. For instance, under cobalt is listed more than 250 of its compounds, each one of them with the appropriate formula. The organic compounds, including those recently investigated, are listed under the appropriate heads and their accepted nomenclature and formulæ are clearly indicated. Being of the nature of an encyclopædia, the material is arranged in alphabetical order which greatly facilitates the task of reference.

The work under review gives not only a list of compounds but indicates at the same time the meaning and significance of the various operations connected with them in the chemical laboratory and industry. It will undoubtedly serve a useful purpose especially in satisfying the immediate needs of workers who are far away from well-equipped libraries.

K. R. K.

VAN NOSTRANDS' CHEMICAL ANNUAL. A handbook of useful data for analytical, manufacturing and investigating chemists, chemical engineers and students. Edited by Prof. John C. Olsen. Seventh Issue, 1935. Pp. xviii + 1029. Price 25*s*.

The seventh issue of this well-known handbook, which has been recently published, will be welcomed by every serious student of Chemistry. Handbooks get rapidly out of date as accurate data accumulate, and therefore need periodic revision. The new edition of the *Chemical Annual* which is being repeatedly improved upon, incorporates a large number of new and useful tables dealing with physical and chemical data and tables giving boiling points, vapour pressures and latent heats of evaporation. The chemical engineers, in particular, will find this handbook invaluable and the well-known author of the "Unit processes and principles of chemical engineering" who has edited this handbook with the help of Dr. B. Whitney Fergusson, as Assistant Editor, and 13 contributors, has spared no pains in bringing out a thoroughly revised and up-to-date handbook.

The publication of handbooks and dictionaries involves a stupendous amount of meticulous care and labour. It is very difficult to review also these publications. Publications which have undergone several editions should be reliable due not only to the fact that they have undergone revision but also because, the chemists, who consult these handbooks, will draw the attention of Editors, in regard to errors in preceding issues and suggest addition of new tables and data. The Editor of *Chemical Annual* has earned the gratitude of a very large community of scientists, who will have numerous occasions to consult the book in the course of their professional work.

A very useful list of the more important books published since 1926 has been included and with the help of the index which serves as a guide to content matter, it is easy enough to locate the pages in which the required data are to be found. The get-up of the book is excellent.

* * *

CHEMISTRY IN COMMERCE. (George Newnes, Ltd., London, 1935.) Vols. III and IV. Pp. 777–1544 + iv. Issued in 16 parts of 1/- each.

The four volumes of *Chemistry in Commerce* which were issued in 32 weekly instalments have recently been completed.

One cannot fail to be struck by the encyclopædic information which the volumes comprise and it can be safely said that we have here, a valuable work, copiously illustrated, at comparatively small cost, which the practising chemist will find numerous occasions to consult.

The subjects dealt with are of varied interest. History, Laboratory devices, analytical control in various industries, etc., are all dealt with by authorities who, by virtue of their intensive works experience, have described in precise terms, with numerous illustrations, the relevant details in simple and eminently understandable language. The chapters on bacteriological research (pp. 1161–1166), Pasteur and fermentation industries (pp. 777-778) make excellent reading. Under Chemistry in Stratosphere (p. 1027), a short account of how Professor Piccard carried a small air-conditioning laboratory into the stratosphere, is described. The chapter on Poison Hazards in Industry (pp. 1430-1435), is invaluable to every chemist. Under Accidental Discoveries in industry (pp. 1158-1160), several instances are described where discoveries were made not entirely by design. "In the field of observation chance only favours those who are prepared" (Pasteur, 1854). "Many men who are very clever—much cleverer than discoverers—never originate anything" (Darwin, 1871). These serve to show how luck enters the field of discoveries. The theme of each chapter has been logically developed. Thus in the chapter on High Speed Centrifuges (pp. 1001-1005), we have first a section on some typical applications, then follows an explanation of centrifugal force and finally a section on the care and maintenance of centrifuges. There are also several notes on the care and maintenance of chemical plant, such as autoclaves (p. 1367) and, on the use of synthetic resins for acid-proofing of chemical plant (p. 1157). Of particular interest are the chapters on measurements of high temperature (p. 1397) and on the use of Parr Bomb calorimeter (pp. 1190-1195). The chemistry and pharmacy of vegetable drugs are dealt with in 14 parts and are systematically treated. The pressure control bottle described on p. 1010, the mechanical shaker prepared from an old bicycle wheel (p. 1042) and the filtering apparatus to maintain constant head described on p. 819 and many other highly useful but simple laboratory devices are to be found throughout the text. The examples mentioned here serve to show the variety of features covered by the book.

One wonders why the manufacture of tea and coffee has escaped the attention of the Editors. On p. 1280, under hydrogenation, molebdinum is spelt as molebdinium. No reference is made to honey under foods. The electrodeposition of lac, a process which has been recently developed (*Chemistry and Industry*, 1934, **26**, 882) has not found a mention in the chapter on lac.

The volumes are, undoubtedly, of the highest interest and we expect that they will gain the popularity which they deserve. Every student of chemistry should learn the ramifications of the subject he is studying and books written in such an easy and understandable manner and still conveying such authoritative information on a large variety of topics, are indeed rare.

* * *

THE CARBOHYDRATES. By E. F. Armstrong and K. F. Armstrong. (Longmans, Green & Co., London, 1934.) Pp. vii+252. Price 15*s*.

During the last quarter of a century Armstrongs' monograph "The carbohydrates and glucosides," has been an indispensable volume in the library of every one interested in the chemistry of sugars. The growth of knowledge in this important field of chemistry necessitated the separation of the glucosides, and a separate monograph entitled "Glycosides" by E. F. Armstrong and K. F. Armstrong, appeared in 1931. The publication under review completes the work of revision and the two companion volumes constitute a masterly exposition of a highly intricate subject.

The volume was eagerly awaited for some years past, notably as a result of the great advances on the structural aspects of the carbohydrates due to the work of Professor Haworth and his school at Birmingham. The volume has been thoroughly revised retaining the main features of treatment, which have proved so popular. Thus, attention is confined to natural sugars and their derivatives; glucose is taken as a typical sugar and its properties and reactions considered with particular reference to its biochemical transformations.

Since Fisher's discovery (1893) of the isomeric derivatives of glucose α and β, an enormous volume of work has accumulated on the structure of glucose. Tollen's butylene oxide ring structure was accepted by Fisher.

The discovery of yet a third reactive form, the so-called γ-form by Fisher and Irvine, needed some revision. The remarkable success which attended the work of Haworth, on the structure of the glucose rings, by the well-known methylation method, resulted in giving the amylene oxide structure (1926) to the oxide form of glucose. Conclusive proof has now been adduced to show that the α and β forms are represented by the 1 : 5 Gluco-pyranose structure and the γ-form by the 1 : 4 gluco-furanose structure. The book under review gives a masterly exposition of the structural aspects of the chemistry of sugars.

The present edition dealing with recent work which has resulted in giving some degree of certainty on matters of structure where controversy existed before, will be welcomed by all.

This brief note cannot be concluded without paying a tribute to the authors of the excellent volume. It is very sad to reflect that the demise of the junior author has removed from the field a bright and promising young scientist, thus resulting in an irreparable loss.

* * *

TEXT-BOOK OF BIOLOGY. By E. R. Spratt and A. V. Spratt. (University Tutorial Press Ltd., London.) Price 9*s*. 6*d*.

The study of biology has become more and more a matter of public interest. The Panama canal was as much a victory over the mosquito and those two diseases, yellow fever and malaria, as a feat of engineering skill. The medical student begins his study with a course in biology and medicine is becoming more a question of applied biology and less a mere study of disease. Biological knowledge is found to be more and more indispensable in agriculture and various industries. Civilised society finds biological knowledge to be of great economic and cultural importance. The recognition of the value of biology has led to its being introduced in schools and colleges. Educationists feel that no subject in the school curriculum, except the mother tongue, is of as great a value as biology. And with the introduction of the subject in schools, there has come up a crop of books on biology. Some are of the old general biology type. Some are merely botany and zoology text-books stitched under the same cover. A few, however, are fresh in their treatment, emphasising the point of view of biology, that something is characteristic of *all* living things and that this something is achieved in many different ways. The book under review takes after the traditional method. Function should receive greater emphasis. On this foundation the study of structure should be based. And animal-life and plant-life should form the two dovetailing pieces of one subject. The common forms usually found in books on general biology are dealt with in the greater part of the book. There are some chapters on the physiology of plants and animals. Some account of the ecology of plants and animals is given. A chapter on heredity, variation and evolution is also included. The book may be of use to students who take up biology in the Intermediate Colleges and to medical students.

* * *

BOTANY PRINCIPLES AND PROBLEMS. By E. W. Sinnott. (McGraw-Hill Book Co., Inc., New York and London.) Third Edition, 1935, pp. xix+525, Price 21*s*. net.

This is a valuable addition to the list of books on Botany for use in Colleges. The book may be divided into two parts. The first few chapters of the earlier part deal with the introductory survey, the history of botany, the cell, the morphology and physiology of the various organs of the plant like the root, leaf and stem. The next two chapters deal with the physiology of metabolism and growth. Then comes an useful and interesting chapter on "Development and Morphogenesis" followed by two chapters on certain aspects of ecology. The special chapters on "Heredity and Variation" and "Plant Evolution" not only provide refreshing changes from the commonly used text-books packed with morphological details but also serve to widen the scope and horizon of the beginner in botany and bring before him the interesting and useful aspects of the subject. A really good book not only catalogues facts but also arouses the interest and curiosity of the student.

In the second part of the book the various groups of the plant kingdom are discussed with the help of a few specific types. It is interesting to note that the vascular plants as a whole have been called Tracheophyta and divided into three broad groups, the Lycopsida, Sphenopsida and Pteropsida. A chapter on primitive vascular plants—Psilophytales has also been rightly included and placed at the beginning of the Tracheophyta. The author opines that the seed-bearing

habit is not the monopoly of the Gymnosperms and Angiosperms which comprised the old group—Spermatophyta. Consequently this term has been discarded altogether.

Reading through the book one however gets an impression that the treatment in the second part of the book has been somewhat rapid. The systematic botany of the Angiosperms may well have been dealt with in greater details and a few families discussed. The Charophyta are better kept as a separate group instead of being wedged in between the Chlorophyceæ and Phæophyceæ; and the number of genera in the Charophyta is certainly not restricted to two as stated on page 379.

The author has within the space at his disposal dealt with the various aspects of botany. The language is clear and direct while the profuse illustrations and excellent get-up of the book leave nothing to be desired. Another valuable feature of this book is the questionnaire at the end of each chapter which not only helps the student to test how much he has assimilated but also helps him to think and to develop gradually the "inquisitive and critical attitude".

A. R. R.

* * *

LES PROBLEMES DE LA RADIOGEOLOGIE. By W. Vernadsky. (Hermann et Cie, Paris, 1935.) 66 pages. Price 15 francs.

This brochure forms number 201 of the series, "Actualités Scientifiques et Industrielles", the geological section of which is published under the direction of M. Lucien Cayeux. The book is based mainly on two lectures delivered by the author at the University of Paris in 1933. In the earlier pages, the author gives a brief résumé of the outstanding contributions to the subject of radio-geology by scientists like Curie, Joly and Strutt. This is followed by a classification of the scope of the subject. The remaining portion of the work is devoted to a discussion of the special problems pertaining to radiogeology, such as the determination of the oldest portions of the earth's crust, calculation of the age of sedimentary rocks, Joly's thermal cycles, thermal heterogeneity of the biosphere, the low temperatures of the ocean, petroliferous beds as fields of radio-chemical phenomena, the migration of uranium lead, the radio-chemical alteration of radio-active minerals, the carbonaceous minerals (tucholite group) discovered in ancient pegmatites, the chemistry of the oldest portions of the earth and the planetary exhalation of helium.

The bibliography is printed in very small type and this is probably the reason for the many typographical errors found in it. The International Table of Radioactive Elements forms a useful appendix to this excellent summary of the subject of radiogeology.

C. S. P.

* * *

INTRODUCTION TO GEOLOGY. By Prof. E. B. Branson and Prof. W. A. Tarr. (McGraw-Hill Book Co., Ltd., New York and London.) Pp. viii+470. 21s. net.

"Introduction to Geology" by Profs. Branson and Tarr forms a useful addition to many of the excellent text-books on the subject which have been published in English. In this book the authors have aimed to present the fundamental principles of Geology in a style simple enough to meet the needs of elementary students who require but an intelligent initiation into a study of the subject.

The book is divided into two parts. Part I deals with physical Geology. Starting with an account of the mode of formation of igneous rocks and their constituent minerals, the processes of weathering and rock decay are described followed by the next four chapters on the earth sculpture as brought about by various denuding agencies. Chapters IX and X deal with sedimentary and metamorphic rocks, and are succeeded by two more chapters on the action of snow, ice and wind. The next three chapters XIII to XV give some account of the structural and dynamical geology, the last one being devoted to earthquakes. Part II deals with historical Geology. A concise statement of the views on the origin of the Earth is followed by a narration of the conditions which existed during different geological periods. Descriptions of the plant and animal fossils of the several formations are given and in addition the economic products found in them are also noted. Chapter XX of this part gives an account of the origin, distribution and methods of locating petroleum.

In spite of the limited scope of treatment of the subject one would have liked to see some account of the coral reefs and the importance of corals as rock builders, included in the book. The presentation of the fundamental principles of any branch of science in a simplified style divested with

much of technical phraseology is no simple matter and unless considerable care is exercised in the selections of suitable terms, loose expressions are likely to creep in which would lead to a misconception of statements. The book under review is not entirely free from a few such faults. The terms lava and magma as used by the authors would have been the better for a clearer definition. At the great depths, mentioned by the authors in page 212, pressure is likely to induce rock flowage and not granulation as stated therein.

Substitution of "conjunction" for "connection" in line 37, p. 211; "does" for "is" in line 9, p. 212; "becomes" for "became" in line 6 (reading from the bottom p. 222) would perhaps make the sense clearer.

The phenomena of re-fusion, density stratification of magmas and igneous intrusions by magmatic stoping are still too controversial to be presented to elementary students as well-established facts.

Despite these few slips, the authors have succeeded in achieving their main purpose, and the book will certainly prove to be a welcome addition and appeal to those readers, who require an elementary knowledge of Geology. It is profusely illustrated with well-chosen photographs and drawings and the general get-up of the volume is all that could be desired.

B. R. R.

* * *

THE WORKING, HEAT TREATING AND WELDING OF STEEL. By H. L. Campbell. (Messrs. Chapman & Hall, Ltd., London.) Pp. 185. Price 11*s*. 6*d*.

The above book is a welcome addition to the large number of treatises already available on the subject of Steel Metallurgy, and should serve as an introduction to the study of different aspects of Steel Metallurgy. It is not usual to find in one book references to the manufacturing processes as well as the shaping, treating and testing of different classes of steel. It is from this point of view that the text-book should be recommended not only to students and apprentices who desire to take up the profession of iron and steel manufacture but also to Managers of industrial establishments who desire to have a general knowledge of all phases of Steel Metallurgy.

The first 3 chapters dealing with various methods of manufacturing steel and the basis on which the steels are classified give all information that is necessary in as brief and intelligible a manner as possible for making a beginning of the study. The author's reference to the High Frequency Furnace shows that all the latest developments in the field of steel making have been kept in view. The physical tests of steel which may perhaps have been dealt with later, deal with only the important tests on the basis of which the qualities of different steels are compared.

The effects of temperature changes and mechanical working of steel form a proper prelude to the next chapter giving a very brief account of different kinds of working steel. The development of steel products from ingots, and the equipment for the manufacture of important classes of steel products such as rails, sections, plates, tubes and axles are brought out very clearly without going into great details which would surely confuse the beginner. Cold rolling which has been playing so prominent a part in the production of quality steel products is given its due importance.

The brief description of the physical constituents of steel with suitable microphotographs of the important constituents in steel is necessary for proper understanding of the heat treatment of steel which plays so important a part in the utilisation of the best qualities that are available in steels; and the equipment required for a proper sized heat treatment shop should serve as a valuable guide to the Engineering or Metallurgical student during his first years of apprenticeship.

Only one chapter for alloy steels and their heat treatment seems rather too brief, considering the varieties of alloy steels in common use and their growing importance in all fields of engineering activities. Even in a small text-book such as the one under review one would like to have more information and data about stainless steels, high speed steels and spring steels.

The extensive use of welding in the construction of engineering structures, automobiles, rail-road cars, etc., fully justifies a detailed description of the principle of welding and the different processes which are in vogue. The concluding chapter describing the various processes adopted for the preservation of steel forms a fit ending for this admirable, though brief, text-book. One should have no hesitation in stating that this book should find a prominent place on the tables of all students of engineering and metallurgy.

A reference to the bibliography on the metallurgy of steel given at the end of the book may not be out of place. From a perusal of the list, one is satisfied that he can get any information, however detailed, relating to the practice of steel making, rolling of different steel products, the treatment of different classes of steel, standards accepted for the various classes of steel, and micrographic study of the constituents of steel. One would have, however, liked to see in this list several valuable contributions from well-known Metallurgists on the Continent and in England.

The laboratory assignments given at the end emphasise the scope of the book, namely, its use as a text-book by technical students.

D. V. KRISHNA RAO.

* * *

COFFEE IN 1931 AND 1932.—Economic and Technical Aspects. (International Institute of Agriculture, Rome.) Pp. 229.

This monograph, published under the auspices of the International Institute of Agriculture, Rome, is the first of the series of monographs on important agricultural subjects which the Institute proposes to publish.

A considerable portion of the monograph is devoted to the economics of coffee production, and over-production, no doubt due to the severe depression the coffee trade is struggling under ever since 1929. Over-production seems to be not so much a result of better yields as of increased acreage under coffee. The phenomenon of over-production is possibly only a temporary one, fostered by the boom years prior to 1929, and, therefore, may be expected to be checked by the lean years that have followed since then. Over-production is not, however, the only problem that faces the coffee grower. Other problems of various and varied interest like soil exhaustion, control of insect pests and fungoid diseases, improvement in quality, improved methods of marketing are all becoming increasingly important and clamour for solution.

These and allied problems form the subject-matter of the latter parts of the monograph. An exhaustive review of work on technical and ecological aspects of coffee growing forms an interesting and instructive chapter to both planters and students alike for study and assimilation. Equally of interest is the chapter on diseases and pests of coffee.

The monograph gains value by the inclusion of a short but instructive chapter on the preparation of coffee in its various stages. This attempt is specially welcome in view of the numerous attempts that are being made all the world over to improve the quality of the berry before it comes into the market. That quantity must give place to quality cannot be too often stressed and it is therefore of particular satisfaction that a monograph on coffee should include and emphasise this point for thoughtful consideration.

The value of the monograph as a reference book, which it is intended to be, is enhanced by the inclusion at the end of each chapter of a fairly exhaustive bibliography of the period which it covers.

The book deals with the years 1931 and 1932, a period during which the depression in the coffee trade first began to be felt seriously. The situation has not improved with the passage of time and with the prices at the level that they are gives little hope of improvement in the near future. It is therefore of obvious importance that a pause should be made in the field of competitive production—nay, over-production—and a stock of the situation taken. The book under review does this in an eminently practical manner and more, adds technical information towards a solution of the various problems that beset both the coffee grower and the trader alike. The book may be consulted with advantage not only by the planter but also by the scientist.

* * *

INDUSTRIAL POSSIBILITIES OF SOME RESEARCH WORK DONE IN INDIA. By Gilbert J. Fowler, D.SC., F.I.C. (Society of Biological Chemists, India, 1934.) Pp. 42. Price Re. 1.

This neat little publication contains the substance of two lectures delivered by the author at Bangalore under the auspices of the Society. It is very welcome just now, when two Research Organisations have recently been established, one by the Government of India and the other by the Government of Mysore for co-ordinating Industrial Research being pursued at different centres at present.

The first part of the brochure deals with "Researches resulting in permanent factories," particular mention being made of The Sandalwood Oil Factory, Mysore, The Whitelead Syndicate, Bangalore, The Government Soap Factory, Bangalore and the Turpentine Distilleries at Clutterbuckganj

and Jallo. Next part dealing with problems which have been investigated and the results of which await commercial exploitation is of greater interest. Manufacture of Glue as a Cottage Industry and as a subsidiary industry in Tanneries is well worth serious consideration by all interested in a self-sufficient India. Utilization of Molasses is the problem of the day, in view of the large number of Sugar Factories (152) recently started and manufacture of cheap power alcohol should become an accomplished fact very soon; actually, the Mysore Sugar Co., Mandya, have already started the manufacture of cheap alcohol from molasses. The section dealing with small industries requiring very little capital is the most important in the opinion of the reviewer, as the starting of such industries is the only possible means of improving the economic condition of the masses.

By drawing attention to a large number of problems of economic importance to India, Dr. Fowler has done a distinct service to the cause of economic reconstruction in this country. One only hopes that the trouble he has taken will to a small extent at least be repaid by organised research on the new problems and accumulation of useful and practical data.

A very adequate bibliography enhances the usefulness of this important brochure considerably.

K. A. N. R.

* * *

REPORT ON THE SALT INDUSTRY OF RAICHUR AND GULBARGA DISTRICTS. By S. R. Bhate, B.A., B.Sc., with notes by L. S. Krishnamurthy, B.Sc., and Captain L. Munn, O.B.E., M.E. (Bulletin No. 11, Department of Commerce and Industries, H. E. H. the Nizam's Government; Industrial Laboratory.) Pp. 154. Price Rs. 2-8-0.

The publication under review discusses in detail all the sources of salt in Hyderabad which may be classed under the two heads: (1) Salt earth and (2) Saline water. The quality of salt at present manufactured as a cottage industry has been investigated by the analysis of a large number of samples from different localities and useful and necessary data have been accumulated.

The relative merits of pan evaporation and stack evaporation of brine have been investigated and as a result of these investigations the author arrives at the very interesting conclusion that "the advantage of stack evaporation (10′ cube) over solar pan evaporation (10′ square) is 22·5 times". It is therefore suggested that stack evaporation should be adopted and would be a distinct aid to this cottage industry. But one might sound a note of caution that more work is probably necessary before this point could be definitely settled.

The Government Industrial Laboratory, Hyderabad, is doing a distinct service to Indian Industry by publishing reports of the investigations conducted there, but, without any intention of striking a discordant note, it may legitimately be asked whether a price of Rs. 2-8-0 for such publications is not far too high in a country like India where the purchasing power of educated classes is so small.

K. A. N. R.

Forthcoming Event.

IMPERIAL COUNCIL OF AGRICULTURAL RESEARCH.

September 2nd to 4th, 1935—Meeting of the Governing Council.

111835.—Printed at The Bangalore Press, Bangalore City, by T. Subramania Aiyar, Superintendent, and Published by B. N. Sastri, M.Sc., A.I.C., A.I.I.Sc., for the "Current Science" Board of Editors, Indian Institute of Science, Hebbal Post, Bangalore.

Current Science

Vol. IV] AUGUST 1935 [No. 2

CONTENTS.

The Problem of Malnutrition in India.

THE fact that millions—perhaps the majority—of the people of India suffer from various degrees of malnutrition seems beyond dispute. It is true that more precise data on this question are required—data which can be collected only by dietary surveys, and the systematic physical examination of sections of the population to reveal the incidence of states of malnutrition and deficiency diseases. But sufficient information already exists to prove that malnutrition is widespread. If the diets of the majority of the population, particularly of the poorer classes, are compared, even in a rough qualitative way, with the dietary standards put forward by modern physiologists, it at once becomes apparent that the former fall short of adequacy; in general, they are deficient in the more valuable proteins, and in certain vitamins and mineral salts. Again, food deficiency diseases—beri-beri, certain forms of anæmia, epidemic dropsy, xerophthalmia, etc.—are common throughout most of India. The poor physique and lack of resistance to infection shown by the majority of the population in many parts of the country also suggest that the average Indian diet is a defective one.

It should be realised that this state of affairs is not peculiar to India; that, in fact, the same problem exists in most countries of the world. Outside Western and Central Europe, North America, Australia and New Zealand, and perhaps a few other fortunate countries, the diet of the mass of the population is not very different in quality from that of the poorer classes in India. Thirty or forty years ago, malnutrition and certain food deficiency diseases—*e.g.*, rickets—were very common in England; it is only gradually that the dietary level of the masses is being raised even in the most prosperous countries. To-day China presents a problem of malnutrition which is as formidable as that of India, and there is evidence that other Eastern countries, such as Java, Malaya, and Japan, are in a scarcely more favourable position. The question of malnutrition in South America has been little studied as yet, but quite recently the authorities of one South American country very

remote from India—Chile—have reached the conclusion that dietary deficiency is one of the main causes of ill-health and disease in that country, and are taking steps to investigate and remedy the situation. It may well be that, for a number of reasons connected with religion and climate, the problem of dietary deficiency in India is more difficult of attack than elsewhere, but the difference is one of degree, not of kind. While economists talk of over-production of foodstuffs, the greater part of the world's population would be the better for more food of superior quality to eat.

As regards India itself, the subject of nutrition may conveniently be considered under two heads: research, and the practical application of modern knowledge. More precise data about the dietary habits of the people in different parts of the country are required; these can be obtained only by laborious surveys. In conjunction with such surveys, systematic physical examinations of selected groups should be carried out; apart from general impressions, we have little exact information about the prevalence of states of malnutrition and deficiency disease among urban and rural populations. It would be useful (and simple) to collect in schools data about average height and weight, for each age group, in different races, classes, etc., throughout the various provinces; English and American growth standards are not applicable to India. There are wide gaps in our knowledge of the nutritive values of Indian foodstuffs, particularly as regards vitamins, and mineral salts; steps are already being taken to fill these gaps. Quite apart from such obvious and necessary investigations, there remains a great deal of original clinical and laboratory research to be done on food deficiency disease. In all probability, there are food deficiency diseases in India which have never been observed or described, and even those diseases which are familiar text-book entities might repay further clinical, pathological and epidemiological study.

Certain statistical investigations concerning food supply in relation to population would help to clarify the situation. First a dietary standard reasonably capable of fulfilling the needs of human beings should be chosen, and this diet translated into terms of foodstuffs which can be produced or made easily available in India. Secondly, the food requirements of the population in terms of this adequate diet can be calculated, and a comparison drawn between the national requirements so defined and existing agricultural production and food imports. The fact would probably emerge that existing food production and import fall far short of the point at which such a diet could be supplied. Lastly, the improvements and changes on agriculture and imports necessary to attain this end can be stated in exact figures and subjected to careful analyses. A series of calculations of this nature would provide a solid basis for agricultural (and even fiscal) policy. The resulting figures might not, indeed, be too hopeful; they might clearly show that, in the absence of potentialities for great increase in food production, or of increase in national wealth allowing for food importation on a large scale, there must be a growing disproportion between available food supply and the dietary requirements of an expanding population.

A broad survey of the type outlined may be impossible at the moment owing to the lack of sufficiently accurate data about food values, crop production, livestock, etc. But there is no reason why such information could not be obtained. Bowley and Robertson, in their recent report,[1] have described the defects of existing statistical services and made various suggestions for their reorganisation. Improvement in statistical information would help nutrition research workers to grasp the problem of malnutrition in India as a whole.

Let us turn to the question of practical application, to what may be termed public health nutrition work. Sir Robert McCarrison has repeatedly emphasised the fact that knowledge in this field has already far out-run any efforts towards making use of that knowledge for the benefit of the people of India. Difficulties are enormous. While poverty is the main obstacle, ignorance and prejudice, by no means confined (in India as elsewhere) to the classes which are too poor to have much choice in the matter of food, must play a great part in producing malnutrition. Again, public health nutrition work in India can only develop *pari passu* with public health work of other kinds. But steps could be taken to ensure that nutrition work is given a prominent position in existing public health programmes, and that as time goes on it should receive increasing attention.

---

1 A Scheme for an Economic Census of India. New Delhi, 1934.

For this purpose it is essential that emphasis should be laid on nutrition in the training of public health workers of all kinds, including medical officers of health, nurses, health visitors, etc. In some Western countries much practical nutrition work is carried out through the medium of maternity and child welfare centres, health visitors, and the school medical services. As such activities develop in India, opportunities will arise for improving diet by educational and other means.

The question of attaching nutrition specialists to public health departments might receive consideration. Each provincial department might perhaps employ an official with an extensive knowledge of the subject whose duties would be to prepare educational material, to assist in maternity and child welfare work and work in schools, to lecture to medical students, nurses, and subordinate public health officials, to regulate diet in public and residential institutions, etc. All large public health departments in U. S. A. have workers of this kind attached to them. It might be difficult to find men or women qualified to undertake duties of this nature at present in India, but in future provision could be made for their training by various means.

Elementary instruction about diet and food values might be given to the higher grades in the schools, both public and private. The interest taken in McCarrison's book *Food*, and the considerable use that has been made of it in schools, suggest a willingness on the part of school teachers to add this subject to the curriculum. But teachers themselves must first be taught its importance, and a useful line of attack would be through teachers' training colleges. With regard to the education of the public, something might be accomplished by means of suitable press articles, wireless talks, etc. There seems to be an awakening interest in nutrition throughout the country, and the literate classes might respond to intelligently prepared propaganda.

The problem of malnutrition in the village might be approached by selecting small "demonstration" rural areas for intensive work. Data about dietary habits could be collected by careful surveys involving a number of families, and subsequently correlated with the "state of nutrition" of the population group concerned. The exact nature of the deficiencies in the diet would thus be made apparent. The next step would be to attempt to improve nutrition in the "demonstration" area by various means—education and propaganda, maternity and child welfare work, improvement in livestock and agricultural production, etc. The chief aim of a public health nutrition experiment of the type outlined would be to investigate the possibilities of improvement lying within the resources of the people themselves. Results obtained in small areas might have a general application throughout the country.

If the public health side of nutrition work is to develop in the right direction, it is essential that adequately equipped research institutions should exist to provide basic knowledge. Nutrition research is being actively carried on at Coonoor and elsewhere, but there is room for extension of existing institutions working in this field and for the creation of new ones. Sir Robert McCarrison, writing in *Current Science* in July 1932, suggested that "each Presidency or Province should have its own Institute for the study of Nutrition". The activities of the ideal nutrition research institute should include basic scientific research, systematic surveys of foodstuffs, study of cheap well-balanced diets within the means of the poorer classes, field and epidemiological investigations, and a good deal of propaganda and education work. It should have a department for training public health workers of various kinds.

Researches in animal husbandry, nutrition, agriculture, and human nutrition, and efforts to apply in practice the results of scientific research in these fields, are complementary and directed towards the same end. The greatest possible co-operation between those concerned in these activities is desirable.

W. R. AYKROYD.

Planned Prosperity for the Peasant.*

SIR GEORGE SCHUSTER was one of the few Finance Ministers of India who took a comprehensive view of Indian finance and studied it in its larger relation to Indian economic life. Hence his interest in Economic Planning and Economic Councils, which he sought to prepare by inviting to India, two experts to report on the collection of economic statistics in India. In the stimulating lecture he recently delivered before the Royal Society of Arts, Sir George believes, as all those must who have given the problem any serious attention unaffected by prepossessions of one kind or other,—that "the vast masses of the Indian population must be based on rural economy and no conceivable degree of industrialisation can alter this within any period that can be foreseen". It is, therefore, of vital importance to the prosperity of the country that Indian agriculture should take advantage of recent developments in mechanisation of agriculture. But the increasing product of agriculture that will follow must find a sale abroad, but sales abroad are only possible if India will buy industrial goods in return, and a serious obstacle arises in the form of India's own industrial ambitions. If India will not buy from abroad, she cannot sell abroad, and if she cannot sell, her rural population is doomed to continued poverty. The dilemma is resolved, and the interests of a prosperous agriculture with the growth of Indian industrialisation are reconciled by the argument that "there are certain more elaborate forms of industrial products for which the Indian market alone will not give an economic foundation for independent manufacture, and for which India will not, for a long time to come, have the necessary skilled labour and technique"; among such are "motor-cars, telephones, wireless machines, gramaphones, etc." The category exists, though the list may be questioned. India can proceed along her own industrial advance in the direction of production of cotton piece-goods, iron and steel manufactures, sugar, and so on. Thus Sir George Schuster rests Indian prosperity upon the tripod of improved agriculture, increased industrialisation, and imports of goods that India cannot expect to produce for herself in the near future on anything like an economic basis.

People are too often inclined to judge a country's prosperity by reference to figures of production and trade alone, and are either indifferent to problems that affect the standard of the life of the poor or are openly impatient of proposals like Factory and Social Legislation that are calculated to transfer to the workers some share of the gains in production. Sir George is emphatic in his view that "there is a great need for policies which will increase the material wealth of India, but this will be valueless unless they also secure the proper distribution of that wealth, and the greatest need of all is to raise the standard of living of the masses of the people". The problem is how to bring about a higher standard of life, and "somehow or other to get the rural masses of India out of the rut of their present low standards". This can be done partly by Government action and partly, as Sir George Schuster says, by convincing "public opinion of the need and getting all those who have any influence in the villages—landlords, District Councils, Municipalities, Universities, etc.—to work upon it. Mass psychology needs to be moved in the matter."

In view of the recent repudiation of economic planning by the present Finance Minister, it is of much significance that Sir George Schuster reaffirms his faith in economic planning. He holds that "some foresight" is necessary "as to what is to be produced, and an intensive effort to maintain production and presentation for marketing at the highest level of efficiency, so as to produce the best quality at the cheapest price." He believes that "Governments and especially the Government of a country like India, must take thought and give the lead and impetus in these matters". The first duty of the Government, in the absence of "sufficient statistical records" and their interpretation and co-ordination, is to arrange for "a map of its own economic country", and for this purpose a Central Organisation of Economic Intelligence and Statistics must be created. If an intelligent public opinion is to be created, "knowledge must be disseminated". In the light of this emphatic reaffirmation of the need for a scientific and ordered basis of study of economic data for the development of the

* "Indian Economic Life: Past Trends and Future Prospects", by Sir George Schuster: Sir George Birdwood Memorial Lecture, Royal Society of Arts.

country, it is to be hoped that the Government of India will take early steps to give effect to the recommendations of the experts and arrange for an Economic Census of India at an early date, even if the Economic Advisory Organisation recommended by Sir Arthur Salter is to wait till the new Constitution is in operation.

The Baluchistan Earthquake of May 31, 1935.*

By W. D. West,
Geological Survey of India.

THE earthquake which occurred in Baluchistan on May 31st was remarkable in two respects. It was of high intensity at the epicentre, causing great mortality and much damage to property, yet it was felt over a comparatively small area, a little over 100,000 square miles. This is a rather characteristic feature of earthquakes in Baluchistan, and indicates that they must have a shallow focus. The epicentre, where the greatest damage was sustained, extended from the north-west of Quetta to half-way between Mastung and Kalat. Its position is shown on the accompanying map, together with the epicentres of the earthquakes of 1931 and 1909.

Since most of the inhabitants were asleep at the time of the earthquake, little information was forthcoming regarding the beginning of the shock. It so happened, however, that night operations were being carried out that night at a place about 4 miles to the north of Quetta, and it appears from the evidence of those taking part that about 5 to 10 seconds before the main shock started there was a preliminary tremor sufficiently strong to be recognised as an earthquake shock. The main shock came from the south and was accompanied by a noise like the roar of a train in a tunnel. The motion was described by the same observers as being like the action of a small boat in a choppy sea. People in Quetta itself generally described it as a sharp horizontal shake.

The shocks seem to have lasted nearly half a minute. During this time the whole of Quetta City, part of the Civil Lines, the Railway Quarters, the Police Lines and the R. A. F. Lines were laid in ruins. The northern and north-eastern part of Quetta, in which are situated the Cantonment and the Staff College, was much less affected; and although the city must have suffered a shock of almost intensity 10 on the Rossi-Forel Scale, at the Staff College, distant only 3½ miles from the city, the intensity was only 6. In fact, many people living in the Staff College area went back to bed after the earthquake, and were surprised the next morning when, on going towards the city to do their shopping, they found the whole place in ruins. This was almost certainly due to the varying nature of the ground, the area where destruction was greatest being situated on water-logged alluvium, while the Cantonment and the Staff College are situated on dry alluvium.

One striking feature of the earthquake, which caused many people to think that it had a volcanic origin, was the great quantity of dust which arose from the surrounding hills, and specially from Chiltan mountain, both at the time of the main shock and also on the afternoon of June 2nd, when a very severe aftershock occurred. Needless to say the "smoke," which was thought to have been seen ascending from Chiltan, was only dust caused by the collapse of thousands of tons of limestone as a result of the severe shaking which the mountain received.

Another feature of the earthquake which aroused much interest was a line of fissuring in the ground which extended on and off for over 70 miles, from the south side of Chiltan to near Kalat. In places along this line the alluvium was severely fissured, in other places the ground had subsided two or three feet on one side or the other, while elsewhere the ground had heaved up a foot or two. Careful examination of this area, however, showed that the fissuring was purely a surface phenomenon, coinciding with the line of greatest intensity of shock, and it was clear that it did not penetrate the solid rock beneath. Where this line of fissuring crossed the railway line from Quetta to Nushki, the rails were severely crumpled.

* Published with the permission of the Director, Geological Survey of India.

About 100 miles south of Quetta an old mud volcano burst into eruption at the time of the shock, and continued ejecting hot mud for about 9 hours. The term 'mud volcano' is really a misnomer, since it is generally accepted that these phenomena have no connection with true volcanic activity.

In discussing the origin of the earthquake, it is necessary to take into consideration the geological structure of Baluchistan. The general alignment of the mountains is shown very well on the accompanying map, and since the geology and geography are very closely related, in that the axes of the rock folds are parallel to the main mountain ranges, the map also gives an idea of the general geological structure of the country. These folds have been formed by a compression of the rocks in a N. W.—S. E. direction, so that, taking the area as a whole, the folds should be aligned in a N. E.—S. W. direction. This, however, is not the case, and instead the mountains are looped up

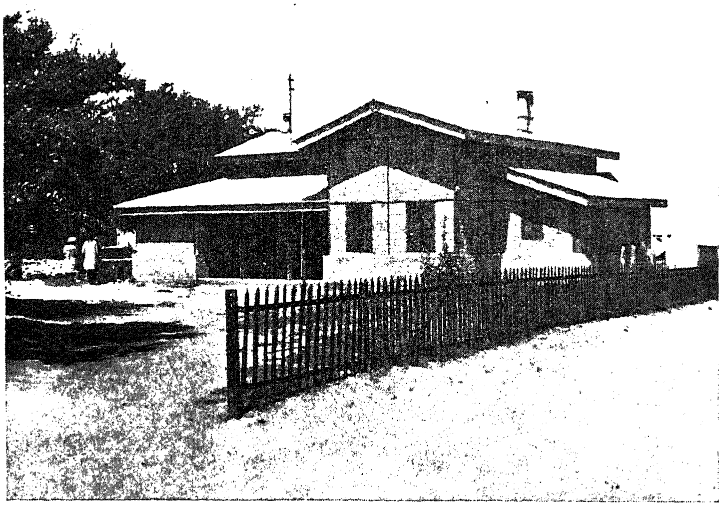

Fig. 1.
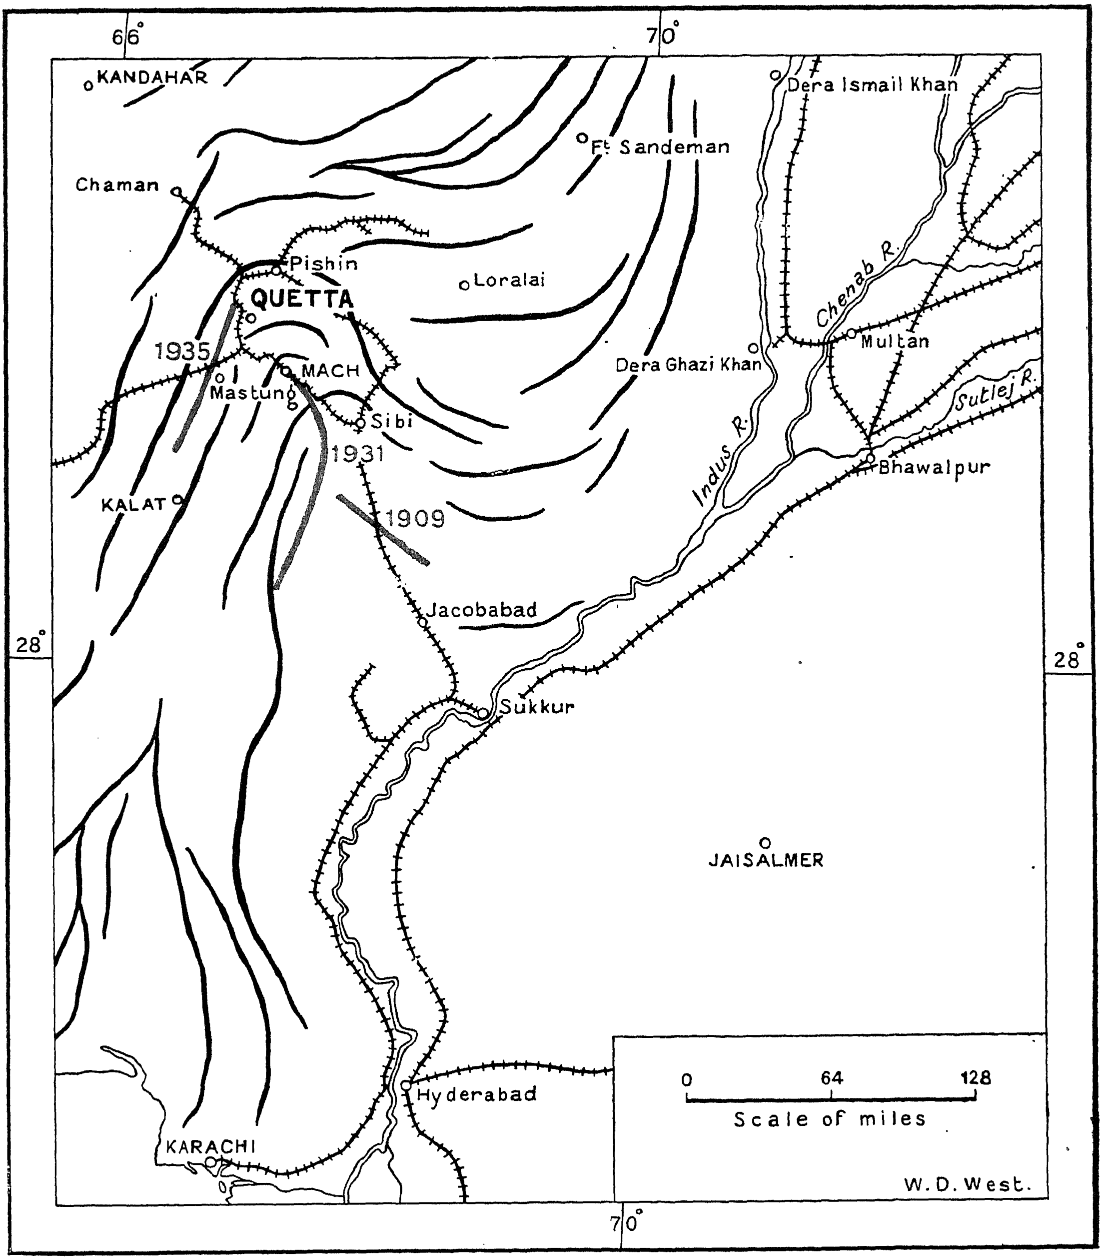
An earthquake-proof bungalow built by the North-Western Railway.

Fig. 2.
The Dak Bungalow, Quetta.

to the north-west between Jacobabad and Quetta. Now it is generally accepted that these folds have been formed by the movement of the old stable mass of Central Asia towards the stable mass of Peninsular India, resulting in the compression of the soft marine rocks in between to form the mountains. It is therefore suggested that this sharp deflection in the alignment has been caused by some underground obstacle



MAP OF BALUCHISTAN AND SIND, SHOWING THE ALIGNMENT OF THE MOUNTAINS AND THE EPICENTRES OF THE LAST THREE EARTHQUAKES.

which is obscured from view by the alluvium of the Indus valley, and which has prevented the free movement of the folds towards the south-east. The effect may be likened to the waves of the sea, when they are deflected in their course towards the shore by the obstruction of a breakwater. The waves flow freely on either side, but are held up by the break-water. Whether or not this hypothesis is correct, it is a fact that the geology around Quetta is more complicated than it is in any other part of Baluchistan, and the rocks have yielded here not only by folding but also by fracture. It is around this re-entrant angle that the greatest strain must occur, and it is here that one would expect most earthquakes to originate. In actual fact this is the case, and most of the severe earthquakes which have visited Baluchistan have been confined to an area within a radius of about 150 miles of Mastung.

In the case of the last three severe earthquakes which have visited Baluchistan, namely those of 1909, 1931 and 1935, the epicentres of which are shown on the map, no connection could be traced between the location of the epicentres and any known fault. It therefore seems clear that the earthquake, if it was due to movement along a fault, must have been connected with some fault which does not reach the surface of the ground.

The enormous death roll which occurred at Quetta is directly attributable to the very poor manner in which nearly all the buildings were constructed. Owing to the scanty rainfall in this part of India, it has been the practice in the past to use a mud mortar. Such a mortar has very little bonding power, and when an earthquake occurs, the very heavy lateral force to which the building is subjected simply causes the bricks to slide over one another, and the building collapses. In the case of the present earthquake a feature of great interest was provided by certain North-Western Railway bungalows which had been built since the 1931 earthquake and had been designed on earthquake-proof lines. Although surrounded by smashed buildings, they are without a single crack. The accompanying photographs show the completely ruined Dak bungalow in Lytton Road and one of the new earthquake-proof Railway bungalows situated on the other side of the road. It is difficult to imagine a more striking illustration of the efficacy of sound earthquake-proof construction, in which rigidity has been the main consideration. By making a building as rigid as possible, instead of the building falling apart during an earthquake, due to the different parts of the building behaving differently, it will move as a whole and so avoid being cracked. That these Railway bungalows did move as a whole was clearly shown by the fact that those who were living in them were so severely shaken that they were unable to stand up inside the bungalow during the earthquake, while heavy almirahs were also thrown down. These bungalows had been made rigid by bracing with vertical and horizontal iron rails, and had been constructed to withstand a horizontal acceleration of 3·2 feet per second per second. From this, however, it is not to be inferred that the acceleration of the earthquake motion was less than 3·2 feet per second per second, because in constructional work a considerable factor of safety is always allowed, which may be as much as 3 or 4.

It will be seen from the map that the centre of earthquake activity has gradually moved north-westwards since 1909. It is doubtful, however, if any conclusion regarding the location of the next earthquake can be inferred from this. Such knowledge as we have of previous earthquakes, in Baluchistan shows that they jump about from place to place in accordance with no apparent law. If, however, an earthquake be regarded as affording relief to the strains which have accumulated in the rocks, then it may be fairly safely predicted that the next earthquake, when it occurs, will not be located along the same line as the present one.

The Pre-Vindhyan Geology of Rajputana.

By A. M. Heron,
*Geological Survey of India.**

SINCE 1907 a geological survey of Rajputana and the States of Bombay which adjoin it to the south in Gujarat has been in progress. Its results have been presented from time to time in papers by the author and his colleagues Mr. C. S. Middlemiss, Dr. A. L. Coulson and Mr. B. C. Gupta, and several other publications are in preparation. As, however, it may be some time before the main description dealing with the work done in central Rajputana since the Great War can appear, it has been thought advisable to submit a brief sketch of the results obtained. A somewhat fuller account of this has appeared in the *Transactions of the National Institute of Sciences of India*, Vol. I, No. 2.

The rocks below the Vindhyans and the Malani volcanics have been arranged in four groups, separated by three erosion unconformities, all of which are in places clearly shown by basement conglomerates accompanied by other evidences of discordance, and are in addition well displayed in the mapping by the trend of the boundaries of the formations. The unconformity most distinctly seen, that at the base of the Delhi system, has been traced for something like five hundred miles along the edges of the synclinorium, which is almost exactly coincident with the limits of the Delhi system, for outside of it representatives of the Delhis are insignificant and somewhat uncertain. It appears to have been the successor to a geosyncline in which the Delhis were accumulated; on either side of it are found the older formations—the Raialo series, the Aravalli system and the pre-Aravalli gneisses.

The succession is shown in the annexed table.

In view of the presence in Rajputana of four distinct Precambrian and Archæan formations, separated by important unconformities each denoting a period of diastrophism and erosion, and of the immense thicknesses of strata involved, it is reasonable to infer that the Bundelkhand gneiss and the banded gneissic complex at the base of this long sequence are among the oldest rocks which occur anywhere upon the earth's surface. If the Vindhyans are also placed in the Precambrian, neglecting the doubtful evidence of obscure markings which are held by some palæontologists to be primitive Cambridge brachiopods and by others to be vegetable remains, the sequence is still further lengthened and the oldest rocks are pushed farther down in the Archæan.

Unfortunately we can say nothing definite regarding the relationship of the banded gneissic complex and the Bundelkhand gneiss, as their mutual junction is everywhere concealed by a broad syncline of Aravallis resting on both of them unconformably. In a recent paper in *Current Science*[1] by Mr. W. D. West, it is stated that they are thought to be equivalent. This, however, is the case only in the sense that both are overlain unconformably by the Aravallis, for they are entirely different lithologically. The Bundelkhand gneiss is a true granite, unfoliated except in its extreme western extension, non-porphyritic, and remarkably uniform over all its wide area of outcrop; it is traversed by intrusive dykes of dolerite and great reefs of quartz. The banded gneissic complex, on the other hand, was originally a sedimentary formation, predominantly argillaceous, but showing by two anticlinal inliers of massive bedded quartzites that its oldest visible strata were arenaceous. Over most of its extent, however, especially in the south, its sedimentary character has been obscured by the intrusion of multitudes of acid and basic rocks in great variety of texture and of different ages, giving rise to a complex of banded and foliated gneisses. In the north the banded character is on the whole less strongly marked and the intrusions are more in the form of large bosses of a dark porphyritic biotitic granite, usually strongly foliated, with its cognate pegmatite and aplite veins forming composite gneisses, and masses of basic rocks.

To the north-west of the synclinorium a third type of gneiss, a fine-grained and usually homogeneous granite, is present at

the edge of the Marwar plain, but is much obscured by the Erinpura granite intrusive in it, and by alluvium. It is clearly older than the Delhis but the Aravallis have not been seen in association with it.

The Aravalli system consists predominantly of an immense but immeasurable thickness of phyllites, in certain zones of which impure limestones and fine-grained quartzites occur. Its base is marked by a thin grit resting on the underlying gneisses, and in two widely separated areas thick basic amygdaloids and pyroclastics have been accumulated near the base, in one case passing up into a great series of conglomerates, and these again into massive quartzites.

A feature of great interest is the occurrence, south of Chitor in south-eastern Mewar, of a tract in which the Aravallis have undergone hardly any metamorphism, being still shales with low rolling dips. As they are followed across the strike from east to west, in the direction of the ancient belt of mountain-folding and igneous intrusion of the synclinorium, dips steepen and they become successively slates, phyllites and ultimately mica-schists with small garnets, magnetite, staurolite, chiastolite and kyanite. The intruded dolerite becomes epidiorite and hornblende-schist.

At the top of the little-altered Aravallis are several quartzite and grit formations, of very limited extent and somewhat obscure relationships, to which have been given local names. Some of them (the Badesar quartzites, the Kanoj and Khardeola grits) appear to be slightly unconformable upon the Aravallis; others, the Ranthambhor quartzites, which are found in eastern Jaipur as well as in south-eastern Mewar, are conformable with the Aravallis.

The suggestion is made that the Gwaliors may also be unaltered Aravallis, like those just mentioned, which, like them, have escaped metamorphism owing to their distance from the protaxis of diastrophism now represented by the Aravalli range and by the protection of the solid mass of Bundelkhand gneiss upon which they rest.

Intrusive igneous rocks in the Aravallis are scarcer than in the pre-Aravalli gneisses and in the Delhi system. In the unaltered Aravallis they comprise the dolerite mentioned above, which may perhaps be the hypabyssal equivalent of the Khairmalia amygdaloid at the base of the Khardeola grits, and in the metamorphosed Aravallis to the west they are granite and ultra-basic rocks. The granite, acid, fine-grained and almost devoid of mica, forms several bosses near Udaipur City; on their margins intrusive relations with the Aravalli limestones are excellently shown, and the granite, by *lit-par-lit* injection of the mica-schists, gives rise to a broad band of composite gneiss which runs south-east from Udaipur City[2] for many miles. The ultra-basics are talc-serpentine-chlorite rocks occurring near Rakhab Deo[3] and at other places. The post-Delhi Erinpura granite also invades the Aravallis south-east of Salumbar.

The Raialo series is the thinnest and simplest of the four formations discussed, consisting of a thin, occasionally conglomeratic quartzite at the base, which, however, is more often than not missing, then about two thousand feet of white crystalline limestone, with at the top of the sequence but exposed in one area only, in the core of the syncline (see below) near Kankroli, an unknown thickness of garnetiferous biotite-schist.

A correlation has been made between the widely separated exposures of massive white crystalline limestone which are believed to belong to this series, near Raialo on the frontier between Jaipur and Alwar States, a great syncline running out from below the base of the Delhis past Nathdwara and Kankroli and extending as long narrow synclinal outliers beyond Bhilwara to the Jahazpur and Sawar hills near Deoli, the celebrated Makrana marble in Jodhpur State, with other outcrops along the strike to the south-west and, in the south-eastern Mewar area of unaltered Aravallis, the "Bhagwanpura limestone". In the Makrana and other occurrences to the north-west of the Delhi synclinorium the limestone is a calcium carbonate rock, in those to the south-east of the synclinorium it is dolomite.

The limestone is very free from igneous intrusions, only a few dykes of the post-Delhi pegmatite penetrating it, but the garnetiferous biotite-schists which overlie it give excellent examples of how various types of gneiss arise from the injection of one original rock. Starting from biotite-schist intruded by large definite dykes of pegmatite, these may become so numerous that they crowd into each other leaving little schist, or they may take the form of

---

[2] *Mem. Geol. Surv. India*, 1934, **65**, pt. 2, 152-153.

[3] *Rec. Geol. Surv. India*, 1933, **65**, pt. 4, 453.

clusters of sills, ending in the schist being intimately and uniformly permeated by multitudinous interfoliar veins, forming a banded composite gneiss often highly contorted. There is no evidence that the Raialos were invaded by any igneous rocks of post-Raialo but pre-Delhi age.

The rocks of the Delhi system are exposed in a great synclinorium which extends throughout Rajputana from north-east to south-west, disappearing beneath the Indo-Gangetic alluvium at the one end at Delhi, and under the alluvium of the Gujarat plain at the other, in Idar State. The north-western flank of the synclinorium is a straight line but its south-eastern side is a great curve; in the medial portion of this, for about forty miles along its length, the synclinorium is a simple syncline about six miles wide but to north and south of this it widens greatly by the development of numerous isoclinal folds.

In the southern portion the base of the Delhi system is exposed as a simple curve without re-entrants, as the present surface of erosion cuts only the higher portions of the folds and therefore the upper formations only, in the synclinorium itself. In the northern portion, however, the basal beds are repeated in great curves running athwart the general direction of the axes of folding, the anticlines pitching to the north-east. We find that the uppermost divisions of the Delhi sequence are more fully preserved in the southern part of the synclinorium than in the northern.

South-west of Ajmer the synclinorium consists of two synclines of Delhis separated by a tongue of the pre-Aravalli banded gneissic complex. They are brought together to the south-west by a thrust-fault, and beyond their point of meeting the north-western of the two synclines is so much intruded by epidiorite and Erinpura granite that it is ultimately obliterated at about where the other, south-eastern, syncline becomes the sole component fold of the synclinorium and so persists, as I have said, for a distance of about forty miles along its length, with a breadth of some six miles. This decrease in width is in part due to the smoothing out of minor folds and in part to the Alwar series at the base of the Delhis having almost died out for a space, to reappear again to the south.

South of the constriction the synclinorium widens again owing to additional folds appearing, to the coming in again of the Alwar series in force and also to deeper plunging synclines bringing in the highest beds of the central core. Here also igneous intrusion, principally the Erinpura granite, increases towards the south-west, obliterating the component formations *en echelon* from west to east until in Idar State only the Alwar quartzites are left where the synclinorium disappears below the alluvium of Gujarat.

In the northern part of the synclinorium both the strong quartzites and the basement grits of the Alwar series are in force, the latter becoming coarse conglomerates with strangely flattened and elongated cobbles at Barr and Srinagar. As a rule the basement beds here are arkose, the felspar being derived from the abundant granitic material in the pre-Aravalli gneisses upon which they rest unconformably.

South of the constriction the basement beds of the main synclinorium are fine-grained quartzites with intercalations of biotite-schist, as they are derived from the underlying Aravalli phyllites, which yield on disintegration no coarse felspar and no pebbles. Out to the east, however, is a line of faulted outliers of the Alwar series, in which arkose conglomeratic grits are strongly developed, as they rest upon the granite-intruded pre-Aravalli gneisses.

The Kushalgarh limestone[4] and the closely associated Hornstone Breccia, which in Alwar State separate the Alwar series from the Ajabgarh series, are not found outside Alwar.

In the country now described, *i.e.*, from the Sambhar Lake southwards, the lowest division of the Ajabgarhs is typically a great thickness of biotite-schists intruded with pegmatite in massive dykes and sills, and with aplite in veins and *lit-par-lit* injection; as a rule there is as much igneous material present as sedimentary, and excellent examples are seen of the transition from phyllite through biotite-schist to composite gneiss formed by the interfoliar permeation of biotite-schist with aplite.

The middle division, the "calc-schists," in their least metamorphosed phase are calcareous shales and impure limestones, seen only in two narrow synclines folded into the Alwar quartzites in the extreme south. These form the Mundeti series[5] of Middlemiss. Except in these two narrow

[4] *Mem. Geol. Surv. India*, **1917**, **45**, pt. 1, 56-72.

[5] *Mem. Geol. Surv. India*, **1921**, **44**, pt. 1, 53-61.

synclines and the isolated exposures of the "Mundeti series" in Idar, the "calc-schists" attain a higher degree of metamorphism, and have a surprisingly uniform character throughout their great length of outcrop. They are straightly banded, flaggy rocks, the banding being certainly the result of the original stratification and is now due to the alternation of dark layers rich in biotite and actinolite with pale layers of felspars, tremolite and diopside. The amount of igneous intrusion is generally less than in the case of the biotite-schists, and it occurs more as large sills and dykes of pegmatite, *lit-par-lit* injection being scarce.

The upper division of the Ajabgarhs, the "calc-gneisses," in its less altered phase in the north-east is a series of dark, banded biotitic and siliceous limestones, passing gradually along the strike to the south-west into "calc-gneisses". In these the banding, which is essentially the same as the banding in the original limestones, is broader and more variable in composition and in width than in the "calc-schists" and is more irregular, often being characterised by extraordinary contortion. In the "calc-gneisses" bands composed largely of carbonates (calcite and dolomite) alternate with bands rich in silicates (felspars, diopsides and amphiboles), the former being more soluble than the latter, which stand out in relief on weathering. In both "calc-schists" and "calc-gneisses" the present banding is essentially the same as the original stratification but metamorphosed; this consisted of alternating layers of calcareous sediment with argillaceous and ferruginous sediment.

The earliest intrusives in the Delhi system are epidiorites and hornblende-schists, originally basalts and monzonites, which are in particular abundance along the north-western flank of the synclinorium. Ultra-basic rocks are represented by talc- and chlorite-schists and by a group of small plugs of unfoliated talc-limonite-serpentine-magnesite rock, probably much younger than the former schists.

The principal post-Delhi intrusive is the Erinpura granite, in bodies of all sizes, and with wide variations of texture and degree of foliation. Its earliest forms were probably aplite veins and foliated granite sheets, followed by stocks and batholiths of larger sizes, composed of granite coarser in grain, more biotitic and often unfoliated; the last manifestation was the widespread pegmatite swarms.

Later than the Erinpura granite and earlier than the Malani volcanic series is a suite of basic and ultra-basic rocks found by Coulson[6] in Sirohi State, comprising picrite, pyroxenite, gabbro, dolerite and basalt. It also includes a sodalite-syenite; this is quite distinct from the soda-syenites[7] of Kishengarh State at the other end of the Aravalli range, which are probably pre-Delhi in age.

The Jalor and Siwana granites with their granophyres, porphyries and rhyolites, form the Malani series,[8,9] which has a wide development on the plains to the west of the synclinorium. The Idar granite of Middlemiss,[10] which was formerly supposed to be the same as the Jalor and Siwana (Malani) granites, has at the end of this field-season been traced into continuity with the main Abu-Erinpura batholith of the Erinpura granite, and the outcrops of the Malani series are thus confined to the west of the synclinorium and the Aravalli range.

Youngest of all is the dolerite which cuts the Delhis and the Malanis in a few plugs and dykes and may perhaps be related to a dolerite which intrudes even the Semri series or Lower Vindhyans far to the east in Mirzapur district.[11]

The Delhi system is characterised by a greater variety and abundance of igneous intrusives than either the Aravalli system or the Raialo series and by the fact that its sedimentary rocks usually attain a higher grade of metamorphism, particularly in the south-western part of the synclinorium, than the much older Aravallis outside it. It is believed that the plethora of intrusions was not to any important degree the *cause* of metamorphism but that the rocks of the synclinorium had reached their present metamorphic stage before the almost universal pegmatite, at any rate, had pervaded them. The Erinpura granite has, it is true, in some places produced local extra metamorphic effects on the calc-gneisses, but both calc-gneisses and calc-schists are uniformly in their usual highly metamorphosed

state over great areas and at great distances from any body of Erinpura granite.

Pegmatite veins were never seen to produce any marginal effects on the calc-gneisses and calc-schists, and in considerable areas free from pegmatite they do not differ from those in tracts riddled with pegmatite. Though not cause and effect, igneous intrusion and metamorphism are doubtless related in both being effects of the same cause,—deep folding by which the rocks were brought within the range of high temperatures and pressures and into contact with rising granite magma.

The Delhis appear to have been deposited in a geosyncline which was subsequently laterally compressed and elevated into a mountain range, the deeply folded roots of which are now laid bare. The two major unconformities, at the base of the Aravallis and at the bases of the Delhis and Raialos respectively, were of sufficient magnitude for the underlying formations to be highly folded and for deep-seated plutonic masses to be laid open by denudation. In the Raialo-Delhi interval similar folding took place but no post-Raialo and pre-Delhi igneous rocks have been detected.

Additions to the London Zoo.

We learn that the Prince of Wales presented to the mammalian section of the London zoo a giraffe-like specimen commonly known as the Okapi. This animal is known to the zoologists from a long time and we read that Sir, H. Johnston made a present of the skin, two skulls and the bones of the feet of a new genus of Giraffidæ secured from the Belgian Congo to the Nat. Hist. Society, London, as early as 1900. On examination this turned out to be the new genus *Ocapia johnstoni.* The genus *Ocapia* contains a single species *O. johnstoni.* Peculiarly, however, the animal which is about the size of a Sable antelope, incorporates in itself the striped side skin of the Zebra on its hind and forelimbs and the head of the giraffe *minus* the horns. The body and tail are coloured uniformly reddish brown. Naturalists tell us that he is a very shy creature and exhibits a predilection for choosing the thick recessus of the forests, but always lives in pairs. As regards the position of the animal in the scale of evolution, we know from the study of the skull that it is intermediate between that of the giraffe and that of the extinct Samotherium of the lower Pliocene of Europe.

The rare and proverbial blood-sucking bat—the Vampire—is a native of tropical America. Though small in size, it possesses a sharp set of teeth by means of which it is capable of inflicting painless wounds and then "licks" the oozing blood by means of the tongue with such rapidity that a regular sanguinous stream is seen to enter the mouth. For a long time the use of the long thumb was not known and now after a careful study Ditmar tells that it is used as feet for progression on the ground.

Wood Preservation in India.

By S. Kamesam, M.I.E. (Ind.),
Forest Research Institute, Dehra Dun.

In spite of all the efficient salesmanship and propaganda of cement and steel interests in India, wood is still very widely used for construction purposes. At the same time, for some years, wood has been gradually losing ground as a structural material. When timber was more plentiful, and steel and cement were less easily available and were more expensive, the urge for its proper use was not so apparent. In these days of competition, wood is used only in places and for purposes where it is not only initially less expensive than steel and cement, but where it is also cheaper in the long run. If a much longer life than what can be obtained with most raw untreated timbers of India cannot be secured, wood will be rapidly ousted out of the structural field. It is this aspect that brings us face to face with wood preservation by the application of physical and chemical principles. Naturally non-durable wood has to hold its own not only against non-cellulosic structural materials that are available in the market, but against the more naturally durable timbers.

A tree saved is a tree grown. It is wood preservation that makes one tree serve the purpose of even four or five trees, as with most Indian timbers, wood preservation augments the life by 400 to 500 per cent. Hence the wood preserver is not only aiding forestry, but is making forestry pay by the conservation of forest resources, and by the elimination of waste to a minimum.

What is a handicap with raw untreated timber becomes an asset when once wood preservation is employed. The so-called "katcha" timber for which people hardly pay anything in the timber-yard at present becomes very much more valuable than the expensive heartwood when once it is chemically preserved, as being almost invariably much more porous, it absorbs more preservative and to a greater depth. The aristocratic position held by the naturally durable timbers like teak and deodar in India is due to a poison with which they are endowed by Nature. In a scientific age like the present, tables have been turned by creative chemistry against a number of natural materials by superior and artificial materials that are more suitable and efficient for coping with certain specific conditions encountered in practice. When once timber is submitted to modern wood preservation processing, most of the porous timber that is despised and rejected at present will be more valuable than the so-called hard and durable timbers which cannot be filled up by impregnation with fire-proofing chemicals, dyes, etc. While the ordinarily despised pine can be fire-proofed, teak cannot be.

There are in the Indian forests several woods that are mechanically strong for almost any structural purpose, and stronger than pine and fir which have been widely employed for even railway bridge construction in the United States of America and Canada, but owing to their want of resistance to white ant and fungus attack, they are not used for construction work. In some cases, wood has got a bad name by its having been used unwisely. It can give only a short life if not chemically preserved. The same is the case with leather. Raw hides perish very much more rapidly than tanned skins. Unpainted or ungalvanised steel or iron perishes rapidly in a moist climate. Even cement concrete, unless special chemicals are included and unless properly made and cured, cracks under frost, and the cement is dissolved out if it is in contact with water for several years. Even the best of structural materials requires some kind of protective chemical treatment for resisting the disintegrating forces of Nature.

Besides fire, the two most important agents that tend to destroy wood, especially structural timber during service, are wood-boring insects and fungi. As iron and stone disintegrate through inorganic processes, unprotected wood is destroyed through decay. It is only Nature's cycle of creation and destruction that is incessantly going on. Decay is caused by low forms of plant life which, being incapable of photo-synthesis, feed on carbohydrates that have already been formed and are available. They produce an acid that dissolves organic substances, facilitating assimilation. The four requirements for the growth of fungi are oxygen, moisture, a favourable temperature and food. When submerged in water, or in the earth below the " level of water of saturation", wood has been known to last hundreds of years. In perfectly dry

situations, it is not affected by fungus for an almost indefinite period. A damp condition, accompanied by poor ventilation, offers very favourable conditions for fungus attack. It is for this reason that timber fence posts and joints, where water tends to stagnate, etc., decay rapidly. Wood destroying fungi cannot grow at very high or very low temperatures. There is hardly any wood destroying fungus that can live above 40° C. while very few can live below 15° C. Most fungi—especially the so-called "wet" fungi like *Coniophora cerebella*—grow vigorously between 20°C. and 25° C. A few of the so-called dry fungi like *Lenzites thermophila*, which attack the tops of poles and posts, thrive vigorously between 30° C. and 35° C.

The wood itself supplies the fourth requirement—namely food. It is interesting to note that some fungi attack only the cellulose component of wood while others the lignin component.

To prevent fungus attack, it is obviously necessary to deprive it of one or more of the four above mentioned requirements. In all outside locations and in most indoor locations, it is impossible to deprive them of air, or to keep them at a very high or very low temperature. The best and most practicable way is, therefore, to poison the food supply. This is the principle on which successful wood preservatives are based.

Wood-boring insects, including white ants, attack timber almost irrespective of its moisture condition, although a certain minimum moisture content in wood appears to induce insect attack more readily. The action of wood preservatives on wood-boring insects is similar to that on fungi which cannot feed on poisoned wood without being killed.

Modern wood preservative treatment performs three kinds of service. Firstly, it increases the durability life of wood by over two or three decades even on exposure to very severe conditions saving several times the cost of replacing the structure, and the inconvenience involved in such frequent renewals. Secondly, it makes the present worthless sapwood even more durable than the heartwood of even the most naturally durable species. This removes the necessity for imposing restrictions on sapwood content and distribution in structural timbers. It, therefore, permits closer utilisation. Thirdly and lastly, it enables our so-called junglewoods and poles in the round, which are invariably of low natural durability,
used widely for construction purpose

A successful wood preservative sho
toxic enough to kill wood-boring inse
well as fungi. It must be available in
quantities and be of uniform compo
It should be also not high-priced. Als
preservative should neither volatilis
get washed out from wood when ex
either to running water or to moist soi

There are several wood preservatives
market to-day. The Forest Research
tute, Dehra Dun, has tested several
wood preservatives against fungus and
ants during the last about 25 years.
of the preservatives that were tested
good results for the first year or so
owing to either volatilisation or lea
the treated specimens of wood comm
to fail rapidly after that period.

Generally speaking, there are two kin
wood preservatives. One kind is repres
by oils like coal tar creosote. Such pres
tives are almost insoluble in water, but te
volatilise. Coal tar creosote has given
lent results as a wood preservative, b
very expensive in India besides giving
a pungent odour. The other class consis
water-soluble salts. These are very u
for outside moist locations only if they
be "fixed" to wood. Five of the
important inorganic elements that
been employed with success in the past
zinc, fluorine, mercury, copper and ars
The first two elements have not been f
to be very effective against white ants, v
proving efficient against fungi. They
therefore, almost useless for Indian co
tions. The mercury wood preservativ
too expensive compared to the remai
four, and also cannot be employed
pressure impregnation in steel cylin
Therefore, our choice falls on copper or
arsenic.

On account of wide variations in temp
ture and humidity in India, wood, alm
invariably, splits under service condit
so that as deep a penetration of the prese
tive as possible should be secured if trea
wood is to give efficient service in out
locations. This necessitates a pressure
pregnation. The most recent experie
in India and abroad has demonstrated
for a unit of money, an optimum comb
tion of copper and arsenic affords the m
efficient protection to wood against w
ants and fungi. Such a preservative, to
successful, should not only be easily sol

in water, but while forming a compound in wood that is almost insoluble in water, like limestone, the compound should be soluble to form a lethal dose, in a very dilute acid of a pH-ion concentration of between 4 and 5, an acidity corresponding to that produced by wood destroying fungi when they attack and assimilate wood substances in Nature. It may be stated that the acidity corresponds to about $\frac{1}{3}$ per cent. concentration of concentrated acetic acid in water. The preservative should not only be stable in contact with steel and cement, but should not corrode steel. A successful wood preservative satisfying all the above conditions was recently developed by the writer at the Forest Research Institute, Dehra Dun. It is called *Ascu*.

The next aspect that merits consideration is the method of applying wood preservatives. Generally speaking, there are three methods. The preservative may be either impregnated under mechanical pressure, or be introduced into wood by allowing it to soak for several hours in the preservative fluid. A third method of application is either with a brush, or a spray pump. Where timber is employed in sheltered locations, if it has been well air-seasoned to start with, it can be treated with success either by soaking or brush-painting. For use in outside locations as with railway sleepers, especially when timber is partially buried in the earth, as in the case of a pole or post, it should be pressure-treated for obtaining the best results. Otherwise, timber splits and cracks. The planes of cleavage thus formed will serve as channels for the ingress of white ants and wood destroying fungi spores.

From the point of view of distribution and content of preservative fluid in wood cells, there are two general methods of wood preservative impregnation, one is the "full-cell" impregnation in which the cells, after displacing the air in them, are filled by the preservative fluid. In the "empty cell" processes—the second general method—wood cells are only lined with a coating of the preservative so that by employing them, a considerable saving in the cost of preservation results. Up to about 80 to 90 per cent. of the preservative originally introduced under pressure can be recovered. Each method has got its own field of application. While in the "full-cell" processes, exposing the timber to a vacuum, or boiling it in a vacuum are the common lines of procedure; in the "empty-cell" processes, either the air that is contained in wood is compressed by superimposed hydraulic pressure, or air from outside is injected under pressure into wood before the antiseptic fluid is forced so that a high pneumatic pressure is, initially, created in the wood. When the superimposed hydraulic pressure is broken, compressed air inside the wood comes out rapidly bringing with it a large quantity of the antiseptic fluid that has gone in due to the hydraulic pressure. The two most popular "empty-cell" processes are called after Lowry and Rueping, the latter having the distinction of being the inventor of the most effective "empty cell" process—which involves the initial injection of air into wood—known to-day.

If the best service is to be obtained from treated timber, not only expert technical advice is necessary as regards the selection of the most suitable wood preservative, but also regarding the most efficient and economical method of treatment. Several specifications for treatment as well as preservatives are known. A selection is imperative. A thorough knowledge of the structure of the timber to be treated is essential. Also, considerable experimentation regarding the treatment characteristics of the timber in question is a necessary prelude for obtaining the best results.

As far as India is concerned, about a hundred of the more important commercial timbers and bamboos have been subjected to investigation during the last twelve years by the Wood Preservation Section of the Forest Research Institute so that the public may write for advice regarding any problem connected with the preservative treatment of Indian timbers and bamboos.

The next factor that requires consideration is the cost of antiseptic treatment. Usually actual cost of pressure treatment which includes interest and depreciation on the investment on the erection of a suitable plant, the cost of handling timber in the yard, etc., works out at about 2 annas to 4 annas per cub. ft. whereas the actual cost of the preservative is very variable. In the case of most preservatives, it varies between 2 annas and 8 annas per cub. ft. With the soaking and brush treatments which are not very effective for outside locations the cost of treatment is naturally very much less.

Timber or bamboos can also be "fire-proofed" which enables the cellulosic material to resist the tendency to burn. The material merely chars so that the charred portion

protects the interior strata from combustion. The three main principles underlying an effective fire-proofing treatment are the impregnation into, or application to, wood of a chemical that would either form a kind of glassy material by fusing on exposure to heat, and thus prevent the access of oxygen to the wood, or will liberate either water vapour or inert gases when the temperature of the wood rises above 150°C. or 200° C. As the water vapour or inert gases dilute the oxygen around the timber, combustion is retarded. The most popular and representative fire-proofing chemicals are sodium silicate, borax and ammonium salts. The practical method of fire-proofing timber is similar to preservative treatment. The cost is also about the same per cub. ft. Some of the more important uses to which chemically preserved timber can be put to with economy not only initially, but in the long run in India are noted below :—

1. *In the railways.*—Sleepers, crossing-planks, roof-trusses, posts, joists, ceiling, planking, doors, windows, partitions, fences, trestle bridges, overhead and foot bridges, culverts, telephone and signal poles, sign-posts, carriage and wagon superstructures, conduit planks, cooling structures, platforms, bulk-heads, water tanks, pile foundations, flooring planks, paving blocks, etc.

2. *In the highways.*—Truss bridges, trestle bridges and bridge approaches, culverts, sign-posts, bulk-heads, retaining walls, guard rails, fence posts, bridge floors (especially of pontoon bridges), etc.

3. *Overhead electrical construction.*—Transmission, distribution, lighting, telegraph and telephone poles, cross-arms, insulator pins, pole struts, guy-blocks.

4. *Building construction.*—Pile foundations, doors and windows, joists, rafters, wall-plates, sub-floors and floors, shingles, roof-trusses, garden structures, summer houses, garages.

5. *Rural construction.*—Posts, poles, bamboos, rafters, joists, flooring, cart-wheels, doors and windows, cattle shed roofs, poultry houses, aqueducts, irrigation channels, garden creeper and vineyard stakes, bamboo supports to sugarcane and other crops.

6. *Factory and mill construction.*—Roof-trusses, building timber of various kinds, wood tanks and chutes, etc.

7. *Marine construction.*—Wharf and pier timbers, fenders, sleepers, roof-trusses, ship and boat building, breakwaters, causeways, overhead bridges, loading docks, etc.

8. *Mine construction.*—Head-frames, shaft houses, gallery lining, tipples, sleepers, coal bunkers, flumes, trestles, tanks, conduits, electrical supports, permanent haulage ways, etc.

The relative economy of treated timber in India may be gauged from the fact that while any species of timber has, weight for weight, about the same strength as iron and steel, it costs, especially in the round, only a fraction as much as metals. Also the cost of working timber is considerably less than that with metals. Since in most cases, even in outside locations, as properly treated timber can be confidently expected to give a life of about 25 to 30 years (a period which synchronises with the "obsolescence" period of most structures), treated timber appears to be not only the most up-to-date structural material but the most efficient and economical building material in India. In these days of engineering and scientific progress, accompanied by a corresponding rapid change of æsthetic ideas and fashions, there is a very strong case for the use of chemically preserved wood in India for structural purposes. Commercial wood preservation has just been born. The Indian Railways and the Mysore Government have treated in their pressure plants several lakhs of railway sleepers and electrical poles. The Government of Madras have been operating, for some time, two small *Ascu* wood preservation plants. The Government of Travancore are putting up shortly a large wood preservation plant. The Government of Bhopal will be shortly using several thousand cub. ft. of *Ascu*-treated timber. The Government of the United Provinces are installing a few thousand electrical distribution *Ascu*-treated poles. The *Ascu* Wood Preserving Agency, the only private wood preservation company, has been operating two large wood preservation plants in Northern India.

With efficient and extensive organisation, wood preservation will prove to be a great blessing to this tropical country, where fine timber is not only a rapidly growing crop, but cheap and efficient wood-working labour is available throughout the country.

Letters to the Editor.

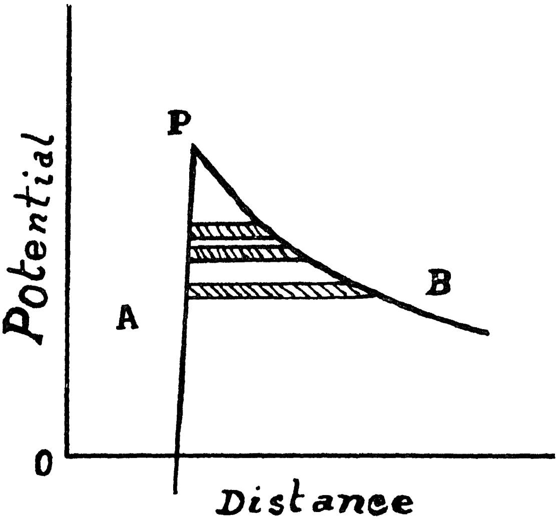
A Note on the Potential Barrier.

IN developing the theory of spontaneous disintegration of α-particles from radioactive substances, Gamow has introduced the idea of a potential barrier in the nucleus. It is assumed that within the nucleus the potential varies as shown by the curve.



Thus at a nuclear distance greater than OP the potential is Coulombian varying inversely as the distance. On the other hand for distances less than OP the potential decreases with the distance.

The α-particles are packed within the region OP. If by some means an α-wave crosses the peak P of the potential wall, it will be set free by the Coulombian repulsive force. To explain this crossing, Gamow has to fall back on Heisenberg's *Principle of Uncertainty*. But it appears to me to be fallacious to apply Heisenberg's principle to this case. The rate of disintegration, however small, has a definite value. It is a phenomenon known with a certainty. It is not, therefore, proper to take help of the uncertainty principle which gives a measure of the "unknowable" to explain what is known definitely with definite experimental values. Moreover, if a theory based on the "certainty principle" is available it would be scientific to give it preference to the one developed on the basis of the "uncertainty principle".

After Gamow's theory Born, Sexl and others deduced a similar formula on assuming the reflectivity and the transmissibility of the barrier. Obviously there can be no objection, as in Gamow's theory, to such an assumption. However, in all these wave-mechanical theories it is assumed that

the energy of the disintegrating α-particles is partly real and partly imaginary. The assumption of particles having imaginary energy is certainly open to criticism. In a recent paper on the subject Sexl[1] has suggested that one has to make the above assumption because the waves within the nucleus are damped.

Before Sexl's paper, just mentioned, was published the writer[2] had developed the wavestatistical theory of disintegration. It was assumed that, on account of a very high value of density, the phase space corresponding to the hard core of the nucleus is viscous. Due to the viscosity, the hydrodynamical waves in the phase space are naturally damped. The theory, it may be noted, has been developed only on the above assumption which is perfectly justified. No assumption regarding imaginary energy is necessary. Further, in so far as a definite nuclear property causing disintegration is assumed, the theory is free from any "uncertainty objection".

In developing the wavestatistical theory the writer has followed Rutherford's model of nucleus. However, it may be mentioned that now-a-days the picture of potential barrier seems to be replaced by Rutherford's model. But it can be easily seen that there is close agreement between the two. It is evident that the sphere of radius OP is Rutherford's hard core, where the whole of the nuclear charge is collected. Beyond OP there is the neutral shell of Rutherford. There are stationary orbits in the neutral shell. And any particle going out of the hard core is caught for a while in one of these resonance levels and *vice versa*. This explains the existence of holes in the barrier as indicated by shades in the figure.

Depolarisation of the Light Scattered by Heavy Water.

10 grs. of heavy water supplied as 99·5 per cent pure by the Ohio Chemical Manufacturing Co., is contained in a pyrex glass double bulb which is sealed off after evacuation. The liquid is collected into one of the bulbs from the other by slow distillation. When thus purified, it is found to be quite free from dust. The bulb is painted black all over leaving two small windows for illumination and observation respectively and the depolarisation of the transversely scattered light is measured using sunlight focussed by means of a long focal length lens as incident radiation. The track representing the horizontal component is seen to exhibit a distinct reddish tinge and the depolarisation is obtained as 0·04 after applying a correction for the convergence of rays in the incident beam. This result may be compared with the depolarisation of about 0·06 observed for ordinary water and shows that the heavy water molecule is similar to that of the ordinary water molecule in respect of possessing only a feeble optical anisotropy.

Inhibition in the Benzoin Reaction.

FOR some time this laboratory has been engaged in a study of the kinetics of the benzoin reaction between solid potassium cyanide and benzaldehyde, in the absence of solvents or diluents. It has been shown[1] that two reactions occur, a heterogeneous reaction between solid potassium cyanide and benzaldehyde, and a homogeneous reaction between benzaldehyde and the trace of potassium cyanide which is dissolved by benzaldehyde. This latter reaction is autocatalysed by benzoin and can occur only if benzoin is present.

It has also been shown that the heterogeneous reaction is subject to inhibition in the presence of, for example, potassium iodide or quinol. The inhibition appears to be due to the adsorption of the inhibitor on the surface of the solid potassium cyanide.

This is confirmed by the fact that benzaldehyde contaminated with a trace of an inhibitor can be made to give the normal rate of reaction by allowing it to stand at room temperature in contact with a quantity of solid potassium cyanide too small to produce a measurable amount of benzoin during the time of the purification.

We have now succeeded in showing that with certain substances, inhibition occurs in the presence of small proportions, for example, a fall in the rate of reaction can be detected with benzaldehyde containing one

part in 10^7 of quinone, or one part in 5×10^5 of iodine, or one part in 2×10^4 of sulphur.

Small quantities of water and of certain alcohols accelerate the reaction, but the effect is not so marked as with inhibitors. Acceleration has been detected with, for example, with 1 part of water in 100 of benzaldehyde.

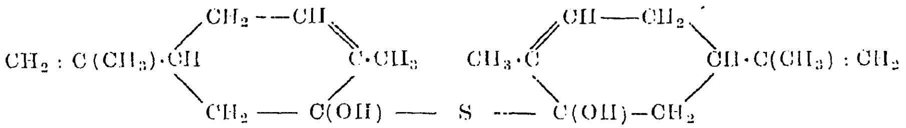
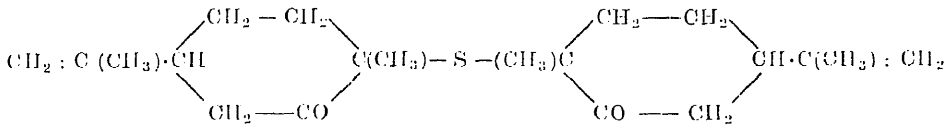
A Note on the Absorption Spectrum of Carvone 'Hydrosulphide' and Its Constitution.

ALTHOUGH the formation of crystalline additive compounds between α-β unsaturated ketones and hydrogen sulphide has been known long since,[1] the constitution of these 'hydrosulphides' is still a matter of some controversy. In the case of carvone 'hydrosulphide' for example, which consists of 1 molecule of hydrogen sulphide and 2 molecules of the ketone, the following structures have been proposed from time to time (I, II, and III).

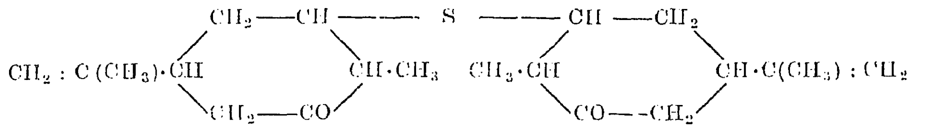
Of these, Formula I due to Harries and Stirm[2] is based on the non-formation of any oxime, semicarbazone or phenylhydrazone by the compound, while Formula II



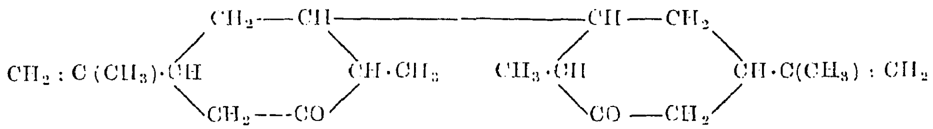
I



II

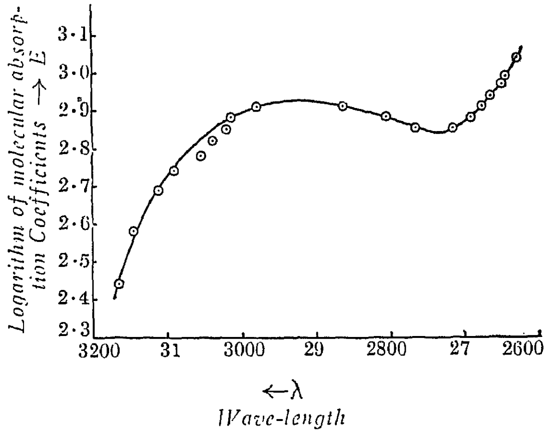


III



IV

put forward by Wallach[3] derives its support from the formation of a dimolecular compound (IV) on addition of hydrogen. The preparation of a dicyanohydrin which readily decomposed to the corresponding dinitrile led Steele[4] to propose (III) for the compound. In order to decide between these alternatives, a quantitative measurement of the ultraviolet absorption of the compound was made with the help of the 'Spekker' spectrophotometer of Hilger. The curve of molecular extinction coefficients given below was obtained with a 1 cm. length of a solution in chloroform of 0·61% concentration. The band at $\lambda = 2900$ Å furnishes direct evidence for the existence of free CO groups in the molecule. The formula of Harries and Stirm is therefore excluded.



Absorption Spectrum of Carvone 'Hydrosulphide'.

The formation of a tetrabromoderivative[5] and the recent work of Hooper, Macbeth and Price[6] on the bis-dinitrophenyl hydrazone of the substance is also in favour of this view. The influence of negative groups like the CO group in making the neighbouring ethenoid carbon atoms more negative is well known[7] and hence the structure proposed by Steele (*loc. cit.*) is put forward as the most probable constitution for carvone 'hydrosulphide'.

Is there a Racial Factor in Metabolism ?

RECENT investigations have shown that the basal metabolism of Indians is considerably lower than that of Europeans or Americans and the question has been raised whether a definite racial factor is involved. (*Cf.* Mason[1] who investigated the basal metabolism of South Indian women.) It is interesting to examine, from this point of view, the results of a study made in this Laboratory on the Nitrogen distribution in the urine of South Indians and to see if the metabolic products in the urine show any indication of racial peculiarities. The results quoted in Table I are based on the analysis of the urine of thirty-two normal individuals, including fourteen vegetarians and eighteen non-vegetarians.

The significance of these results from the present point of view is that while the value for Total N. and for Urea-N. (which latter represents the main product of exogenous metabolism) are very low compared to Western standards and indicate a low level

TABLE I.

	Total N.			Urea-N.			Creatinine Coefficient = m.g. Creatinine-N. / Body weight in Kilos		
	Average	Max.	Min.	Average	Max.	Min.	Average	Max.	Min.
South Indian General ..	7·10	11·11	4·11	4·92	9·06	3·02	9·27	12·8	5·56
South Indian Vegetarian ..	6·20	8·26	4·11	4·30	5·18	3·08	8·48	12·8	5·56
South Indian Non-Vegetarian ..	8·01	11·11	4·17	5·54	9·06	3·02	9·95	12·7	7·30
Europeans	18·0	..	..	16·33	..	..	9·0	..	..

of protein ingestion, the endogenous metabolism which is little affected by the nutritional state of the individual and which might be expected to show a racial peculiarity, is, as measured by the creatinine coefficient, not lower than that of Europeans and Americans. Attention may be drawn in passing to the difference in the averages for the creatinine coefficients of vegetarians and non-vegetarians. So far as this small difference is of any significance, it seems to be in keeping with the work of Abderhalden and Buadze[2] and others who have demonstrated a slightly increased creatinine excretion in dogs after feeding certain amino-acids in massive doses and over a sufficiently long period.

As the creatinine coefficient is generally taken as an index of muscular efficiency, it is satisfactory to find that this factor cannot be correlated with the observed low basal metabolism of South India. The views of the earlier investigators on basal metabolism may be summarised in the words of Lusk[3]: "On the basis of the whole of the evidence it does not appear wise to state that the influence of race or a tropical climate may greatly reduce the basal metabolism." Whether this is not, after all, the correct view and whether under-nutrition, such as is shown to exist in regard to proteins by the present study, is not a sufficient explanation for the low values for Indians obtained by Mason

and others can only be settled by carrying out basal metabolism and dietary studies simultaneously on groups of individuals at different levels of nutrition.

On the Absorption Spectra of the Halides of Some Elements of the Second Group: $CdCl_2$; $CdBr_2$; CdI_2; $ZnCl_2$; $ZnBr_2$ and $SrCl_2$.

THE absorption spectra of the above halides of the elements of the second group were studied by the same method of experimental procedure as that adopted by R. Samuel[1] and the regions of the maxima of absorption obtained by plotting the values of log K against wave-length. The salts are very hygroscopic and the preparation of solution offered some difficulty as much heat was developed. In the case of $ZnCl_2$ and $ZnBr_2$ a lower concentration could not be prepared as the addition of water precipitated the salt in a form of colloidal solution which dissolved on the addition of a little HCl and HBr respectively showing hydrolysis. The curve for $ZnCl_2$ indicates that it does not obey Beer's law.

Salts	Maxima of Absorption Wave-length in μ	Log K values
$CdCl_2$	260	−0·76
$CdBr_2$	273	−0·06
CdI_2	No maxima of absorption	
$ZnCl_2$	338—300 (5M) .. 255 (5M strength) 255—227 (M/2 ,,)	−1·48 −0·28 −0·48
$ZnBr_2$	308.. 276	−0·28 −0·08
$SrCl_2$	420 .. 346..312	−1·26 −0·96 −0·69

The above table shows the wave-length of the maxima of absorption of different salts with their log K values.

Details will be published elsewhere.

A New Device for the Insect Transmission of Spike Disease of Sandal.

IN the course of experiments on the insect transmission of the spike disease of sandal, we experienced a serious shortage of spiked plants having plenty of diseased foliage to serve as the source of infection for the vectors. This difficulty was overcome by conducting the experiments with spiked plants growing under natural conditions in an artificially raised plantation. The plants selected for the purpose offered a branch in a suitably low and oriented position so that the diseased branch could be inserted into the experimental cage, thus providing the source

of infective material. The cage receives also the healthy sandal plant growing in a pot

(Fig.). This method has several advantages over the usual method of providing spiked plants in pots which do not survive the feeding by insects. The diseased branch, on the other hand, being a part of the big plant, is capable of withstanding the attack of the vectors more successfully than the small independent plant with an equivalent amount of branch and foliage. Often, it is advantageous to decapitate the other branches and divert the entire nutriment available, for the vigorous growth of the diseased branch utilised for the experiment. This device has successfully solved the problem of the supply of spiked plants for our transmission experiments and it is hoped that this method may find useful application in the investigation of the other allied diseases.

Oxidative Digestion of Organic Nitrogen.

IT was shown in a previous communication[1] that nitrogen in soils and biological materials can be estimated by a process of oxidative digestion. The present note relates to (*a*) the nature of the products formed under such conditions and (*b*) an improved procedure for their inclusion in the estimate of total nitrogen.

The observations may be summarised as follows :—(1) When an aqueous suspension (or solution) of soil or other biological material is heated slowly with dichromate (or chromic anhydride) and sulphuric acid as in the usual procedure for the wet combustion of carbon, there is invariably some loss of nitrogen, the extent of such loss being inversely related to the rate of heating. The mechanism of this loss is still not clear though there is some evidence to show that ammonium dichromate, which is formed as an intermediate product, may undergo slight decomposition, yielding elemental nitrogen. The loss can be avoided, however, by first heating the material to be digested with water and sulphuric acid and then adding the oxidising agent to the boiling (or nearly boiling) mixture. (2) Small quantities of nitric acid are formed during the digestion. This is supported by the independent observations of Narasimhacharya.[2] The quantities are ordinarily too small to appreciably affect the estimate of total nitrogen even if the digest is boiled without condensing the ensuing vapours. On the other hand, the original material itself may contain useful amounts of nitrate which may be lost if proper precautions are not taken. The use of water or air-cooled condenser, as suggested by Narayanayya and Subrahmanyan (*loc. cit.*) helps to retain all the nitrogen in this form. Subsequent reduction of the digest with zinc or reduced iron in acid medium or Devarda's alloy in alkaline medium helps to include all the nitrate in the estimate of total nitrogen. More recently evidence has been adduced to show that even added nitrates can be retained in the digest and accurately estimated by adopting the above procedure. (3) It has already been shown (Narayanayya and Subrahmanyan, *loc. cit.*) that a part of the nitrogen is always retained in the digest and is not released by mere distillation with alkali. Further evidence has been obtained to show that the major part of this nitrogen is present in combination with the chromium in solution and is released on treating the digest with such reagents as are usually employed for reducing dichromate. The nature of the related compound (or compounds) is still obscure. (4) No information is available regarding the mode of association between nitrogen and the insoluble precipitate formed—especially in the case of soil—during digestion. It may nevertheless be mentioned that any nitrogen which may be present in that form is also included in the estimate of total nitrogen by treatment with reducing agents followed by distillation with alkali.

It was suggested by Narayanayya and Subrahmanyan (*loc. cit.*) that the total nitrogen in the digest can be estimated by boiling with zinc followed by distillation with excess of alkali. Unfortunately, all preparations of zinc (including some of the purest specimens) contain nitrogen. In some cases, the nitrogen content may be as high as that of the material to be digested. Reduced iron also contains nitrogen, though the latter is partly removed by pre-treatment with alkali. Since the major part of the zinc or iron is required for the reduction of unused chromic acid, it was considered desirable to use other reducing agents for that purpose. Among the various re-agents

that were tried, alkali sulphites were found to be the most effective.

Based on the foregoing and other observations, an improved method of oxidative digestion has been developed and will be described elsewhere.

Injurious After-Effects of Sorghum Growing.

WHILE working at the problem of the injurious after-effects of Sorghum in the black soil tracts of the Tinnevelly District, it was observed that, after Sorghum, the soils became much more compact and much harder than after the Spiked Millet and that their permeability was considerably reduced.

When examined in the laboratory, certain striking differences were observed in the cationic composition of these soils the results of which are given below.

It will be seen that—

(i) the exchangeable soda of the soil is greater when cropped with Sorghum than when cropped with Spiked Millet and

Exchangeable Bases in Millicquivalents per 100 gm. of Air-Dry Soil.

Head of analysis	Soil depths	Cholam*	Cumbu*	Cholam†		
				Before Sowing	At shot blade	After harvest
Soda	6″—12″	4·03	2·26	1·23	2·98	4·28
Potash	6″—12″	1·11	0·91	0·82	0·86	1·11
Magnesia	6″—12″	11·55	13·96	12·55	13·85	13·53
Total bases	6″—12″	55·31	55·23	56·10	55·70	58·10
Soda	12″—1′ 6″	3·55	2·56	1·36	2·66	3·44
Potash	12″—1′ 6″	0·90	0·95	1·07	1·04	0·99
Magnesia	12″—1′ 6″	14·21	15·35	13·62	12·93	13·48
Total bases	12″—1′ 6″	50·92	50·84	48·00	50·30	50·80

* Average of six samples. † Average of three samples.

(ii) the increase is continuous with the growth of the Sorghum crop.

Sorghum or cholam....*Andropogen Sorghum.*
Spiked Millet....*Pennisetum typhoideum.*

It is not known how exactly this increase in Sodium ion is brought about, but it goes a great way to explain the greater deflocculation and the changes in the physical condition of the Sorghum soils, more particularly their reduced permeability.

In addition, a good deal of evidence has accumulated, in the course of our work, which shows that the explanations usually offered for this phenomenon, *viz.*, soil exhaustion, particularly in nitrogen, toxicity due to the decomposition of plant residues are not in themselves adequate. For example, the injury to the succeeding crop is not seen unless the Sorghum crop is allowed to set seed. Addition of nitrogenous manures like Ammonium Sulphate did not remedy the defect nor did the incorporation of Sorghum stubbles brought from outside, give rise to the adverse after-effects.

It looks as though other causes than those abovementioned are responsible for the injury; the increase in Na-ion is probably one such.

On a Method of Preparing Large Thin Sections of Plants by Grinding.

IT is a well-known fact that palm-stems show a peripheral crowding of fibro-vascular bundles in their anatomical structure. This

arrangement and the lignification of the sclerenchyma, with the deposition of minerals make the peripheral zone hard and brittle to such an extent in old stems that it is not possible to cut large thin sections by any known means for microscopic examination.

The author while working on the anatomy of palm-stems had to face this difficulty. Various methods for softening such as hydrofluoric acid were resorted to without any success. Ultimately it was thought advisable to harden the entire structure, thus making it possible to grind it to microscopic transparency.

Attempts were made to deposit calcium carbonate and silica inside the cells but it was soon realised that filling the cell cavities with some grindable substance was not enough, as it failed to make the cell walls sufficiently tough to stand the horizontal pull of the grinding. Some substance was required which could be introduced not only into the cell cavities but into the cell wall itself, and later on made to set there with uniform hardness so that it could be ground like a stone. These properties were found in canada balsam, as it is possible to impregnate it uniformly in the whole tissue quickly and without any difficulty with the help of xylol, in which it is miscible in all proportions, and then allow it to set there first by letting the xylol evaporate slowly and then raising the temperature gradually.

For this purpose a transverse slice about 2 mm. thick was cut from a stem with a fine fret-saw. The slice was first boiled in water to drive out all the air and then dehydrated with 50, 70 and 90 per cent. alcohols first quickly and then more slowly, towards 100 per cent. The time varies with the size of the vessels and that of the lacunæ in the ground tissue of the type selected. The whole process up to 90 per cent. takes about 30 minutes. There is practically no harm done by the sudden changes of the grades of alcohol, as the peripheral tissue in palms is always hard enough to sustain the shocks and even the ground-tissue in that zone gets thickened with age. After 90 per cent. alcohol the case is otherwise. The material should be kept in absolute alcohol as long as possible with frequent changes for the purer absolute alcohol. In practice 24 hours are enough. When the dehydration was complete the alcohol was gradually replaced by xylol, and the material was left for another 24 hours in pure xylol. To this, later on, canada balsam was grad added and the xylol allowed to evap slowly in a bath till a syrupy solution re ed. The material in the syrupy sol was kept in the drying bath at a temper of about 50°–60° C. to evaporate the for 24 hours or less (depending on the t ness of the slice and other factors). O next day the material was fixed on a slab with pure hot canada balsam just a fossil slide. The fixed material was ground with fine carborundum powde a plane surface, and then it was unfixe softening the balsam by heat and fixed with a ground surface towards glass. Then the other surface was gr down till the section became suffici transparent for microscopic examina When the required thickness was obt the carborundum powder was rem from the section by washing with xylo brushing with an ordinary painting b The section was then ready for mounti a permanent preparation.

Generally it is not necessary to stai sections as the tissue is found al differentiated in colour but if staini required then the balsam should be rem completely by constant washing with and then bringing the material into wat passing it gradually through the diff grades of alcohol in reverse order.

The author was able by this metho prepare sections for his investigatio comparatively short time and without culty. The time usually lost in sharpe razors was utilised in grinding the ma and even such hard and thoroughly lig and mineralised structures as the old s of *Bactris major*, *Areca catechu* and *Orec oleracea* gave excellent results. The sec obtained were thin enough to be pl graphed under a magnification of 50 meters. Sections prepared by this me are in fact indistinguishable from t prepared by cutting. It is also possibl this method to obtain sections of ti which are brittle or too fragile to be wo with a microtome. The author has succe in getting good sections from a well-d loped *Areca catechu* stem, in which case the central ground-tissue was found t mineralised. In the accompanying illu tion the ground-tissue is shown h magnified. The perfection of the me will be realised from the fact that the lac structure of the ground-tissue is seen i

"Dionyle P. W." for Rapid Penetration of Fixatives.

IT is well known that plant material containing air, for example, flower buds and leaves, etc., does not easily sink to the bottom of the tube containing liquid fixatives specially in those which do not contain alcohol and thus the process of fixation is not as rapid as it should be. When there is plenty of air within the tissues the material remains floating on the surface for a long time or it does not sink at all. Usually suction pumps or water aspirators are used to get rid of the air but in many cases even these are not of much help.

A French Engineer Chemist, Mr. Auguste Blondon of the firm S.A.P.I.C., 33, Quai de Seine, L' Ile-st-Denis, Paris, has recently manufactured a chemical product in the powder form known as Dionyle P. W. which, if added to any plant fixative, allows the material to settle to the bottom with great ease. I have seen Dr. A. Eichhorn using this chemical very successfully with roots, flower buds, etc. I myself have used it with success for fixing the ærial mycelium of Pythium. Dr. G. Archambault[1] has tried this chemical and is of opinion that it is very good for rapid penetration of fixatives. He compared the sections of plant material fixed with and without Dionyle in the fixatives and found that the addition of the chemical did not produce any undesirable effects. It has some physical action on account of which pieces of roots sink down rapidly in the fixatives, but in case of leaves and flower buds water aspirators may have to be used for about 2 to 5 minutes. Dionyle is an ether salt of β-naphthalene sulphonic acid with butylic alcohol and isopropylic alcohol. It is easily soluble in water and is neutral in reaction. During the process of its manufacture a little sulphuric acid appears which is neutralised by sodium sulphate, which is not bad for fixation.

In fact it is used in Zenker-formaol[2] fixative the composition of which is given below:

Bichloride of Mercury	.. 5·0 gm.
Bichromate of Potassium	.. 2·5 gm.
Sulphate of Sodium	.. 1 gm.
Distilled Water	.. 100 c.c.

To 9 c.c. of this add 1 c.c. of neutral formaline at the time of using the fixative.

Dr. Eichhorn adds Dionyle to any fixative whatever its composition may be.

In France this chemical is used as steeping agent in Dyeing Industry of wool and cotton in the proportion of 0·1 gm. per 100 c.c. of water. Dr. Eichhorn and Dr. Archambault use the same proportion for plant material. It is added to the fixative before the material is put for fixation or even afterwards. It is not necessary always to weigh it.

The Dionyle P. W. is very cheap and can be had from N. Boube 'e and Cie, 3 place St.-Andre-des-arts, Paris (VI). The price for 50 gms. is 4·50 francs and for 100 gms. is 8 francs, *i.e.*, Re. 0–14–0 and 1–10–0 respectively according to the present rate of exchange. It is better to keep it in glass-stoppered bottles.

A Rare Instance of Change of Tropism in *Arachis Hypogæa*, Willd.

THE ovary of the groundnut flower, after fertilisation, develops a stalk or gynophore at its base. It elongates rapidly carrying the ovary at the apex which piercing the soil buries the ovary, where it develops into a pod. The structure of the gynophore is almost the same as that of the stem. But, peculiarly enough, while the stem is negatively geotropic, the gynophore is always positively geotropic. This tendency is shown very early even when the gynophore is just a few millimetres long. In 1932, the authors came across a unique specimen of a groundnut plant of A.H. 32—a Spanish Bunch variety, grown under dry conditions (Fig. 1) in which the "pegs" or gynophores exhibited different degrees of geotropism :—14 pods

developed normally and produced seeds; 7 gynophores were quite erect showing

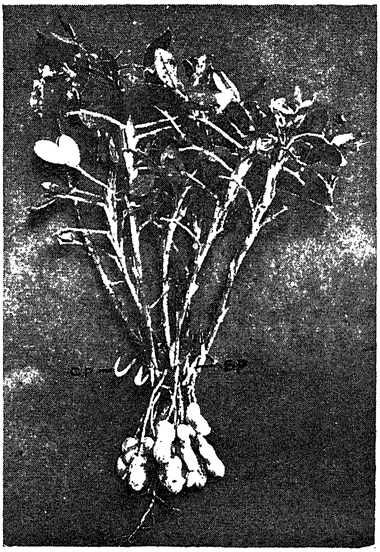

Fig. 1.

Groundnut plant with negatively geotropic gynophores. E.P.—Erect peg. C.P.—Curved peg. × 1/4 Nat.

complete, negative geotropism; 4 gynophores after a period of normal downward growth began curving upwards, exhibiting change of tropism.

There was development of chlorophyll at the dilated and pointed apices, *i.e.*, the ovule-bearing portion of some of the abnormal pegs. One of these was quite green like a stem. The abnormal pegs did not produce normal pods and seeds.

With regard to the other morphological characters there was nothing unusual. The few normal seeds obtained from the abnormal plant were sown; but the offspring was quite normal and no peg showed either partial or complete negative geotropism. The chances for the occurrence of the abnormality seem to be very rare being less than one in a million, and no specimen other than the one mentioned could be found during the last three years.

With a view to explain the abnormality, a histological study was attempted. The epidermal cells at the tip of the normal gynophores (Fig. 2) are found to contain many round bodies—plastids. There are as many as 5–20 bodies in each of the cells at the tip. The number of the bodies gradually decreases away from the tip. They are round and 1 μ to 4 μ across. In specimens fixed in formalin-acetic alcohol, and stained with Haidenhain's hæmatoxylin, the plastids are

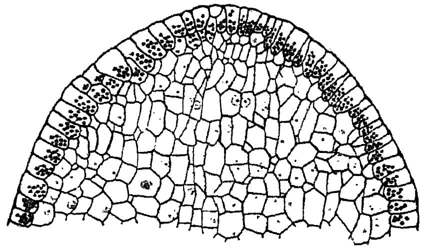

Fig. 2.

Longitudinal section of positive geotropic gynophore with numerous dark bodies in the epidermal cells. ×120.

seen as dark bodies almost filling the upper part of the cell cavity (in sections 10 μ thick) (Fig. 2). But in the abnormal pegs, the plastids are comparatively few or wanting (Fig. 3). When present they appear shrunken and much smaller than the normal.

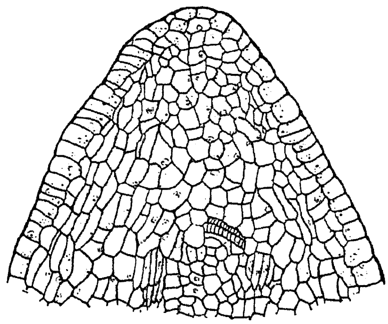

Fig. 3.

Longitudinal section of negatively geotropic gynophore with a few disintegrating bodies in the epidermal cells. ×120.

Waldron, R. A. (1919) while recognising the effect of gravity in bringing about the downward growth of the gynophore, considers that "the presence of definite granules in the lumen of each of the epidermal cells of the gynophore at the tip and their absence anywhere else suggest the possibility of such being the structures by which the organ perceives when it is out of line with gravity". He had, however, no opportunity to study the behaviour of negatively geotropic gynophores.

The effect of gravity alone is not the immediate, decisive factor in bringing about the downward growth or positive geotropic movement of the normal peg. Because in spite of gravity some of the pegs changed the direction of growth, there must be a cause more directly responsible. From the

abundance of the plastids in the normal pegs and their scantiness in the abnormal ones, it may be inferred that these bodies or the organs of perception that respond to gravity and bring about positive geotropic movement. The plastids appear first after fertilisation. If they are not formed at that time, the peg grows quite erect. In some pegs, the number and the size of the plastids get diminished, or they might disintegrate, after a period of normal growth; and then the peg curves upwards and becomes negatively geotropic. The function of the plastids is not analogous to that of the freely moving starch grains in certain grass roots, where they are said to bring about curvatures due to internal excitement set up by them (Statolith theory of geotropism). Unlike the starch grains, the plastids are confined to the upper part of the lumen of the cell. Their exact nature and the reason why after a period of normal functioning, they become affected and functionless, in certain rare instances, are not known; further study is expected to throw light on this very interesting subject.

The abnormal pegs did not produce any pods and seeds possibly for want of medium of sufficient resistance. In a set of experiments conducted in the Oil Seeds Section, the developing gynophores were made to enter artificially made up media. For this bamboo tubes about six inches long and about an inch in diameter and having a node septum at one end to act as bottom, were filled each with wet and dry, ordinary soil, stiff clay, sterilised sand, powdered wood charcoal, saw dust, cotton wool and also water separately. Empty tubes, dry and moist, were also set up. The tubes were buried in the soil to keep them in position and were covered with circular paraffined straw boards to make the tubes dark inside. Small perforations just to allow the passage of the gynophore were provided. Pods developed uniformly in the soil, clay and powdered charcoal irrespective of the medium being moist or dry; but pods did not form in the other media, *viz.*, saw dust, cotton wool and air, possibly for want of sufficient resistance.

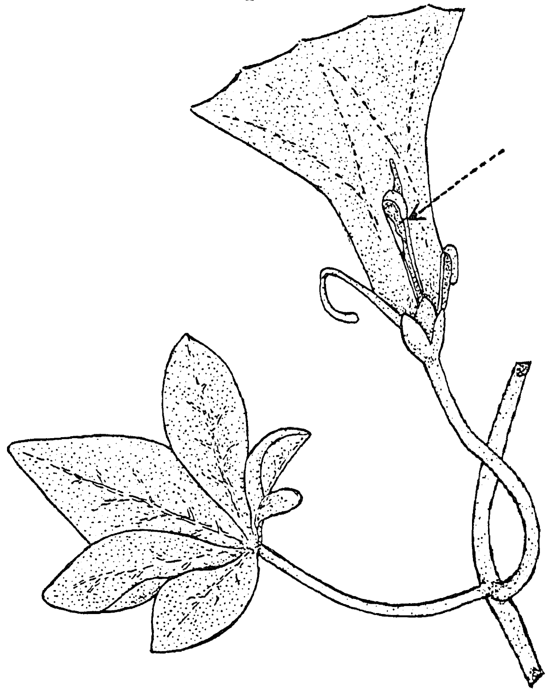
Duplicate Corolla in *Ipomœa palmata* Forsk.

Ipomœa palmata Forsk is a common garden convolvulus in Bombay. Ordinarily its flowers have a single infundibuliform corolla.

Recently, a plant of this species has been observed putting forth flowers which bear five additional free petaloid structures about



3 cm. long and 0·5 cm. broad, arising outside and jointly with the base of the corolla. The facing of this new whorl is inside out.

This additional development in a large number of flowers on a single plant is worth registering.

Studies in the Development of the Pollen Grain and Embryo Sac of *Wolffia arrhiza*.

THIS interesting plant—the smallest angiosperm known—is seldom seen flowering. In November, 1933, the writer found it flowering abundantly near Agra. A study of the development of the gametophytes revealed several important differences from those of *Lemna minor* (Caldwell, 1899).[1]

Microsporogenesis and Male gametophyte.—The stamen, in early stages, consists of a very short filament and a spherical anther containing a mass of homogeneous cells

covered over by the epidermis. Soon a sterile plate of cells running vertically divides this mass into two so that by the time the peripheral archesporial cells cut off the primary parietal layer, the microspore mother-cells are seen in two distinct groups and the anther becomes bilobed in outline (Fig. 1). The primary parietal layer divides to form the endothecium and the tapetum (Fig. 1); there is no middle layer whatever. At maturity the cells of the endothecium enlarge and develop the usual fibrous thickenings while the epidermal cells degenerate and are sloughed off.

The tapetal cells, which remain only one-nucleate, become amœboid and project into the loculus (Fig. 2). The reduction divisions in the microspore mother-cells are successive, but a few cells lying towards the periphery do not undergo any divisions and degenerate.

In the pollen grain the generative nucleus is at first organised into a small lenticular cell separated from the large tube cell by a narrow space. Later, the generative nucleus becomes free though still surrounded by a cytoplasmic sheath. At this stage the periplasmodium is about to disappear completely and so is the sterile partition between the two lobes. The mature pollen grain is three-nucleate and the tube nucleus shows a degenerated appearance (Fig. 3).

The dehiscence of the anther is rather interesting. About the time when the pollen grains are 2-nucleate, the cells of the endothecium lying just over the sterile partition (at *x* in Fig. 4) presents a degenerated appearance and do not show the usual fibrous thickenings—these cells facilitate the opening of the anther (Fig. 5). At this stage the sterile plate of cells separating the two loculi also disappears and the two halves of the endothecial coverings curve outwards and downwards exposing the entire mass of pollen grains for dissemination (Fig. 6).

Megasporogenesis and Female gametophyte.—The nucellus in the early stages consists of only a few cells—the hypodermal archesporial cell usually surrounded by one layer of cells. This cell cuts off the primary parietal cell which undergoes one or two anticlinal divisions (Fig. 7). The megaspore mother-cell enlarges considerably destroying the whole of the nucellus except the two layers of cells at the top, so that the lateral sides of the subsequently formed embryo sac lie immediately adjacent to the inner integument. The megaspore mother-cell divides into two cells of which the upper degenerates while the lower, after 3 successive divisions of its nucleus, forms the normal eight-nucleate embryo sac (Figs. 8–9). Thus the development of the female gametophyte is of the "*Scilla type*" while in *Lemna*, Caldwell

(1899) reported this to be of the "*Lilium type*". The antipodals are ephemeral and the polars fuse early (Fig. 9).

The ovule remains orthotropous throughout its development. Of the two integuments, the outer begins to develop only after the megaspore mother-cell has undergone one division. The carpel shows a clear stylar canal extending throughout its length. Further investigation on the development of the endosperm and embryo is in progress.

I am greatly indebted to Dr. P. Maheshwari for his kind help and valuable suggestions.

A Note on the Chromosome Numbers of Some Eleusine Species.

N. S. RAU[1] (1929) considered 36 as the probable diploid number in the root-tips of *E. coracana* Gaertn. Avdulov[2] (1931) has determined 18 and 36 to be the diploid numbers in Eleusine and suggests 9 or 10 to be the basic number of the tribe *chlorideæ*. Hunter[3] (1934) confirms the number 36 for *E. coracana* obtained by Avdulov.

The present investigation was taken up to determine the chromosome numbers in some of the local Eleusines. The following species, collected at Coimbatore, were studied :—*E. coracana*, Gaertn.; *E. indica*, Gaertn.; *E. brevifolia*, Br.; *E. ægyptiaca*, Desf. Flower buds were killed between 10-11 A.M. in the following fixatives: Carnoy's, Allan's modification of Bouin's and Flemming's (weak). Sections were cut at 10-12 μ and stained in hæmatoxylin and also gentian violet iodine.

The haploid chromosome numbers were determined in metaphase plates and at diakinesis as follows :—*E. indica*—9 ; *E. coracana*—18 ; *E. brevifolia*—18 ; and *E. ægyptiaca*—17. Secondary pairing was noticed in the last three species. It is evident that *E. indica* is a diploid, *E. coracana* and *brevifolia* are tetraploids, while *E. ægyptiaca* is probably a tetraploid with one pair lost ($4x-2$). The basic number is, obviously, 9.

Two New Host-Plants of *Loranthus* at Allahabad.

THE partial parasite *Loranthus* commonly grows in the Upper Gangetic plain on a number of host-plants belonging to different families of the Dicotyledoneæ. They are especially found on trees or shrubs, the commonest hosts being *Mangifera indica* and *Bassia latifolia* (Duthie,[1] Brandis[2]).

In January 1935, the author observed this parasite growing on a guava (*Psidium Guayava*) tree, which was an unfamiliar sight. No other plant in the vicinity, but a number of guava trees in an orchard about 2 miles off, had *Loranthus* on them. On looking up the literature on the subject,

Fig. 1. *Loranthus longiflorus* on *Psidium Guayava*.

Fig. 2. *Loranthus* sp. on *Citrus medica* var. *acida*.

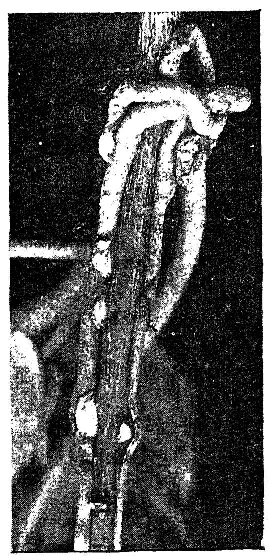

Fig. 3. The same as Fig. 2. showing the secondary roots and haustoria of the parasite.

no mention of *Psidium Guayava* as a host of *Loranthus longiflorus* was found.

A knob was, as usual, formed at the junction of the parasite and the host (Fig. 1). The parasite produced a number of branches with glabrous and somewhat leathery leaves. Flowers and fruits were present. The parasite was *Loranthus longiflorus* Desr. which is the commonest species in the United Provinces.

Psidium Guayava is a non-indigenous plant of the family Myrtaceæ with bark composed of dry membranous layers but now it is naturalised throughout India (Hooker[3]).

Scott[4] and Bidie[5] are of opinion that plants having deciduous bark with dry membranous layers are unfavourable hosts of this parasite.

Fischer[6] dissents from the above view and has mentioned in his list, a number of plants attacked regularly by the parasite, which have similar characters of the bark, but very few plants of the family Myrtaceæ, especially the non-indigenous genera, are recorded by him as host-plants.

Patwardhan[7] noted *Eucalyptus rostra*, a non-indigenous plant as a host of *Loranthus longiflorus* in Poona. Kamerling[8] mentions *Loranthus dichrous*, a species not found in India, on *Psidium Guayava* in Brazil.

Later on, sometime in the middle of February, the parasite was seen growing on another new host-plant, *viz.*, *Citrus medica* var. *acida* (Fig. 2). The primary root was not seen at that stage. A number of secondary roots were seen arising at the point of infection which was the junction of the host and parasite. A knob-like structure was formed at this point. These roots grew outwards and spread over the surface of the host-plant, coiling round in every direction and sending out the haustoria into the tissues of the host to absorb the necessary nourishment (Fig. 3). The roots vary in size and length with age. Some of these were fairly thick and brown with a number of lenticles on them, others were thin and green in colour, with conical growing tips. From these spreading roots, erect branches bearing a number of foliage leaves were developed. By means of these secondary roots the infection is spread over the surface of the host-plant. These roots were not sensitive to gravity as they seemed to be going up or down the branch indiscriminately. The bark of the host-plant was fairly thick.

Fischer[6] in his list mentions *Citrus medica* as a host for *Loranthus neelgherrensis* and another species (not named) of *Citrus* attacked by *Loranthus elasticus* in Southern India. Both of these species of the parasite are not found in Northern India.

I am to express my great indebtedness and sincere thanks to Prof. J. H. Mitter for his kind suggestion and advice. Thanks are also due to Mr. Anil Mitra, for preparing photographs.

A Note on a Comparative Study of the Chromosomes in Ten Species of Indian Dragonflies.

LEFEVRE AND MCGILL[1] as co-workers (1908), Smith[2] (1916) and Oguma[3] (1930) are the only authors who so far have devoted their attention to the chromosome studies in this very ancient family of insects. In a paper published by Oguma and Asana[4] (1932) attention was drawn to a very interesting observation, whose significance is not yet quite clear, that the so-called *m*-chromosome (the smallest among the autosomes) presents every grade of size reduction among the testicular cells of a single individual belonging to a species of *Odonata*, *Tramea chinensis*, collected in the vicinity of the Gujarat College, Ahmedabad, Western India.

This rather remarkable observation led us to make a comparative study of the chromosomes in the male germ cells of some ten species of Indian dragonflies so far collected, from a very restricted area situated in the neighbourhood of the Ismail College, Jogeshwari, about 20 miles north of Bombay. The following observations are based on the species listed below.

May we take this opportunity to express our thanks to Colonel F. C. Frazer who very

kindly identified the species for us. A short account of our observations on the chromosome numbers, the X-chromosome and the *m*-chromosome of these Indian species of dragonflies is given below:

Species	Haploid	Diploid
Sub-Order Anisoptera		
Sub-family Libelluniæ		
1. *Pantala flavescens* ..	13	25
2. *Tramea limbata*	13	25
3. *Trithemis palladinervis* ..	13	25
4. *Diplacodes trivialis* ..	13	25
5. *Brachythemis contaminata* ..	13	25
6. *Crocothemis servilia* ..	13	25
7. *Potamarcha obscura* ..	13	25
8. *Orthetrum sabina*	13	25
Aeschininæ		
9. *Ictinus rapax*	12	23
Sub-Order Zygoptera		
Family Coenagrionidæ		
10. *Ceriagrion rubiæ*	14	27

As will be seen from the above table, all the members of Libelluniæ show a constancy in the number of chromosomes, 25 in diploid and 13 in haploid. In *Ictinus* which belongs to another group, Aeschininæ, the diploid is 23, the haploid 12. The chromosome number in *Ceriagrion* (Coenagrionidæ), whose chromosomes have been studied for the first time, the number is the largest among all the dragonflies studied so far.

Despite the variation in the chromosome number, there is present an unpaired X-chromosome, without exception, in all the species investigated. In every case, the X-chromosome always takes a peripheral position on the outer circle of the spindle both in the spermatogonial and primary spermatocyte metaphases and acquires a peculiar eccentric position in the metaphase of the secondary spermatocyte. And a special emphasis may be laid on the fact that it separates into two equal halves in the primary spermatocyte division, but migrates to one pole entire without separation, ahead of other chromosomes, in the second spermatocyte division.

However, regarding its size or magnitude in relation to other chromosomes it does not show a uniform behaviour in all the ten species studied. Taking first all the species of Libelluniæ, the X-chromosome in all of them looks nearly, though not exactly, equal in magnitude to the second smallest autosome univalent in the spermatogonial complex. While in *Ictinus rapax* (Aeschininæ), it is interesting to note, the X-chromosome stands as the largest element in its chromosomal complex. It is remarkably large and occupies a central position in the spermatogonial metaphase. In *Ceriagrion rubiæ*, a representative of our third group, Coenagrionidæ, the X-element, in its size relation to other members of the complex, resembles the X-chromosome in the species of Libelluniæ.

Finally, throughout all these Indian species of dragonflies the smallest autosome, the so-called *m*-chromosome, is present without exception. And it is a remarkable fact that the relative magnitude of this *m*-chromosome to that of the X-element varies from species to species.

A full account of these observations will be published elsewhere.

Madras Fisheries Department.

Two serious misapprehensions on the part of the reviewer of my report on the Madras Fisheries Department for 1933–34 in the June number of the *Current Science* call for remarks :—

Hilsa.—The reviewer states, "The Department's efforts to introduce *Hilsa* along the west coast are not likely to meet with success as there are no large rivers in that area for fish to run up for spawning purposes." There is nothing in the report to lead the reviewer to believe that the Department is making such efforts. More than 25 years ago the late Mr. Wilson made a solitary experiment of planting some *Hilsa* eggs in the Ponnani river. This was never repeated as the unsuitable nature of the west coast

rivers for the breeding of *Hilsa* was recognised years ago by the Department.

Catla.—Regarding the introduction of *Catla* in the Cauvery the reviewer has misunderstood the scope and aim of the Department's operations. He remarks as follows: "It is doubtful, however, whether any good can result from the stocking of the upper waters of the Cauvery because the fish is not adapted to live in clear rapid running water." The "upper reaches" referred to is the section of the Cauvery river above the Mettur Dam up to the Hoginkal falls (now the Mettur reservoir) and the reach immediately below the Dam. The reviewer is wrong in assuming that *Catla*—which is "a tank fish" in the sense that it enters tanks for feeding and growth—does not live in rivers. Our studies of the habits of *Catla* as well as experience in its culture in South India for the last 20 years prove beyond doubt that *Catla* will not breed in the stagnant water of tanks and ponds like some other carp though they grow and thrive in them, but require a river or stream of running water for breeding. The experience of culturists elsewhere in India has been the same. A striking evidence of this—if proof is needed—is found in the occurrence of *Catla* in the Cuddapah and Nellore Districts, only where the tanks and rivers (the Pennar river system) are directly connected by the Cuddapah-Kurnool canal with the upper waters of the Kistna (Tungabhadra) in this Presidency. Soon after this canal was opened, *Catla* began to appear in the Pennar river and connected tanks in the Cuddapah and Nellore Districts where it was unknown before.

The reviewer may rest assured that the Madras Fisheries Department does pay some regard to the ecology of fish that are subjected to artificial cultivation.

B. SUNDARA RAJ.

Madras Fisheries Bureau,
July 11, 1935.

IN the above note attention is drawn to two supposed "serious misrepresentations" on my part. In my review I represented the Madras Fisheries Department as making efforts to introduce *Hilsa* along the west coast and of stocking the clear rapid-running waters of the Cauvery with *Catla*. At the very outset, it may be stated that I had no intention of running down the work of the Madras Fisheries Department or of minimising the splendid efforts that are being made in that province in connection with the improvement of fisheries.

The title of my review—"Madras Fisheries Department"—is partly suggestive of the scope of my remarks. For the purpose of an adequate review of the last report of the Department, I read several earlier reports and the impressions I gained from this study are embodied in my comments on the work of the Department. In order to follow my remarks about *Hilsa* and *Catla*, the readers are, therefore, advised to study the relevant parts of the earlier reports of the Department as well.

It is a great relief to learn now for the first time that the experiments started by the Department about the introduction of *Hilsa* along the west coast are not being repeated. Regarding *Catla*, however, the position is somewhat different. In the report for 1930–31 (para. 144, p. 44) it is stated that "*Catla* has been stocked in upper waters of the Cauvery first below the Hoginkal falls and later at Mettur above the dam." My submission is that pools below waterfalls are not suitable for stocking fishes of the *Catla* type, which is essentially a fish of sluggish waters, such as ponds, tanks, large rivers, etc. Moreover, the description of the stream below the falls shows that it consists of rapids, and, if this is really so, the fish has no chance to live and flourish as *Catla* is not adapted for life in swift currents. My assumption is borne out by the results obtained by the Madras Fisheries Department which has been stocking with *Catla* the Cauvery below the falls for a period of several years but has not obtained any definite proof so far that the fish has established itself in these waters. With the formation of the "Mettur reservoir" the results may be different.

What is stated in the above note regarding the ecology and bionomics of *Catla* is elementary knowledge for people of northern India. *Catla* breeds during monsoon floods when it gets an opportunity to leave its permanent abode and enters shallow, warm waters of paddy fields, etc. So far as my information goes, it does not breed in rivers but in the flooded country adjoining them.

REVIEWER OF THE REPORT.

Dairy Science.*

MILK is the most important food of man and beast and in the early stages of their life, offers the only source of nutriment ensuring steady maintenance and growth, building up immunity against disease and laying the foundations of the future health of the individual. The constituents of milk, proteins, sugars, fats, pigments and minerals are so well-proportioned as to render this product one of the most easily digestible and highly assimilable of all foods. These unique properties and its indispensability in the nutrition of animals, have been responsible for stimulating a vast amount of research on the physical, colloidal, chemical, bacteriological and nutritional aspects of milk.

The recent publication entitled *Fundamentals of Dairy Science*, is devoted to a discussion of these fundamental questions and provides detailed and authoritative information on these various aspects from a purely scientific point of view.

The first five chapters deal with the chemical composition of milk and milk products, and proteins, fat and carbohydrates comprising the essential constituents of milk. An entire chapter has been devoted to an able review on the pigments of milk which have assumed great importance in relation to vitamins and respiratory enzymes.

Milk furnishes one of the finest examples of a typical and perhaps a comprehensive colloid, several phases of varying degrees of dispersion, participating in the system. A beautiful discussion of this colloidal aspect is to be found in the chapter on the physical equilibria of milk. The sizes of particles which were wrongly expressed in the previous edition have now been corrected and the conventional and generally accepted unit, $m\mu$, adopted.

Many of the physical and chemical properties of milk, which are of great importance from an industrial point of view, have been discussed in relation to certain processes in the dairy industry. The creaming ability of milk has been correlated with the state of aggregation of the fat globules and the effect of several industrial treatments like pasteurisation, homogenisation, etc., on creaming has been discussed from the fundamental standpoint. In a similar manner, the quality of foaming, cream-whipping and coagulation in relation to cheese manufacture, which is one of the most important of dairy industries, have been treated.

Milk is an excellent culture medium for the growth of various types of micro-organisms including many bacteria pathogenic to man, and the large-scale production, handling and transportation of such a product, therefore, present problems in pasteurisation, maintenance of sterility etc., involving a rigorous bacteriological control, which is facilitated by a close understanding of the ecology of the bacterial associates, their multiplication and growth in relation to the physical and chemical properties of milk. These problems are presented in the series of chapters devoted to a discussion of the microbiology of milk and milk products.

The last two chapters provide information of great interest not only to the physiological chemist but also to the general reader. The nutritional value of milk in the early and later stages of the life of an animal, is discussed in relation to other sources of nutriment. Attention is drawn to the incidence of nutritional anæmia due to the low content of iron and copper in milk, constituents found essential for the regeneration of hæmoglobin. Vitamin constituents of milk in relation to breeds and feeds are discussed.

The rôle of colostrum in the nutrition and immunisation of infants and young ones has been the subject of controversy and a useful discussion of this vital subject which is presented in the volume is helpful to those investigators interested in this aspect of milk nutrition.

Most of the valuable information contained in the volume relates naturally to cow's milk which is the most important dairy animal in the world; but there are other animals like the buffalo and the goat which are the main, if not exclusive, sources of milk to certain races and communities. Buffalo's milk in particular deserves a more detailed treatment since it is often a more economical dairy animal yielding a richer quality and larger quantity of milk. Data giving a comparative idea of the nutritive values of milks from various milch animals would form a most useful addition to this chapter on the nutritional value of milk.

This monograph is perhaps the only treatise in the English language which deals in a comprehensive manner with the several aspects of dairy science. It is a volume

* *Fundamentals of Dairy Science*, by Associates of ore A. Rogers, Reinhold Publishing Corporation, New York, Second Edition, 1935, pp. 616, $ 6.

which will be gratefully welcomed not only by a number of specialist investigators, the colloid chemist, the biochemist, the physiologist and the bacteriologist, but also by dairy technologists, physicians and food-chemists, interested in the relation of milk to public health and nutrition.

(MISS) K. BHAGVAT.
M. SREENIVASAYA.

The Arachnida.*

SINCE Warburton's article in the *Cambridge Natural History* which appeared as far back as in 1909, no complete account of Arachnida in the English language existed and the present monograph fills a gap in our knowledge of Arthropods.

In the prolegomena considerations like the general characteristics, habits and behaviour and the evolution and classification of the class have been dealt with. Our knowledge regarding many of these problems is by no means complete, but the author, including most of the recent literature on the subject, has made it as up-to-date as possible. Buxton's extensive researches on the coxal glands of arachnids and Millot's investigations into the anatomy and physiology of many arachnids have been incorporated. A consideration of the evolution of the class is not a matter of ease. Conflicting theories like those of Ray Lankester and Pocock, of Zittel and of Leukart, Hansen and Sorensen have made the problem a very difficult tangle from which only a few very clear features emerge. The Trilobita, the Eurypterida and Limulus centre round this problem, and the question ultimately resolves itself to a matter of assigning importance to the fossil remains of the Eurypterida and the Trilobita, and the few forms that stand intermediate between these and Limulus. It need hardly be emphasised that the ancestry of arachnids is closely bound up with the question of the primitive habitat of arachnids and there is no doubt that, should the theory of Leukart, Hansen and Sorensen come to be accepted, there should have to be a complete change in the interpretation of the diverse characters presented by the arachnids. But it is more likely that, if there is one group of animals that will shed more light on this vexed question, it is the Onychophora.

Nor has the classification of the Arachnida been free from changes and this is mainly due to the indiscriminate distribution of many anatomical features among the different orders. The Arachnida, therefore, cannot be divided into orders which can be arranged in an ascending series. A number of schemes of classification have been examined by the author who finally adopts Pocock's scheme, with this alteration, that he excludes the Trilobita from the Arachnida on the ground that they are primitive Crustacea.

The Xiphosura has been treated with a thoroughness which it richly deserves. The only group of primitive arachnids which is surviving to this day, it also includes the only marine forms. A chapter is devoted to each of the other orders, whose anatomy, distribution, classification and diagnostic features are described. Of these the Recinulei stand out with great prominence. This group of arachnids whose rarity is great and whose importance is hardly less, seems to be the only one where the animals possess no type of sense organ and carry their genitalia in their tarsi. Only 32 living specimens are known and as the author says "the future of this group may well hold surprises in store".

Two chapters are devoted to extinct arachnids, of which the Eurypterida are the most important. The position of the Trilobita is also discussed, the author being definitely of opinion that they are primitive Crustacea.

Our knowledge of the Pycnogonida, Tardigrada and Linguatelida has not advanced further after the article by Warburton in the *Cambridge Natural History* and even in 1935 the author of a treatise on Arachnida has to treat them as "doubtful arachnids". The Tardigrada have the least justification for inclusion amongst the arachnids.

But for Mr. Savory's long chapter on economic arachnology, one would have thought that these animals were of no economic importance. He has given a variety of ways in which the Arachnida influence the lives of men. The ticks and mites, the spiders

* *The Arachnida.* By Theodore H. Savory. Pp. xi+218, 8 Plates. (London: Edward Arnold & Co. 1935.) 25 *sh.* net.

and scorpions and even Limulus seem to contribute to this importance.

In a work on the Arachnida and for that matter, on any Arthropod class it is impossible to avoid extensive classification and the monotony of this has been successfully dispelled by the "excursus" which the author appends to every chapter. Many of these are full of interest to the layman, and all to the naturalist. In one, on "The Arachnida as formidable animals" (page 113), the author discusses the psychology of fear and accounts for the terror that spiders and scorpions infuse in our minds as due to the rapid movements that these animals exhibit. While granting that rapidity of movement is one of the contributory causes of fear, it should be said that it is only one of the causes. Nor is it a reason in all cases of fear. A swiftly darting bird does not infuse terror and after all, a dead scorpion induces fear just as much as a moving, very much alive one. Several other topics of general interest are dealt with in these little essays and the book closes with a full bibliography and a complete index.

Functions and Organisation of the India Meteorological Department.*

IN an interesting pamphlet entitled "Functions and Organisation of the India Meteorological Department, 1935," the Meteorological Office, Poona, has summarised the various functions of the Department and has described briefly the organisation that exists at present for carrying on these duties. The list is comprehensive and contains all the important phases of the work usually dealt with by similar institutions in other progressive countries. Increasing attention has, of late, been given to the problems of upper air, chiefly owing to their importance in connection with aviation; but it is admitted that the meteorological service for this purpose still falls short of the minimum recommended by the International Convention.

Besides meteorology, the activities of the Department include some branches of allied sciences such as seismology and terrestrial magnetism. Thus geophysical researches form part of the routine duties at the Colaba and Alibag Observatories while the Observatory at Kodaikanal, South India, specialises in the study of solar physics and has undertaken some work in co-operation with the International Astronomical Union. Mention is made also of the seismographs that have been maintained at a few stations for the systematic recording of earthquakes.

It is interesting to note that a section for agricultural meteorology has been recently established at the headquarters of the Department, at the Instance of the Imperial Council of Agricultural research. Besides statistical investigations, the section makes a special study of microclimatology and generally carries on researches on problems affecting the welfare of the crops. In view of the supreme importance of this branch of the subject to an agricultural country like India the results of these investigations will ultimately prove to be of considerable practical value. A brief outline is also given of some features of the developments that are contemplated as soon as financial conditions permit; and the note concludes with four appendices giving extracts relating to meteorology from the proceedings of International Conventions and the Royal Commission on Agriculture in India.

* Functions and Organisation of the India Meteorological Department. 1935. Meteorological Office, Poona.

The Indore Meeting of the Science Congress.

ARRANGEMENTS are now actively in hand for the forthcoming meeting of the Indian Science Congress Association in Indore. As usual, the date of the meeting is from the 2nd to the 8th of January, 1935, thus enabling members to avail themselves of the Christmas concession on the railways. In addition, the railway authorities have been approached with regard to granting further concessions, but their decision in the matter will not be known until after the Railway Association has met at Simla in October.

The meeting is being held under the patronage of H. H. Maharajadhiraj Raj Rajeshwar Sawai Shree Yeshwant Rao Holkar Bahadur, Maharaja of Indore. In accordance with the alteration which was made last year in regard to the President's term of office, Dr. J. H. Hutton will remain President of the Association until he hands over his office at the Inaugural Meeting to the President-Elect, who is Rai Sir Upendranath Brahmachari, Bahadur, Kt., M.A., M.D., Ph.D., F.S.M.F., F.A.S.B.

At the last meeting of the Congress, held in Calcutta, two alterations were made in the list of Sections. The name of the Geology Section was changed to "Geology and Geography," thus indicating that papers on geography would be accepted; while a new section for Physiology was added, thus bringing the number of Sections upto 10.

The names and addresses of the Sectional Presidents are as follows:—

1. *Mathematics and Physics.*—Dr. T. Royds, D.Sc., Director, Kodaikanal Observatory, Kodaikanal, S. India.

2. *Chemistry.*—Dr. P. C. Guha, D.Sc., Professor of Organic Chemistry, Indian Institute of Science, Bangalore.
3. *Geology and Geography.*—B. Rama Rao, Esq., M.A., Mysore Geological Department, Bangalore.
4. *Botany.*—Dr. S. R. Bose, D.Sc., F.R.S.E., F.L.S., Professor of Botany, Carmichæl Medical College, Belgachia, Calcutta.
5. *Zoology.*—Dr. H. K. Mukherjee, D.Sc., D.I.C., University Professor and Head of the Department of Zoology, Calcutta University, 35, Ballygunge Circular Road, Calcutta.
6. *Anthropology.*—H. C. Chakladar, Esq., M.A., Lecturer in Anthropology, Calcutta University, 28-4, Srimohan Lane, Kalighat, Calcutta.
7. *Agriculture.*—Mr. A. K. Yegna Narayan Aiyer, M.A., Dip. in Agri. (Cantab.), N.D.D., F.C.S., Retired Director of Agriculture, Sankarapuram, Bangalore.
8. *Medical and Veterinary Research.*—Lt.-Col. H. E. Shortt, I.M.S., Director, King Institute, Guindy, Madras.
9. *Physiology.*—Dr. W. Burridge, D.M., M.A. (Oxon.). Professor of Physiology, University of Lucknow, Lucknow.
10. *Psychology.*—J. M. Sen, Esq., M.Ed. (Leeds), B.Sc. (Cal.), F.R.G.S., Inspector of Schools, Presidency Division, Bengal, 63, Lansdowne Road, Calcutta.

Papers should be submitted to the Sectional Presidents concerned by the 15th of September. A little extra time will be allowed to contributors in the Punjab.

One of the primary purposes of the Association is to encourage scientific work in different parts of India. This year it is meeting in Indore for the first time, and it is hoped that a large number of members will attend and help to stimulate scientific research in that part of India.

Indore, in addition to being fairly centrally situated for scientists from Western and North-western India, offers many attractions both in the City itself and in its immediate neighbourhood. Owing its origin to the great movement for Mahratta imperialist expansion of the 18th century, Indore at present enjoys the premier position among the States included in the Central India Agency.

The City of Indore is situated 1,738 feet above the sea-level and has a delightful climate and moderate rainfall. It ranks amongst the great industrial towns of India, having flourishing cotton-mills and an expanding population now estimated at about 1,50,000 people. It is an important educational centre, containing two first-grade colleges (one of which is maintained by the State), a number of high schools for boys and girls and other institutions. In the Civil Area are situated the Daly College (an institution for the sons of Chiefs), which is a fine building of white marble, the Plant Institute, and a Medical School. Indore also contains many places and buildings worth seeing. A few miles from the City is Badarkha, where up-to-date water works (with the largest siphon system in the world) are nearing completion.

About 60 miles from Indore and situated in Dhar State is Mandu, a favourite haunt of tourists and students of India's past history. Once the proud capital of the independent Muslim kingdom of Malwa and a fort of unparalleled natural strength, it now contains extensive ruins of mosques, palaces and other buildings of great architectural merit. Not far off from it is Bagh (in Gwalior State), which is famous for its rock-cut caves of great antiquity. About forty miles to the south of Indore is Mandhata, an island of superb natural beauty in the Nerbudda river, the early capital of Indore State, which contains a palace and a marble statue of the saintly Ahilya Bai, one of the most illustrious rulers of the State and of India. Not very far off from Indore and easily connected by railway are Ujjain, one of the most ancient and sacred cities of India, Sanchi (in Bhopal State) with its famous stupa supposed to date from the time of the great Asoka, Chitore the most historic place in Rajputana, and the world-celebrated Ajanta caves.

The Local Secretaries will be Dr. S. S. Deshpande, Vice-Principal and Professor of Chemistry, Holkar College, Indore, and Mr. K. A. Patwardhan, Daly College, Indore, to whom all enquiries as to accommodation should be addressed. It is particularly requested that very early intimation of the accommodation required should be sent to the Local Secretaries.

W. D. WEST.

Sir Richard Arman Gregory, Bt., F.R.S. and Dr. Arnold Berliner, Dr.Phil.

WE are glad to announce that Sir Richard Gregory and Dr. Arnold Berliner have accepted our invitation to act as Associate Editors of *Current Science*, and we have no doubt that this news will give widespread satisfaction among those interested in the progress of the Journal.

We have had the privilege of meeting Sir Richard and Lady Gregory during their visit to this country in January and February of 1933 and of discussing with him about the affairs connected with *Current Science*. We need hardly say that we are deeply indebted to him for the numerous suggestions which he offered at the time, and since his return to England, he has maintained his interest in this Journal.

Dr. Arnold Berliner has not visited India but we hope that he will be able to come over at an early date and spend a pleasant time among his numerous friends in this country. We would be glad to offer welcome to him on behalf of our numerous readers and there will always be generous hospitality for him in this country.

The service which Sir Richard Gregory and Dr. Arnold Berliner are rendering to the cause of Science is indeed conspicuous. Their association with their respective Journals during the past thirty years or more has rendered the publications unique. To every Scientist *Nature* and *Naturwissenschaften* are as familiar and indispensable as the objects by which they are surrounded in their Laboratory. Their knowledge and experience will be of great assistance to us in shaping the destiny of *Current Science* and when this assistance is coupled with the advice and co-operation for which we are always indebted to the members of the Board of Co-operators, *Current Science* is bound to become the Indian counterpart of *Nature* and *Naturwissenschaften*,

Research Notes.

Effect of Simultaneous Electric and Magnetic Fields on Spectral Lines. I. Crossed Fields.

A STUDY of the effect of magnetic fields (Zeeman Effect) and of electric fields (Stark Effect) has been a guiding adjunct in the classification of spectral lines and the theoretical investigations of these effects have been of fundamental importance in the development of Quantum Principles. The simultaneous effect of magnetic and electric fields on spectral lines has now been investigated by W. Steubing and the results are reported in the *Sitzb. d. Preuss. Akad. d. Wiss. Berlin*, 1935, p. 3. We shall here summarise the effect observed when the magnetic and electric fields are perpendicular to each other. In every case the pattern due to the electric field is altered by the introduction of the magnetic field. The following regularities have been observed :

(*a*) The *p*-components of the electric field are affected.

(*b*) Such series lines as have a large Stark effect are very sensitive to the magnetic field while those that show small Stark splitting exhibit only a Zeeman effect. However, the separation produced is sometimes larger and sometimes smaller than that due to the normal Zeeman effect. The variation from one series to another is more than double for the same electric and magnetic fields.

(*c*) The lines of the sharp series, so far at least as the first members are concerned, separate as in the pure Zeeman effect, apart from an alteration in the intensities of the components. Similarly the lines due to forbidden combinations which appear under the electric field show only the Zeeman effect. The effect on the principal series is intermediate between that on the sharp series and the effect observed in the diffuse series.

(*d*) In the case of the diffuse series, the number of components produced by the electric field remains unaltered, but the lines broaden out asymmetrically, so that those on the longer wavelength side widen towards the red while the lines on the shorter wavelength side broaden towards the violet. These widened bands have no structure. The bands have a sharp edge on one side and trail off on the other side and have a width about five times the maximum Zeeman separation of the same line.

(*e*) Both in the diffuse series and in the principal series, the broadening increases with the total quantum number. The inner components are less broadened than the outer.

(*f*) The crossing of the fields does not give rise to any new lines.

(*g*) The effect of a magnetic field below 10,000 oersteds is small, but above 20,000 oersteds its effect is more marked than that due to an electric field of 100,000 volts per centimetre.

T. S. S.

The Ferromagnetism of Gadolinium.

THE only known ferromagnetic elements were until recently iron, nickel and cobalt but now another has been added to the family thanks to the labours of G. Urbain, P. Weiss and F. Trombe (*Comptes Rendus*, 1935, **200**, 2132). This new member of the ferromagnetic group is the rare earth metal Gadolinium recently isolated in great purity by F. Trombe. The only impurities were 0·7% of silicon and 0·03% of iron. Small quantities of this precious metal had to be employed and the methods developed at Strasbourg for handling quantities of the order of 0·12 grm. were found most serviceable. Gadolinium was found to be even more ferromagnetic than iron but only at low temperatures. Its Curie point above which the ferromagnetic character is lost happens to be $16° \pm 2°$ C. so that it is only at low temperatures that its ferromagnetic character would be displayed. The specific magnetisation σ varies with the field according to the equation $\sigma_H = \sigma_\infty (1 - a/H)$ and its behaviour from the boiling point of liquid nitrogen, *viz.*, 77° K. to the Curie point shows its great magnetic reluctance, for the constant a in the above equation has the value 1250 while for iron it is below 10. At 77° K., however, its specific magnetisation reaches a larger value than that for iron beyond about 15000 gausses. The absolute saturation value calculated from a T^2-law which is found to hold even below 77° K. comes out to be 253·5 C.G.S. units while for iron it is 221·7. The atomic moment of Gadolinium is 35·4 Weiss magnetons while it is only 11 Weiss magnetons in the case of iron.

T. S. S.

The Growth of Crystals.

ALTHOUGH a considerable amount of information has been accumulated on the nature and constitution of crystalline materials, not much is known about their actual mode of formation and other details regarding their growth. An interesting and convenient method of studying the evolution of crystals is to follow the changes in the interference colours of thin crystals. Preliminary observations have been made on these lines by Perrin, Marcelin and others, who found among other things, that the increase in thickness is a discontinuous process, the smallest step being of molecular dimensions. L. Kowarski has taken up a further detailed examination of this interesting subject, and the first qualitative studies on the formation and growth of *p*-toluidine crystals by controlled sublimation, are reported in *J. de Chimie Physique*, 1935, **32**, 303. According to the state of the support, a razor blade, the sublimed crystals may be single, of uniform thickness, and possessing freely curved contours (curved region); or else, they may be in groups and aggregates in each of which there is a fixed orientation and stratification (oriented region). In this region, the appearance of the crystals is very complex, and the growth is particularly active in regions of recent formation (buds). On rapid heating small drops of liquid appear on the crystal surfaces. A number of phenomena indicate a reciprocal relationship between the movement of these drops and the intensity of crystal growth.

Metallic Membranes.

FOR the study of permeability and membrane equilibria, collodion membranes possess many valuable properties, but have the characteristic of taking up only a negative charge in aqueous solutions. It is however frequently desired to have a positive charge on the membrane, and this is achieved by such devices as loading the membrane with different dyestuffs. In this process not only the sense of the potential but also the whole complex of surface forces are altered. The corresponding method of charging amphoteric membranes (*e.g.*, gelatin) by changing the pH of the solutions has also similar complications. To get over this difficulty and to get a membrane whose change can be easily changed, N. V. Kultascheff and F. A. Santalow (*Z. anorg. allgem. Chemie*, 1935, **223**, 177) have studied the preparation and properties of metallic membranes. These membranes are successfully prepared by heating a thin foil of an alloy of two metals (*e.g.*, brass) so that the more volatile component evaporates leaving behind a membrane with pores of nearly molecular dimensions.

Atomic Weight of Protactinium.

THE atomic weight of not a single member of the Actinium series has so far been determined by purely chemical methods. Aston's work on Actinium D has no doubt given the value for the atomic weight of Protactinium as 231. In spite of the difficulties in getting appreciable quantities of Protactinium, A. V. Grosse (*Proc. Roy. Soc.*, 1935, **150**, 363) has prepared the double fluoride K_2PaF_7 in the highest state of purity, and after careful conversion to Pa_2O_5 found the ratio $K_2PaF_7 : Pa_2O_5$. He gives the mean value for the atomic weight of Pa as 230·6 with an accuracy of ±0·5. This precision determination of atomic weight is of importance in fixing up the atomic weights of the other members of the actinium series.

M. P. V.

Surface Tension of Aqueous Solutions of Electrolytes.

G. JONES AND W. A. RAY (*J. Am. Chem. Soc.*, 1935, **57**, 957) find that the surface tension of a sufficiently dilute solution of an electrolyte is *lower* than that of water itself. This observation is of great interest, if it is confirmed and shown to be a general phenomenon; and is of particular importance as it is not in accordance with the theories developed by Wagner and later by Onsager and Samaras.

K. S. G. D.

On the C—C Bond Energy.

W. LASAREFF has recently made a calculation of the C—C bond energy in diamond and aliphatic molecules (*Physica*, 1935, **2**, 737) which widely departs from the accepted values. He has argued that a carbon atom is in the (^5S) state while a carbon atom in the gaseous state is in the (^3P) state ($\Delta E = 97 \pm 5$ k. cals.) and that the difference between the energies of these two states has to be considered when calculating the C—C bond energy by means of the data regarding the sublimation heat. Lasareff's value for the bond energy in diamond is 132±3·5 k. cals., while the accepted value is about 75 k. cals.

Lasareff has also calculated the bond energy in the aliphatics which comes to 128 k. cals. It is clear that this calculation of the C—C bond energy will lead to important consequences for many problems in chemical calculations.

N. S. N.

Vitamin K.

THE nature and distribution of a vitamin, possessing curative properties against a deficiency disease resembling scurvy in chicks, but which cannot be prevented by ascorbic acid, has been described by Henrik Dam (*Biochem. J.*, 1935, **29**, 1273). The factor is designated Vitamin K, and constitutes the anti-hæmorrhagic factor (or factors) in the diet. It is fat soluble, being found in the easily soluble non-sterol fraction of the unsaponifiable matter. It occurs in hog liver, hemp seed, and in certain vegetables like tomatoes, kale and orange peel. It is different from Vitamins A, D and E; cod-liver oil is practically devoid of it. There is an enormous retardation of the clotting of the blood of chicks suffering from this hæmorrhagic diathesis, and the quantitative estimation of the Vitamin is based on the determination of the clotting time.

Asexual and Sexual Reproduction in Ascidians.

N. J. BERRILL (*Journ. Morph.*, 1935, **57**, No. 2), as a result of the comparative study of a number of ascidians, has come to the conclusion that the processes of bud development and sexual development are, in the ascidians, at variance. Initial bud masses may consist of cells varying from 40 (Distaplia) to 1,000 or more (Ectinascidia) and in all cases the cells undergo a number of cleavages before differentiation begins. Gross differentiation into parts of the organism occurs first and only later cytological or cellular differentiation is seen. In sexual development cleavage and differentiation are fundamentally dissociable, the rate of cleavage and the number of cells produced dependent on the yolk-cytoplasm ratio and the size of the egg respectively. Often in early development the differentiation noticed, refers not to the differentiation of the adult structure but to the precocious differentiation of peculiar larval structures. In some cases a telescoping of the differentiation of the larval structures takes place, without, however, affecting the development of adult structures. The author concludes that the difference between asexual and sexual reproduction really consists in the presence of a larval organisation in the latter, whose differentiation is due to the liberation of substances in the egg during maturation. The rest of the egg unaffected by this substance and which must solely be responsible for the development of the adult organism is usually small and repeated division must precede the differentiation of adult characters.

Development of *Patella vulgata*.

THE embryology of *Patella* is, in spite of the earlier memoirs of Wilson and Patten, still incomplete and in a number of respects our knowledge of this subject is inaccurate, as shown by F. G. W. Smith in his latest paper [*Phil. Trans. Roy. Soc. Lond.*, 1935, **225**, No. (B) 520, 95–125]. The divergence of opinion between Wilson and Patten regarding the origin of endoderm and mesoderm cells is cleared by the present author who states that the whole of the macromere in the quadrant D gives rise to mesoderm while the macromeres of quadrants A, B and C alone give rise to the endoderm. The foot arises in the form of single median protuberance. The development of the radula is for the first time completely followed and it is seen that the radular formula undergoes two changes before it assumes the adult arrangement. The entire process of torsion is described as well as the changes during metamorphosis.

A Petrographic Use of Fluorescence.

TILL now the property of fluorescence has been used for the determination of individual minerals. But recently Alonzo Quinn (*American Mineralogist*, Vol. **20**, No. 6) has shown that such a study could be extended to identify the textural relationships in igneous rocks, if they are photographed in ultra-violet light under special conditions. In connection with his study of the nephelite syenite, he has reproduced several such photographs where the distinction between the minerals is very clear. The hornblende is black, sodalite white and felspar and nephelite grey, thus showing that sodalite was the fluorescent mineral. Though such an investigation involves the employment of different types of films, filters and other specialised appliances for different rocks, yet the method will have considerable value

in the determination of textural relationships of minerals—especially fluorescent—in rocks.

Differentiation in Hawaiian Lavas.

At the present time a good deal of work has been done on the crystallisation of basaltic magma. For most of the American petrographers Hawaiian lavas have become the common material for petrographic work, and Barth's work on the rocks of the Hawaiian Islands has become classic, and his conclusions are in keeping with the experimental deductions of Bowen. But recently Howard A. Powers (*American Journal of Science*, V Series, No. 175) with an intimate knowledge of the Hawaiian volcanoes and lavas, has drawn attention to certain features which vitally affect the theories of magmatic differentiation. He has been able to trace a definite relation between magmatic differentiation and cycles of volcanic activity, and opines that "basalt of uniform composition represents essentially undifferentiated primary magma and the occasional eruptions of the decadent stage bring to the surface the various products that result from the differentiation of the original magma". With regard to the crystallisation of the pyroxenes in basalts he differs from Barth and holds that diopside phenocrysts do not form in primary magma and that orthorhombic pyroxenes should not be omitted from the sequence of pyroxenes in basalts.

Discussing the problems of magmatic differentiation so far as it applies to Hawaiian lavas, he has shown that different phases of volcanic activity produce different types of basalts from the most undifferentiated lime-basalts to the most highly differentiated nephelite-melilite basalt. In conclusion he suggests that "fractional crystallisation alone is not sufficient to explain the differentiation of the Hawaiian lavas".

Science Notes.

Growth of the Shoot in Asparagus racemosus *Willd.*—Mr. S. Sarup writes:—The elongation of the shoot of *Asparagus racemosus* Willd. is very rapid in the beginning, attaining a definite length before the axillary shoots begin to grow. Four shoots in a single young plant reached 80·5 cms., 76·7 cms., 75·9 cms. and 83·0 cms., in about a week's time. This height varies with the age, and the size and number of rhizomes. It was 300 cms. and 150 cms. in two other plants of different ages. In a young plant of *Asparagus sprengerii* the three shoots reached 29.1 cms., 32.0 cms., and 27.2 cms., respectively.

Growth of the shoot of Asparagus racemosus: *increase in cms. after every 12 hours.*

1st shoot								4.7	6.0	3.3	6.3	6.5	6.7	7.6	6.5	5.2	5.9	1.6	
2nd shoot					4.9	3.8	4.8	6.7	6.0	7.7	6.6	8.4	8.7	7.3	7.9				
3rd shoot	1.0	2.0	2.0	3.0	4.0	5.8	4.4	5.8	4.1	5.9	4.2	7.8	7.5	2.5	6.9	6.0	5.5	1.5	1.6
		Slow					Rapid				Max.					Slow			

The growth rate is slow in the beginning, then it becomes rapid until it attains a maximum when it gradually falls off. Taking the actual figures in one case (3rd shoot) we find that the rate of growth rises slowly in the early stages, then it becomes more rapid till it goes up to 7.8 cms. and 7.5 cms. every 12 hours and then it falls to 6.9 cms. for 12 hours. Then it begins to decrease a little till it falls from 5.5 cms. to 1.5 cms. The figures for the other shoots follow the same course.

The readings in the last column were begun as soon as the shoot tip had just come out of the earth and the observations were continued till the axillary shoots were developed. Some discrepancies are due to the fact that external conditions were not uniform.

There appears to be a periodicity in the day and night rates of growth. The suggestive figures for the 2nd and 3rd shoot are like this:—

2nd shoot	..	4.8	6.7	6.0	7.7	6.6	8.4		
3rd shoot	..	4.0	5.8	4.4	5.8	4.1	5.9	4.2	7.8
Shoot of *Asparagus sprengerii*	..	1.2	4.2	1.7	3.2	1.8	1.6	1.2	

In *Asparagus racemosus*, the rate of growth is about 25 per cent. higher in the day than in the night. During the day the plant is adding new material continually (*cf.* Blackman, V. H., *Annals of Bot.*, **33**, 353).

* * *

The Quaternary System CaO-Al_2O_3-SiO_2-Fe_2O_3 in Relation to Cement Technology Building Research Technical Paper No. 16. His Majesty's Stationery Office (Post Free 1s. 1*d.*).—The

demand for Portland cements possessing special properties has caused much attention to be devoted to the constitution of Portland cement and to the content of the various compounds present in it. The present report represents an application to cement technology of the results of a study of a portion of the quaternary system $CaO-Al_2O_3-SiO_2-Fe_2O_3$. The data available from that work permit of a closer definition of the conditions obtaining during the clinkering of a cement raw mix, and of the compound content of the clinker, than has previously been possible.

* * *

Report of the Chemistry Research Board for the Period ended 31st December, 1934—His Majesty's Stationery Office (Price 1s. 8d. Post Free).—The report gives a general review of the activities of the Chemistry Research Board's work started in the Chemical Research Laboratory in 1925. The Director of Chemical Research describes in broad outline the current researches, many of which are conducted with the aid of financial contributions from firms and institutions. In view of the nature of the researches, both academic and industrial, chemists will be interested in this first report which in one volume summarises the results previously published in numerous scattered papers.

* * *

The Relation between Illumination and Industrial Efficiency I. The Effect of Size of Work.—His Majesty's Stationery Office (Price 4*d.* Post Free 5*d.*).—This paper describes the first stage of an investigation the object of which is to find out whether the amount of light required for the efficient performance of the various tasks that have to be carried out in industry can be approximately calculated by examining the separate factors which together make up each visual task. The chief of these factors are size of object, contrast, rate of movement, and possibly colour; and the present paper gives the results of investigation to discover the effect of variations of size upon the illumination required. Further papers upon the relationship of contrast, and rate of movement, with illumination will follow.

* * *

Effect of Storage prior to Ginning on the Spinning Quality of Cotton.—Storage of seed-cotton for any length of time prior to ginning often brings about considerable modifications in the quality of the seed and the lint. The seed is apt to lose in germinating power and the lint to be attacked by bacteria and fungi which are associated to a greater or lesser extent with cotton. There is, however, a school of thought which holds the view that the quality of cotton, stored in seed, improves as a result of a sort of conditioning process during which the development of the fibre continues and some of the oil from the seed flows into it making it soft and pliable and thereby improving its spinning quality. This subject is fully discussed in the latest bulletin of the Indian Central Cotton Committee entitled *Effect of Storage prior to Ginning on the Spinning Quality of Cotton*, by Dr. Nazir Ahmad, M.Sc., Ph.D., F.Inst.P., Director, Technological Laboratory, Indian Central Cotton Committee. The author points out that in spite of the practice of storing cotton in seed, no experiments have so far been reported to test the validity of the above-mentioned views. He then gives an account of the experiments undertaken by him at the Laboratory which show that the storage of cotton in seed before ginning has no effect whatever either upon its mean fibre-length or fibre-weight per inch, showing that there is no justification for the view that the development of the fibre continues during storage. The results of spinning tests and wax determination on three Punjab cottons, *viz.*, Punjab-American 289F, Punjab-American 4F and Mollisoni, revealed that in the case of two cottons storage of seed-cotton before ginning did not bring any improvement either in the wax content or in the spinning performance. In the case of one cotton only, namely P.A. 289F, a small improvement in wax content and spinning performance was observed, but it would be rash to regard it as an argument in favour of delaying the ginning operation and to ignore the harmful effects of storage upon the quality of seed and lint. Giving overwhelmingly strong reasons against the practice of storing the seed-cotton, the author is of opinion that, if by force of circumstances, it should become necessary to store the seed-cotton for a while before ginning, every precaution should be taken to ensure the dryness of the sample, the absence of large quantities of dirt or trash and the absence of a particularly warm or humid atmosphere in the store room. If the period of storage should exceed a few weeks the seed-cotton should be occasionally taken out and exposed to sun. The booklet, which is available at the nominal cost of annas eight, has the rare feature of being useful to all interested in cotton industry, and for the production of which the author should be congratulated.

* * *

Indian Central Cotton Committee.—The 31st meeting of the Indian Central Cotton Committee was held on the 19th and 20th August, 1935, at the headquarters of the Committee, Vulcan House, Nicol Road, Ballard Estate, Bombay, under the presidency of Dewan Bahadur Sir T. Vijayaraghavacharya, K.B.E., Vice-Chairman of the Imperial Council of Agricultural Research, His Excellency the Governor of Bombay addressed the meeting.

Numerous questions of vital importance to the cotton industry in India were discussed. The agenda of the meeting included items on the formation of a compact block of long staple cotton in Sind and Government of Bombay's resolutions thereon; licensing of gins and presses; standardisation of weights for cotton transactions; proposed additions and amendments to the bye-laws of the East India Cotton Association Ltd., relating to cotton options and the scheme for the publication of cotton forecasts. Broadcasting in the mornings of commercial news on cotton; railway freight rates on cotton and the mixing of Punjab-American cotton were also discussed.

In addition to the above, as is usual at the monsoon meetings the Committee reviewed the progress made on its various research and seed schemes.

Among the new schemes proposed to be introduced are (1) scheme for introduction and extension of B.D. 8 cotton in Broach district, (2) scheme for extension of cultivation of long staple cotton in Bengal, and (3) revised seed schemes for the distribution and extension of Jaywant and Gadag

No. 1 cottons in the Southern division of the Bombay Presidency.

* * *

Biochemical Society, Calcutta.—At the Annual General Meeting of the Biochemical Society, Calcutta, held at the All-India Institute of Hygiene on July 11, the annual report of the Secretary and Treasurer was presented by the Secretary, Dr. B. C. Guha. In course of the report, the Secretary said "The Biochemical Society, Calcutta, was inaugurated in a meeting held at the All-India Institute of Hygiene on July 6, 1934. The need of such a Society for the promotion of biochemical studies and research had been felt for some time and it was hoped that the creation of such a scientific body in Calcutta would evoke local response. In this expectation the promoters of the Society have been fully justified. The record of last year's work shows good progress and stimulates hope for the future."

Since the inauguration of the Society in July, 1934, ten meetings have been held in which the following fourteen papers have been read and discussed. The papers display a wide range of interests.

(1) B. Ahmad—The Metabolism of Carotene. (2) A. C. Roy—Cultivation of micro-organisms on vegetable media. (3) S. C. Banerjee and H. K. Sen—Catalytic activation of diastase. (4) R. C. Bhattacharjee—The therapeutic applications of snake venom. (5) A. R. Ghosh and B. C. Guha—Vitamin C in Indian foodstuffs. (6) B. Ahmad—The excretion of Vitamin C in human urine. (7) P. C. Mitter and N. N. Chatterjee—The formation of purines from iminazoles. (8) B. N. Ghosh—The combination of antigens with anti-bodies. (9) N. R. Chatterjee, D. N. Chatterjee, Pasricha and S. Ghosh—Effect of bacteriophage on the enzyme activity of vibrio choleræ. (10) A. C. Roy—Biochemistry of snake venom. (11) J S. Chowhan—Therapeutic uses of snake venom. (12) B. C. Guha and H. G. Biswas—Flavines and Vitamin B_2. (13) B. C. Guha and A. R. Ghosh—The biological synthesis of ascorbic acid. (14) H. E. C. Wilson and S. L. Mukherjee—Some observations on the composition of the urine in relation to calculus formation.

At the annual meeting, the following papers were read:

(1) N. Das and B. C. Guha—The respiration of *Bact. Staphylococcus*.

(2) A. R. Ghosh and B. C. Guha—The relation between dietary composition and the urinary excretion of ascorbic acid.

For the next year the following have been elected to form the Committee:

Mr. N. M. Basu, Dr. P. K. Bose, Dr. P. De, Dr. J. N. Mukherjee, Dr. S. N. Ray, Mr. A. C. Roy, Dr. B. B. Sen and Dr. H. E. C. Wilson. Dr. S. Ghosh and Dr. B. C. Guha have been elected Honorary Secretaries and Dr. B. Ahmad, Honorary Treasurer.

* * *

Association of Economic Biologists, Coimbatore.—A meeting of the Association was held on the 26th June 1935. Two interesting papers were read:—(1) Intercultivation in dry cottons by V. Ramanatha Ayyar; (2) Effect of certain cultural practices on the cocoanut by J. S. Patel and K. W. Chakrapani Marar. On 22nd July 1935, Mr. W. B. Gurney, Entomologist, New South Wales, Australia, delivered an interesting lecture on "Some aspects of Economic Entomology in Australia". On 29th July 1935, Dr. E. K. Janaki Ammal read an illuminating paper on "Cytogenetic studies in *saccharum Spontaneum* L."

* * *

Academy of Sciences, U.P.—The ordinary monthly meeting of the Academy was held on Saturday, April 20, 1935, at 9-30 a.m. in the Physics Lecture Theatre under the presidency of Prof. N. R. Dhar and was attended by a large number of members. The following were elected new members of the Academy:—Drs. Rangadhama Rao and Ramkrishna Rao of the Andhra University; Profs. N. R. Sen and P. C. Mahalanobis of the Calcutta University; Dr. D. N. Wadia, Geological Survey of India; Prof. Ajrekar of the Guzarat College; Dr. Rangaswami Ayyangar of the Rice Research Institute, Coimbatore; Dr. Normand, Director-General of Meteorology; Rao Bahadur B. Viswanath, Imperial Agricultural Chemist, Pusa; Prof. Mowdawalla, Principal of the Government Engineering College, Bangalore; Lt.-Col. R. N. Chopra, Principal, School of Tropical Medicine, Calcutta; Mr. Champion, Silviculturist, Dehra Dun; and Mr. Pinfold of the Attock Oil Company.

The President made a short speech reviewing the progress of the Academy. He said that in view of the increasing number of papers received by the Academy, the Bulletin has been converted to Proceedings. It is gratifying to find that the publication has been much improved, and it is now quite regular. The position of the Academy has been recognised by foreign learned bodies like the Academy of Sciences, France, the Prussian Academy of Sciences, the National Academy of Sciences of America, the Royal Society of Edinburgh, the Imperial Academy of Sciences, Japan and about a hundred other bodies which are regularly exchanging their publications with ours. The Council has recommended that a temporary officer be appointed next year to deal with the publication and quick despatch of business. The Academy has been recognised to be an all-India body by the Indian Science Congress, and it is gratifying to find that a large number of Scientists of repute from other parts of India have agreed to join the Academy.

In view of the changed circumstances, the President remarked that the Council of the Academy has decided to widen its scope of activities, and has redrafted the existing rules and regulations. It has been decided to increase the number of Fellowships to one hundred and change the name to "National Academy of Sciences, India". These proposals are now being circulated amongst the members, in accordance with company rules, and after the usual ceremony, will be placed before the Academy for final sanction.

The Government of the United Provinces has very kindly sanctioned a recurring grant of Rs. 2,000 per year, and appeals have been made to other Governments and learned bodies for financial grants to enable it to cope with its increased activity. The President hopes that in view of the increasing usefulness of the Academy to the country, these appeals will meet with response. The Academy is already finding its accommodation cramped and an appeal for a building fund will shortly be issued.

About a dozen papers were read before the Academy. The President read a paper in which

he showed that the addition of molasses to the soil considerably aids the fixation of nitrogen and this is ascribed partly to the action of light in the tropics. Dr. S. Dutt described the isolation, analysis and the synthesis of the active principle of an Indian Medicinal plant *Glycosmis pentaphylla* which is highly recommended by the Indian physicians for a number of diseases. Mr. Satyendra Ray's paper on a modified theory of gravitation base on Sulaiman's theory provoked very active discussion and his assumptions and method of work were criticised by Dr. Kothari from Delhi and Dr. Mazumdar from Lahore. Messrs. Agarwal and Dutt described the results of their analysis of the bark of *Terminalia arjuna*, a plant of great medicinal use. Messrs. Toshniwal and Pant described the results of their recent measurements of the height of the ionosphere and its electron content. Mr. Bajpai described certain anomalous results which he obtained on the measurement of the height of ionosphere during the total lunar eclipse. Mr. S. P. Jain read a paper on Taylor's Series and Borel's Polygon of Summability.

Mr. Har Dayal Srivastava described a new parasite referable to a new genus of the Subfamily *Dinurinæ*. It is a very rare parasite in the stomach of ilisha fish. In another paper Mr. Srivastava gave an account of a new member of the family *Monorchidæ* from sauri fish. Mr. B. P. Pande read his contributions to the Digenetic trematodes from the microchiroptna of Northern India. Mr. S. C. Varma described new species of *Bucephalopsis* and *Bucephalus* and provisionally created a new genus *Trilentacularia*.

* * *

Report of the Extraordinary Monthly Meeting of the Academy of Sciences of the United Provinces of Agra and Oudh held on Friday, May 10, 1935, at 6 P.M.:—Prof. A. C. Banerji, Vice-President of the Academy, was in the Chair. The following papers were read and discussed:—(1) MESSRS. R. N. GHOSH AND L. P. VARMA, Physics Dept., Allahabad University, Allahabad: *On the Application of Heaviside's method to the Problem of Vibrations of Pianoforte String.* (2) MR. HAR DAYAL SRIVASTAVA, M.Sc.: *New Amphistomatous Parasites from an Indian Freshwater Fish.* (3) MR. HRISHIKESHA TRIVEDI, M.Sc.: *The Absorption Spectra of the Vapours of Oxides of Copper, Iron, Nickel and Cobalt and the Determination of their Heats of Sublimation.* (4) MR. HRISHIKESHA TRIVEDI, M.Sc.: *The Absorption Spectra of the Vapours of the Mono-Sulphides of Iron, Nickel, Cobalt, Copper and Tin, and the Determination of their Heats of Sublimation.*

* * *

Scripta Mathematica: April 1935 (Vol. III, No. 2) R. C. Archibald. "*Mersenne's Numbers.*"—An authoritative paper giving "accurate and complete information concerning present knowledge" of what are known as Mersenne's Numbers —the 55 numbers 2^p-1 where p is one of the primes 2, 3, ..., 257. Indian Scientists will note with an element of delight that V. Ramesam has been quoted as the first to give two of the factors of $2^{71}-1$, *viz.*, 48544121 and 212885833. (*Journ. Indian Math. Soc.*, 1912, 4, 56.)

The same author in a paper which is concluded in this issue gives an up-to-date account of the results which have been obtained in the attempts to prove the famous Goldbach's Theorem.

* * *

The Perpeti Meteorite.—One of the interesting exhibits shown and commented upon by Dr. A.L. Coulson, at the ordinary meeting of the Asiatic Society of Bengal held on Monday, the 5th August 1935, was the Perpeti Meteorite. "At 11 P.M. on the 14th May 1935, a meteoric shower occurred in the vicinity of the villages of Perpeti (23° 19′ 30″ : 91° 0′ 0″), Bhateswar, and Pilgiri under the jurisdiction of the Chandina police station, and near other villages under the police stations of Kachua and Hajiganj, in the Tipperah district of Bengal.

"Eleven pieces in all were recovered. The total weight of all specimens is 21,942·57 grams; the largest one weighs 6,689·85 grams. The specific gravity of the meteorite is 3·554. It is being analysed by Mr. P. C. Roy.

"The meteorite, which has been registered as No. 298, Stone, in the collections of the Geological Survey of India, has been classified provisionally as No. 14, White Chondrite (Cw.) in Brezina's terminology. It has a white, rather friable mass with few, chiefly white, chondri."

* * *

Gift of the International Union of Chemistry.—The last Conference of the Union held in April 1934 in Madrid, eager to help the Committee of the A.T.C. to go on with the work, had agreed to transfer to the Committee an important part of the Funds of which the Union disposes.

This decision was voted unanimously by the Union's Executive in Paris, October last and confirmed by National Organisations representing the various countries at the Union (*e.g.*, Verband Deutscher Chemischer Vereine representing Germany, Comité National Belge de Chimie representing Belgium, National Research Council, Division of Chemistry representing the United States, etc.).

The sum thus put at the disposal of the Committee of the A.T.C. is 150,000 francs. The large amount shows the interest which the international chemical circles attach to the continuation of the A.T.C. This sum will be used up for the printing of the Index of the second series (Vols. VI to X—1923-30), now ready at the Editorial Office.

In compensation of this gift the Committee of the A.T.C. is going to put at the disposal of the chemical organisations adhering to the Union a certain number of complete sets. This number and the mode of their distribution are to be established shortly. (*Communicated by Dr. Ch. Marie, General Secretary of the A.T.C.*)

* * *

A three-year entomological scheme to combat a serious cotton pest due to a black-headed cricket, has been approved by the Sind Cotton Committee, at a recent meeting. The Scheme will be submitted to the Sind Central Cotton Committee for grant of financial aid.

* * *

The Institute of Brewing.—The Collective Index of the *Journal of the Institute of Brewing* for the years 1924–34, inclusive, will shortly be published. The price will be 12*s.* 6*d.* to Members and 25*s.* to non-Members, postage free. Those who are desirous of securing a copy of this publication

may communicate with *The Secretary, Institute of Brewing, Brewers' Hall, Addle Street, London, E. C.* 2.

* * *

New Broadcasting Station at Delhi.—The main details of the new broadcasting station at Delhi, which is to be erected and worked by the Indian State Broadcasting Service are now settled. The transmitting station will be located to the north of Old Delhi on the Ambala Road near the intersection of Probyn Road and the Mall and the construction of the station building will be begun shortly. The frequency response is substantially uniform from 30 to 10,000 cycles per second, which will give reproduction of a very high standard. The wavelength chosen for initial working is approximately 340 metres, the precise frequency being 882 kilocycles per second. In order to obviate any possible interference to be caused to reception of Indian stations in India by high power broadcasting stations in Europe and other parts of the world, particularly at night and at the extreme range of the Indian stations, a continuously variable valve-type of frequency control has been selected in preference to a crystal, which would not permit of any rapid change of wavelength. The frequency stability of the apparatus chosen is adequate for Indian conditions.

As regards power, the station is rated at 20 kilowatts to the aerial with distortionless modulation of 90 per cent. and the station will thus have an effective power more than ten times that of the present stations of the Indian State Broadcasting Service at Bombay and Calcutta. The aerial system will be of the quarter-wave type and will be supported by two masts 100 metres high, *i.e.*, approximately 330 ft. The masts which are of the stayed lattice type, will be insulated from the ground and their electrical properties can be adjusted in order to increase the radiation in certain directions. This will permit the energy to be directed towards the more densely populated areas which lie roughly to the north-west and south-east from Delhi. The mast alignment has been adjusted to this direction.

It is generally agreed, that in the absence of exceptionally severe atmospherics and interference from electrical apparatus, a field-strength of one millivolt per metre should give reliable reception with comparatively simple receivers. It is estimated that the Delhi station will give this field-strength upto a distance of 85 miles in all directions during the day. Modern receivers will, however, give good results when conditions are reasonably favourable with a field-strength of one-tenth millivolt per metre and the Delhi station is estimated to give this field-strength upto a distance of 240 miles. It is fairly certain that during the cold weather and at other times when conditions are favourable, Lucknow and Cawnpore to the south-east and Lahore to the north-west will be able to receive the Delhi station even during the day time. It is anticipated, however, that on the average, field-strength at night will be about one-third millivolt per metre upto 600 or 700 miles, which will bring within range of Delhi practically the whole of Northern India, including most of the hill stations in the Himalayas.

Apparatus has also been ordered for the fitting of the studios in accordance with the best modern practice, but the precise location for the studio has not yet been decided.

As regards programmes, a service of about 4 hours daily will be provided at first, though this will probably be increased as support is obtained in the form of licences in the neighbourhood. A very substantial portion of the programme will be in Indian languages and based on the indigenous culture of the surrounding area. The proportion of European programmes will depend on evidence of the public taste obtained in practical working. The British Broadcasting Corporation have kindly granted permission to the Indian State Broadcasting Service to relay the programmes of the Empire Broadcasting Service and arrangements will be made to construct a special receiving station near Delhi for this purpose. European programmes of a high quality will thus be available. Arrangements will also be made for items specially directed towards the general uplift of rural districts in the immediate neighbourhood.

It is not possible at this stage to give a definite date by which the station will be working, but it is hoped that experimental programmes will be given in November and that regular programmes will be broadcast well before the end of the next cold weather.—(*Extracted from the Indian Radio Times*, 22nd May 1935.)

* * *

Colloidal Copper for Leprosy.—Dr. William Noble of the Salvation Army in Travancore, as a result of his work in collaboration with Dr. Denny of the Leper Colony, Louisiana, will soon start a new treatment which has already given very good results in the hands of Dr. Denny, for Leprosy. The disease is due to a microbe which occurs only in persons who are pre-disposed due to mal-nutrition and weakness, and is generally caused through other illnesses. By building up resistance and concentrating solely on proper feeding and curing of other diseases, the leprosy microbes not only decreased in intensity but also ultimately disappeared. The treatment is slow compared with the unpleasant chaulmoogra. More recently colloidal copper has been found to be a good substitute for the chaulmoogra. The treatment is rapid and effective and very good results have already been obtained by Dr. Denny by copper injections.

* * *

Ootacamund Observatory.—At the instance of the Ootacamund Municipality, the India Meteorological Department has restarted the observatory at Ootacamund which was in existence from 1901 to 1923. The usual instruments of a III class observatory, *viz.*, a barometer, a Stevenson screen, a set of four thermometers, an anemometer, a wind vane and a rain-gauge, have been loaned by the India Meteorological Department and have been installed at suitable sites under the personal supervision of an officer of the department who was deputed to the station for the purpose in the 1st week of July.

The observatory will be maintained by the Municipality and will be under the technical supervision of the India Meteorological Office. For the present, a copy of the daily meteorological data will be posted by the Municipality to the India Meterorological Office in monthly registers,

Professor A. C. Seward, Professor of Botany, Cambridge University, has been invited by the Indian Universities to deliver a series of lectures at the various educational centres in India.

* * *

We learn with great pleasure that Dr. B. K. Das, Professor of Zoology, Osmania University, Hyderabad (Deccan), having received a special invitation from the International Zoological Congress to be held at Lisbon, is being deputed to attend the same. He will read a paper on "Certain characteristic features of the Hyderabad fauna". Besides, he will also deal with certain important aspects of the Osmania University for which he has been requested by the Congress. He is sailing on the 20th of this month and will be back about the 1st week of November next.

* * *

It is understood that Professor J. N. Mukherjee, of the University of Calcutta, will be deputed by the Imperial Council of Agricultural Research to represent India at the International Soil Science Conference, London.

* * *

Sir Hari Singh Gour and Dr. M. A. Moghe of the Nagpur University will represent the University at the next Quinquennial Congress of Universities of the Empire to be held at Cambridge in 1936.

* * *

The Hon'ble Mr. A. G. Clow, C.I.E., I.C.S., Joint-Secretary, Department of Industries and Labour, Government of India, has been appointed as the first Chairman of the newly created Council of Industrial Intelligence and Research Bureau of the Government of India.

* * *

The Andhra Scientific Co., Ltd., Masulipatam.—We have recently received from Messrs. The Andhra Scientific Co., Masulipatam (S. India), a "check valve" and a reprint of a paper on the device published in the *Journal of the Indian Chemical Society* (1934, 11, 659). The valve constitutes a very simple device for effectively preventing back suction which is a common experience, due to slight diminution in the rate of evacuation, in the laboratory. In actual use, the valve comes next to the pump so that when the pump is disconnected, the reduced pressure in the evacuated space is maintained. This has now been placed on the market and thus made widely accessible.

We also understand that the Company have specialised in the manufacture of special regulator resistance for high output suitable for 120 and 220 volt mains, weight boxes, balances and drying ovens, of standard quality. They are also prepared to undertake manufacture of any new laboratory device from scientific workers.

* * *

We are glad to felicitate Dr. Muhammad Abdul Hameed Siddiqui, Professor of Anatomy, King George's Medical College, Lucknow, on his being awarded the Vincent Massey Scholarship.

Professor Siddiqui took the B.Sc. Degree in 1923, from the Canning College, Lucknow University. He then joined the King George's Medical College, Lucknow, and passed the M.B., B.S. examination in 1928, with distinction in Pathology coming out First in the University. He was the recipient of a University Scholarship and many medals and certificates of honour. In 1930, he took the M.S. degree of the University, being the first candidate to get that degree from the University. He went to Europe for higher studies and in 1931, he obtained the D.L.O. & R.C.S. (Eng.) and in 1932, the F.R.C.S. degrees. In 1932, he was appointed Professor of Anatomy, King George's Medical College, Lucknow, which appointment he is holding to date. In 1933, he went to London for a short period to attend the meetings of Anatomical Society of Great Britain.

* * *

Announcement :—

Woodhouse Memorial Prize, 1935.—Mr. C. A. MacLean, Officiating Director of Agriculture, Bihar and Orissa, writes :—

"In memory of Mr. E. J. Woodhouse, late Economic Botanist and Principal of Sabour Agricultural College who was killed in action in France in 1917, a biennial prize in the form of a silver medal and books of a combined value of Rs. 100 will be awarded to the writer of the best essay on a subject of botanical interest to be selected from the list noted below. The length of the essay should not exceed 4,000 words.

1. Intergeneric hybrids and their importance to agriculture.
2. The problem of rust of wheat in India.
3. The constancy of agricultural and botanical characters of paddy and their suitability for being used in a scheme of classification.
4. Rotation of crops in relation to the eradication of weeds.

The competition is open to graduates of Indian Universities and to Diploma holders and Licentiates of recognised Agricultural Colleges in India, who are not more than 30 years of age on the date of submission of their essays.

Papers should be forwarded to the Director of Agriculture, Bihar and Orissa, Patna, before November 1st, 1935.

Failing Papers of sufficient merit, no award will be made. Essays must be typewritten on one side of paper only.

Academies and Societies.

Academy of Sciences (United Provinces of Agra and Oudh, India):

May 1935. L. P. VARMA: *On the Determination of Absorption Coefficient of Sound for Different Materials.*—Some Absorption Coefficients at 512 frequency for some commercial absorptive materials have been obtained by the Stationary Wave Method of E. T. Paris. The absorption coefficient of embossed metal plate coated with a blue paint (extensively used for ceilings of auditoriums) was found to be 0·25. BINAYENDRA NATH SEN: *On the Direct Formation of Bromides and the Distance of the Closest Approach of Atoms of Bromine.*—The distances of closest approach of atoms of metals determine their capacity to react with bromine. This value should be above 1·73 Å. BRAJ KISHORE MALAVIYA AND SIKHIBHUSHAN DUTT: *Photoreaction in Tropical Sunlight.*—2 per cent. solutions in appropriate solvents of aromatic amines, mono- and poly-hydric phenols, diamines, dyestuffs, aliphatic hydroxy acids, unsaturated acids, aminophenols and their derivatives, amino acids, aldehydes, hetero-cyclic compounds, aromatic oximes, phenylhydrazine and sulphocarbamide, were exposed to sunlight for periods varying from 42 to 156 days. The products obtained have been examined. N. R. DHAR AND S. K. MUKERJI: *Some Aspects of Nitrogen Fixation in Soil.*—The experimental results show that in absence of bacteria, the photo-oxidation of the energy rich compounds leads to the fixation of nitrogen in soils. MOHAMMAD HAMID KHAN: *On Eight New Species of the Genus* Cyclocœlum brandes *from North Indian Snipes.*—For the first time eight new species of the genus *Cyclocœlum* which are exclusively parasitic in the air sacs or the body cavities, have been described. B. P. PANDE: *Contributions to the Digenetic Trematodes of Microchiroptera of Northern India. I.*—Two new species of distomes belonging to the subfamily *Lecithodendriinæ* Looss and to the genus *Pycnoporus*, from the Indian insectivorous bats have been reported. HAR DAYAL SRIVASTAVA: *New Hemiurids (Trematoda) from Indian Freshwater Fishes. I.*—Two new species of *Lecithaster* have been reported from the common fresh water fish, *Clupea ilisha*. P. R. BHAGWAGAR: *Some Polyporaceæ from the Central Provinces.*—From a large collection of fungi made during the rainy season of 1930 from certain areas of Central Provinces, five species have been described. A. T. MOSHER: *Determining Sizes of Mangum Terrace Outlets.*—A formula has been derived for calculating the sizes for open channel terrace outlets for agricultural purposes.

Indian Academy of Sciences:

July 1935. SECTION A.—T. S. WHEELER: *On the Theory of Liquids. IV.*—Equations have been deduced for the forces on a particle vibrating in a spherical space under the influence of attractive and repulsive forces between that particle and uniformly distributed matter outside the spherical space. I. CHOWLA: *Some Problems of Waring's Type (III).* P. RAMA PISHAROTY: *Laminar Diffraction and the Becke Phenomenon.*—A sharp laminar edge appears as a dark line bordered by asymmetric fringes when examined in direct illumination under a microscope. This is explained as due to asymmetric diffraction effects at the edge. GURDAS RAM, V. I. VAIDHIANATHAN AND E. M. TAYLOR: *Potential Distribtuion in Infinite Conductors and Uplift Pressure on Dams.*—The distribution of pressure in the sub-soil under dams is the same as potential distribution in conductors. R. K. ASUNDI AND R. SAMUEL: *The Near Ultra-Violet Absorption Bands of SO_2.*—A number of new bands have been recorded and an analysis interpreting the bands as a uniform system is presented. A. VEERABHADRA RAO: *Raman Spectrum of Carbon Disulphide.*—The intensity distribution in 656 cm.$^{-1}$ is similar to that obtained in the wings accompanying the Rayleigh lines in liquids. R. Industrial Outlook.

The Industrial Manufacture of Absolute Alcohol—II.

By Jean Caupin.

IN a previous article[1] an account was given of the azeotropic process employed for the dehydration of aqueous alcohol. This process, as employed for the first time in France in 1923, consisted in sending alcohol of about 95 per cent. strength obtained by the ordinary process into a second independent apparatus, wherein, by employing benzene as entraining liquid, absolute alcohol of 99·8—99·9 per cent. strength was obtained.

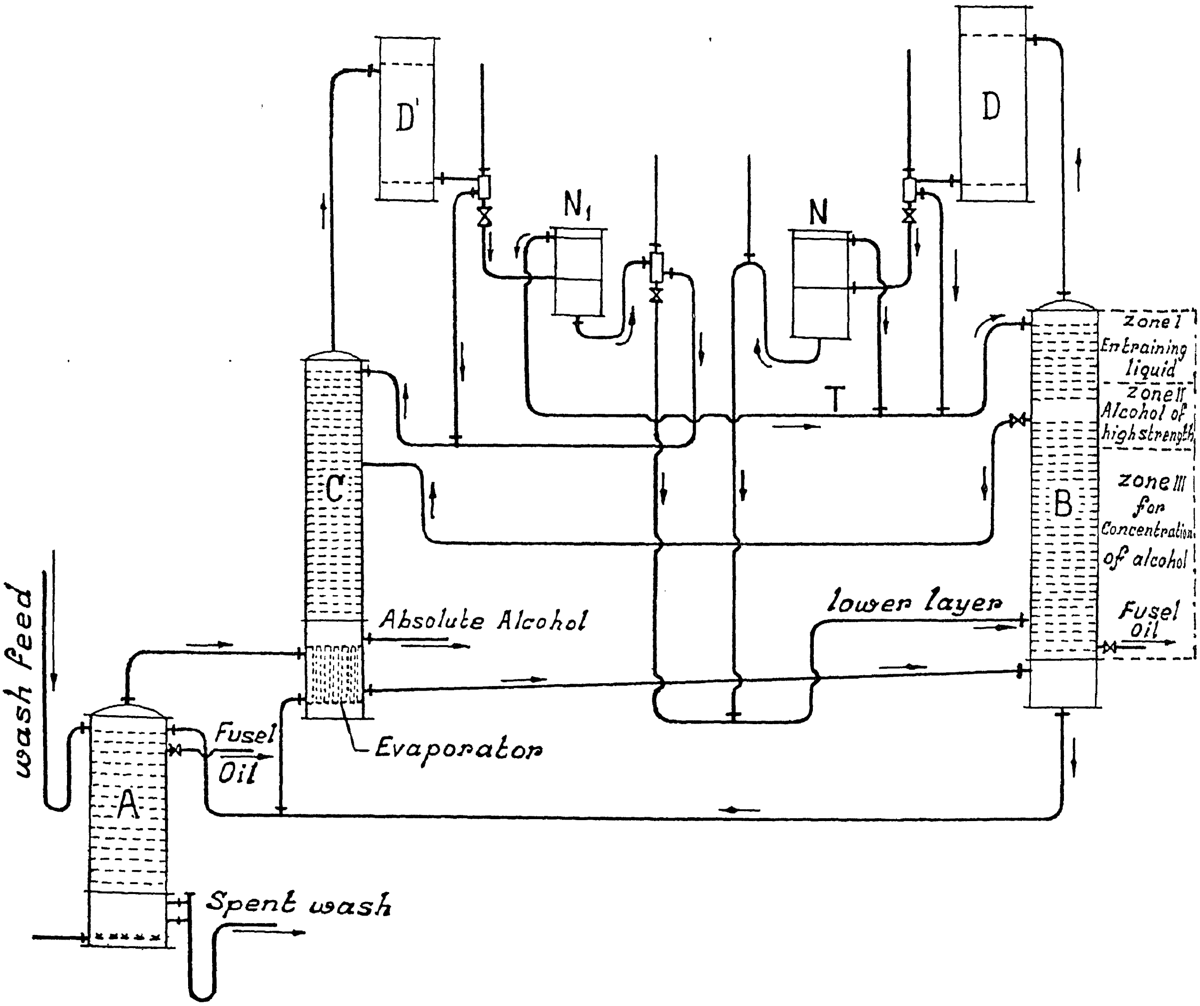
Recently, however, the researches of Guinot, the inventor, have rendered possible the manufacture of absolute alcohol from weak fermented liquors in a single operation instead of in two stages as was carried out in former years. At first sight, the above improvement appears to be impossible of attainment owing to the fact that, whereas in the ordinary process of rectification of alcohol, the concentrated alcohol is drawn off from the top of the column and water collects at the bottom, the reverse is true of the azeotropic process, *viz.*, the last traces of water present in the alcohol are carried to the top of the column and absolute alcohol collects at the base. This incompatibility is, nevertheless, easily resolved in practice, because the alcohol of high strength which collects in the upper plates of the concentrating column of the rectifier serves as an effective barrier owing to its ebullition point, which permits the addition of supplementary plates where the entraining liquid can work without difficulty for removing the last traces of water.

It will now be easy to examine and appreciate the scheme shown in the sketch of the equipment employed in industrial practice.

The fermented wash enters the column A and descends from plate to plate getting gradually exhausted at such a rate that the larger part of the water collects at the base. The alcoholic vapours heat up the column C and then undergo concentration in the column B. In the upper part of column B where the entraining liquid is introduced, the vapours present are similar in composition to that of the ternary mixture of water, alcohol and entraining liquid. The vapours are condensed in D and the liquid produced enters the decanter N where it separates into two layers. The upper layer which is a mixture of practically anhydrous alcohol and the entraining liquid returns continually to the top of the column.

Between the zone containing a high proportion of entraining liquid and the zone in which concentration of alcohol is effected,

[1] *Curr. Sci.*, 1935, 3, 385.



there is found a range of 4–5 plates containing alcohol of high strength (98·5–99 per cent.) mixed with a little of the entraining liquid. A suitable quantity of mixture is sent into the column C which is heated at the surface, and in which by continuous distillation it is possible to drive out completely the small quantities of water and entraining liquid present.

The absolute alcohol is drawn off at the base of column C, which is kept heated by the vapours arriving from column A. The quantity of heat furnished during the exhaustion of the weak alcoholic liquors is found to be sufficient to effect the concentration. The remarkable advantages of the method outlined above consists in (1) absolute alcohol can be manufactured in a single unit and at the same price as rectified alcohol, and (2) dehydration is easily effected with 4 per cent. of head products as against 10 to 15 per cent. in the ordinary rectification.

Further, the recuperation by an easy method of the vapours of the entraining liquid and alcohol permits keeping the loss of benzene below 0·04 per cent. This last improvement is of great importance for the development of the process, because the most important outlet for absolute alcohol is in its use as motor fuel with admixture of petrol.

It is essential, however, that in case of war and menace of blockade, the industry will not come to a standstill, if the special entraining liquids cannot be imported.

It is easy to demonstrate that with a minimum stock of benzene, a country like India can produce considerable quantities of absolute alcohol by the azeotropic method.

The total consumption of petrol in India

in 1931 was 72 million gallons. Admixture of 20 per cent. of alcohol with petrol will permit of the utilisation of about 14 million gallons of alcohol which could be produced from 7 million maunds or 250,000 tons of molasses.

This production of alcohol can be assured with 30 factories, each producing 2,000 gallons per day. The quantity of entraining liquid required for the starting of all these 30 factories will be roughly 6,000 gallons. The loss of entraining liquid will not exceed one gallon per working day for each distillery and the annual loss during the production of the total requirements of alcohol will only be 6,000 gallons of entraining liquid.

This quantity is not sufficient for the establishment even of a small factory for the production of the entraining liquid in India because a small stock will satisfy the requirements of many years. The above explanation will, therefore, eliminate the adverse criticisms regarding the azeotropic method.

We give below the cost of production of rectified alcohol, absolute alcohol by the First Technique (transformation of 96 per cent. into 99·8 per cent.), and absolute alcohol by the Fourth Technique obtained directly from fermented wash.

Approximate cost of production per gallon of (1) *Rectified Spirit,* (2) *Absolute alcohol by the First Technique, and* (3) *Absolute alcohol by the Fourth Technique.*[2]

Basis of Calculation :—

We will take for our basis of calculation the following, which are actually those that prevail in India:

Crushing capacity of the Sugar Factory: 400 to 600 tons.

Capacity of the Distillery: 750 maunds of molasses, *i.e.*, about 1,500 gallons (minimum) of alcohol every 24 hours, 200 working days, making an annual production of 300,000 gallons.

Price of molasses Re. 0–4–0 per Bengal maund.

Fuel: wood at Rs. 7 a ton.

1 lb. of wood gives 2 lbs. 8 oz. of steam, *i.e.*, price per lb. of steam is Re. 0–0–0·24.

We shall assume that the steam will be supplied by the boilers and the water by the pumps of the Sugar Factory.

(1) *Cost of obtaining a gallon of Rectified Spirit* :—

	Rs.	A.	P.
1. Building and Plant: about Rs. 187,500, to be redeemed in 10 years, *i.e.*, per gallon..	0	1	0
2. A maund of molasses ought to give two gallons of alcohol..	0	2	0
3. Consumption of steam; starting from fermented wash to obtain rectified alcohol: 38 lbs. at Re. 0–0–0.24 per lb., *i.e.*,..	0	0	9.12
4. Chemical products	0	0	0.73
5. Labour and staff: 9 men and 3 Indian chemists	0	0	3
6. Overhead expenses (Insurance, fire, interests, upkeep, office expenses)	0	0	4
Total expenses per gallon of rectified alcohol	0	4	4.85

The cost per gallon is about four annas six pies.

(2) *Cost of obtaining a gallon of Absolute Alcohol by the First Technique* :—

1. Cost of rectified alcohol ..	0	4	6
2. Consumption of steam, starting from rectified alcohol to obtain absolute alcohol: 13 lbs. of steam at Re. 0–0–0.24 per lb.	0	0	3.12
3. Loss of alcohol, *i.e.*, the difference between the quantity of alcohol that enters and that which comes out of the dehydration apparatus: 0.15 per cent. at Re. 0–4–6 a gallon	0	0	0.08
4. Loss of carrying liquid (Benzol): 0.01 per cent. at Rs. 3–7–0 per gallon	0	0	0.28
5. Plant: about Rs. 50,000 to be redeemed in ten years ..	0	0	3.20
6. Staff: 2 men	0	0	0.20
7. Royalties, about	0	0	5.50
Total price per gal.	0	5	6.38

The cost per gallon is about five annas six pies.

(3) *Cost of obtaining a gallon of Absolute Alcohol by the Fourth Technique* :—

Same consumption of steam as for rectified alcohol.

No loss of alcohol.

Same staff.

As a result of which the cost price is the same as that for rectified alcohol.

Four annas six pies.

Remarks :—

From the commercial point of view, the costs given above are perhaps excessive, because they are based on consumption of expensive fuel and also that all the molasses produced in a sugar factory can be sold at four annas per maund,

[2] The writer has, from actual experience in India, confirmed these figures.

In a succeeding article, it is proposed to discuss the very important question of alcohol as a fuel for power-raising purposes, and also to indicate the possibilities shown by the starting of the Distillery of the Mysore Sugar Factory, Mandya, the entire plant for which was furnished by *Ateliers Pingris et Mollet-Fontaine Reunis, Lille, France.*

Reviews.

HAND- UND JAHRBUCH DER CHEMISCHEN PHYSIK. Edited by A. Eucken and K. L. Wolf. Volume 9, Part 2. (Molekul- und Kristallgitterspektren. Akademische Verlagsgesselschaft M.B.H., Leipzig, 1934.)

This volume contains authoritative articles by Reinkober, Teller, Mecke and Finklenburg on the experimental methods of infrared spectroscopy, the theory of molecular and lattice spectra in the long wave region, the band spectra of diatomic molecules and finally the structure of some special molecules based on their spectra. In the article on the infra-red spectroscopy, Reinkober has given an account of the various sources of radiation, the different instruments for receiving the radiation, the experimental methods of the analysis of the radiation and the determination of wave-lengths in it. This account of the experimental methods seems to be fairly comprehensive. The theory of molecular spectra in the long wave region has been dealt with by Teller in a very clear fashion. He has presented the theory of the vibration, the rotation and their interaction in the case of a diatomic molecule both on the classical and quantum-mechanical standpoints and also their activity in the infra-red and Raman spectra. Next, the normal vibrations of a polyatomic molecule, their symmetry properties and the selection rules governing their activity in the infra-red and Raman spectra have been dealt with. The rotation of a polyatomic molecule, the interaction of rotation and vibration and the isotope effect in vibration have been also treated. In the next article on the lattice spectra, he deals with the total reflection in the vicinity of a region of absorption and the vibrations of a linear lattice. He has pointed out the relations that exist between the spectra and other properties of crystals. The article on band spectra by Finklenburg and Mecke contains the methods of the photography and the analysis of band spectra, the application of wave-mechanics to a model with two centres, the treatment of the nuclear motion and rotation and the interaction of the rotation and electron motion in the model. The symmetry properties of molecules and their band structures have also been dealt with. The experimental results of band spectra of diatomic molecules have been collected and presented by Mecke in the next article. The chapter on the structure of polyatomic molecules on the basis of their spectra has been written by Mecke. The expressions for the frequencies of the XY_4 type given on page 353 requires modifications. In the case of acetylene, there seems to be no clear reason as to why $\delta\,(s)$ (inactive) should be 600 cm.$^{-1}$ except that it should interpret the 1329 cm.$^{-1}$ band in combination with $\delta\,(a)$ which is 729 cm.$^{-1}$ One may note that the band in question can be interpreted as $\nu_1\,(a)-\nu_0\,(s)$, and the 5250 cm.$^{-1}$ band as $\nu_1\,(a)+\nu_0\,(s)$, which is in conformity with Dennison's selection rules. A theoretical calculation of the frequencies based on the valence force system shows that $\delta\,(s) > \delta\,(a)$, thus throwing doubt on the assumption that $\delta\,(s)$ is 600 cm.$^{-1}$ The split of $\nu\,(a)$ in CBr_4 observed by Langseth may be explained as due to the resonance $\nu(a) \sim 2\nu(s) + \delta(s)$.

The volume contains clear articles by authoritative persons in the subjects dealt with.

PHOTO-ELECTRIC AND SELENIUM CELLS, THEIR OPERATION, CONSTRUCTION AND USES. By T. J. Fielding. (Chapman & Hall Ltd., London.) Pp. 140. Price 6s.

Next to the thermionic valve the photo-electric cell can claim to be one of the most outstanding inventions of the present century and has as universal an application as the former. The advent of the talking pictures and the more recent developments in television has created in the general public a keen desire for knowledge of this interesting device. The host of books that have appeared from time to time have failed to meet this demand since they are very often either too technical or at least demand a fairly good scientific background.

This little book although very limited in its purpose does justice to the intentions of its author, namely providing a brief

introduction to the use of light-sensitive devices in general. The author gives a lucid description of photo-electric and selenium cells and their construction, providing an average practical-minded person, data enough to construct some of the simpler type of selenium cells. The chapter dealing with talking pictures, television and its application to general industry will familiarise the reader with the principles and uses of the photo-cell. On the whole a very useful book for a beginner.

* * *

A SYMPOSIUM ON ILLUMINATION. By C. J. Webber Grieveson. (Chapman & Hall Ltd., London.) Pp. 229. Price 13*s*. 6*d*.

The book is a collection of lectures, each probably lasting for an hour or so, delivered by eminent men counted as authorities in the various branches of Illumination, as acknowledged by the Editor himself in his Note. It is certainly the best collection I have known. All that could be squeezed within the limited space allotted to the authors has been presented and made intelligible. The book can be recommended to every one who wishes to have a general idea of illumination for various purposes, which no engineer can afford to overlook in the modern rush for securing the best illumination with minimum expenditure.

M. HAYATH.

* * *

SHORT COURSES IN CHEMICAL THEORY. By E. P. Wilson. (T. M. Dent & Sons, Ltd., London, 1935.) Pp. viii+247. Price 3*s*.

There are very few publications which can be grouped along with the book under review in view of its somewhat novel treatment. The book is a collection of lecture-notes on chemical theory, highly useful to teachers and students alike. There are 22 chapters, dealing with the various aspects of chemical theory as taught in the Colleges to senior students. The notes serve to concentrate the attention on the crucial points of the subject. The book is a very useful addition to every College Library and is the outcome of the long experience of a *teacher*. Provision is made for the addition of examples, notes and diagrams in the book by the insertion of blank pages and the student is thus enabled to add to the information already contained in the book.

The Book is not, however, free from errors and from the point of view of the student this is to be regretted. To cite a few random instances: on page 87 under enzyme actions *emulsin* is printed as *emulsion;* one does not speak of *badly* ionised solutions (pages 143 and 144) but of *weakly* ionised solutions; sentences which have no relation to the context are often used as for instance, on page 171, under Osmotic pressure of colloids, it is difficult to understand the bearing of the sentence *Parchment paper (a colloid) gives best results;* on page 172 under electrical properties (5) the sign, =, used against KCl, $MgCl_2$ and $AlCl_3$ is incorrect, as the author intends to convey that 49·5 parts of KCl, 0·717 parts of $MgCl_2$ and 0·093 parts of $AlCl_3$ possess equal capacities for bringing about coagulation; on page 216, in providing examples for ionic dissociation in solutions we find that the dissociation of NaCl is represented as $NaCl \rightarrow Na + Cl'$, it should read $NaCl \rightarrow Na^{\cdot} + Cl'$. We should also like to see a glossary attached as it is somewhat difficult to understand the large number of abbreviations so often used throughout the text. In spite of these obvious errors, the book should prove highly useful to college students preparing for examinations.

STUDIES ON INDIAN ITONIDIDÆ (*Cecidomyidæ diptera*). By M. S. Mani. (Records of the Indian Museum, Calcutta, 1934.) Vol. 36, Part IV. Pp. 371–451. (28 Figures and 1 Plate.)

The study of galls interests the zoologist, as most of them are caused by the agency of insects and mites; the botanist, since the host plants often show a specific behaviour towards the causal agencies; and lastly, the plant pathologist, whose labours contribute towards a comparative pathology of tumours and cancers. In Germany, Hedicke, the Berlin Zoologist, Ross, the Munich Botanist, and Küster, the Plant-Pathologist at Giessen, have each shown how galls are worthy of attention. India, with its abundant supply of material for study, offers a virgin ground for the study of galls from all these three standpoints. Mani's monographic study of *cecidomyid* gall producers may be taken as a precursor of many more communications in this field. His study, under review, is not "Notes" or a sketchy study of the material he already found in the Calcutta Museum; he has personally collected most of the specimens described, even adding notes on the life-histories of the insects wherever opportunities permitted him to gather such information. This partly explains why most

of the insects named are derived from South India. We hope, inspired by Mani's example, others would also extend our knowledge of Indian gall-producing insects. Most Indian entomologists have confined their enthusiasm to the field for, when the question of naming new species had to be faced, they preferred acting as exporters for specialists outside to sift through the mass of crude material and thus enjoy the prerogative of creating names new to science giving their own study the stamp of a finished article. Mani has taken on himself such a responsibility and has given to the world several new genera, not to say of new species. A complete bibliography is given and grateful acknowledgment is made to several authorities. While his claim to originality is self-evident, it is equally apparent that a vein of modesty impregnates his style which makes his publication the more agreeable reading. The monograph ends with a single plate, containing photographic reproduction of five kinds of galls whose causal agents have been named by Mani; we only wish there were more of them. His pen and ink illustrations might have been better, particularly Fig. 19 on page 426, hardly does credit to the otherwise excellent study of Indian *Cecidomyids*. S. M.

* * *

A REPORT ON THE PROSPECTS OF PAPER MANUFACTURE IN HYDERABAD STATE. By Md. Moula Baksh, M.A. (Oxon.), F.L.S., and Khaja Nazamuddin, B.Sc., Tech. A.M.C.T. (Manch.) Pp. 71. (H. E. H. the Nizam's Government: Commerce and Industries Department Bulletin No. 4, New Series.) Price Rs. 2-8-0.

This report discusses the advisability and practical possibilities of establishing a pulp and paper mill in the Adilabad District making use of bamboo (*Dendrocalamus strictus*) available in the area as the source of fibre. It has been shown that good paper can be manufactured from these bamboos as is evident from the samples contained in the report.

The total production of paper in India at present is only 45,000 tons a year, while the import for the same period averages about 100,000 tons. All the relevant facts including cost of the raw materials have been discussed in detail in the report with a view to encourage some capitalist to start a factory and we hope that the expectations of H.E.H.'s Government will be realised in the near future. K. A. N. R.

* * *

Creatine et Creatinine par Fernand Kayser (Actualites Scientifiques et Industrielles No. 178. Hermann et Cie, Paris).—This little volume is divided into two parts. Part I is devoted to a description of the chemistry of creatinic substances and Part II to the biophysical studies. A clear and critical review of the existing methods of preparation and estimation, including some of the author's investigations, is given. There is an excellent bibliography in the end. The author complains of the insufficiency of the work done on these substances in France. C. S.

* * *

Metabolismes Des Corps Creatiniques par Fernand Kayser (Actualites Scientifiques et Industrielles No. 179. Hermann et Cie, Paris).—As in the previous number, this book also contains two parts. Part I treats of the metabolism of creatin and creatinin discussing in some detail the occurrence of creatin and creatinin in urine under physiological, pathological and experimental conditions. Part II deals with the pathological conditions only: the variation of creatin and creatinin in the affectations of the kidneys, muscles, the thyroid gland and in certain diseases like diabetes, gout, arthrites, etc. The prognostic value of determining these creatinic substances in the body fluids is indicated. Only eight pages are devoted for the pathological study, perhaps to keep in conformity with the shortness of these monographs. A good bibliography is appended. C. S.

Forthcoming Events.

The Geological, Mining and Metallurgical Society of India:—
Annual General Meeting, Monday, 2nd September 1935, 5-30 p.m.

1327-35.—Printed at The Bangalore Press, Bangalore City, by T. Subramania Aiyar, Superintendent, and Published by B. N. Sastri, M.Sc., A.I.C., A.I.I.Sc., for the "Current Science" Board of Editors, Indian Institute of Science, Hebbal Post, Bangalore.

Current Science

Vol. IV] SEPTEMBER 1935 [No. 3

CONTENTS.

The Indian Institute of Science.

IN view of the impending appointment of the second Quinquennial Reviewing Committee, a brief survey of the development and activities of the Indian Institute of Science, Bangalore, during its life of twenty-five years, may assist in creating sympathetic and enlightened public opinion. This will provide a favourable background, rendering the task of the Committee perhaps less tedious and more congenial; it may even be found indispensable to the formulation of a definite policy for promoting schemes of reform and expansion, such as the Committee may deem desirable to recommend on the conclusion of their labours. The first Quinquennial Reviewing Committee have, in more than one section of their report, drawn attention to the prevailing public ignorance of the work and resources of the Institute, and have also adversely commented on the general misconception among members of the Court regarding the economic activities of the different departments. Such ignorance and misunderstanding, if allowed to persist, would favour the growth of public prejudice affecting the character and fair reputation of the Institute, although there is ample testimony of honourable work steadily pursued in a spirit of disinterested service to the country. It is true that the Pope Committee reported in 1921 abundant evidence that there existed in many quarters "a strong feeling of disappointment and dissatisfaction" with the then existing condition of the Institute; and if such a feeling still prevails in the public mind, it must be almost entirely due to general ignorance of the steps that have since been taken to remove partially or entirely the causes which led the Committee to record the adverse comment. If, however, there is still a source of dissatisfaction either within the precincts of the Institute or outside, we think it must arise from defects inherent in its organisaton as well as from lack of a sound and definite policy, understood by all concerned, in regard to both the academic and the administrative spheres of this great foundation. In a short contribution on the Indian Institute of Science published in this *Journal* (October 1932), Alchymist observes that "with this provision (resources becoming available) the future, to which we now look for progress and expansion at least comparable with those of the last fifteen years, is hopeful". Manifestly the writer of the article is favourably

impressed by the advances made by the Institute during this period in the different branches of its activity. Sometime ago it was pointed out in an article in *Nature* (April 29, 1933) that "even if such an Institute were established in Great Britain, where the distances are not of the same continental order, it may be doubted if it would attract as many science graduates taking courses of advanced study and training for research as are now at Bangalore". This is a disinterested testimony to the increasing popularity and sound reputation of the Institute.

We have perused practically all the annual reports of the Council and have referred to almost all the volumes of the *Journal* of the Institute. They are probably the only authoritative documents which give information regarding the development of this institution, and when read in conjunction with the two Committee Reports reflecting the views and opinions of independent experts, we have all the materials necessary for forming a fairly correct judgment on the fundamental question of how far and in what manner the achievements of the Institute have fulfilled the aims and intentions of its founder, and also the intelligent expectations of the cultured public who look to the Institute for a lead in the economic and industrial life of the country. Judged by the ordinary academic standard, the Institute has a blameless record.

After briefly reviewing the administrative and financial matters of each year, Council Reports chronicle the departmental occupations of the Institute in a greatly abridged form, and their results are catalogued in the Appendices. To obtain a comprehensive and analytical view of the activities of the Institute, we propose to investigate the records for twenty years (1914–34), a period covered by the Pope and Sewell Committee Reports. During this period three departments, *viz.*, General and Organic Chemistry, Electrical Technology and Biochemistry,—were operating—and in 1934 the Department of Physics was instituted. The total volume of laboratory investigations undertaken in all these departments is reflected in the number of preliminary reports communicated to the Indian Science Congress, and in the number of papers published in the *Journal* of the Institute and in foreign scientific periodicals. In estimating these results, account must be taken also of consultative work in which the members of the staff and research scholars were engaged.

The evolutionary history of the
may conveniently be divided i
natural stages which we may ch

as the periods of exploration, consolidation and action. Between the years 1911 and 1921, the Institute was practically engaged in equipping itself for the duties of a " new Institution entirely novel to the country and therefore without a fund of experience on which to draw "—a factor which must impose a serious handicap on its emergence at once as a foundation rich in traditions and in spectacular achievements. The Council was engaged during these ten years in a very full and thorough discussion of the numerous administrative and academic problems arising from the resignation of Dr. M. W. Travers and of Professor Rudolf at the end of the session 1913–14 ; the schemes prepared by the special Committee of the Council involving considerable expenditure for equipping the new department of Applied Chemistry and for extending other existing laboratories ; the refusal of the Government of India to grant extra financial assistance owing to the War and the failure of the efforts of the Council to secure a Director who could also assume the duties of a professor of applied chemistry. In 1915, when the affairs of the Institute were passing through a critical phase, the Indian Industrial Commission was appointed, and when Sir Thomas Holland and Sir Dorabji Tata met Sir Alfred Bourne in the year 1916, a memorandum was presented to the Commission suggesting that the Institute should form a nucleus for the development on a large scale of an Indian Institute of Chemistry. This proposal was not in consonance with the resolution of the Government of India (May 1909) that " they were of opinion that the idea of combining in one Institution and entrusting to a single staff of professors, both the teaching of science and the experimental development of new industries, was open to the obvious criticism that these two objects were in no way connected." The Holland Commission accepted the Memorandum of the Council because they discovered that the Institute had departed from the resolution of the Government of India and from the aims and objects of the founder of the Institute, and a significant paragraph they wrote that, riginally projected by the late Mr. J. N. ata with the object of encouraging postraduate study and training for research a pure physical science, the Institute has, n the course of a comparatively short career, developed a distinct tendency towards the study of problems which are likely to lead to results of immediate economic value, rather than towards the pursuit of investigations of purely scientific interest. As a result of this bias towards chemical industry, the Institute was invited to cooperate with the Indian Munitions Board in the work which that Board had undertaken towards utilising local resources for war, and such assistance necessarily implied the temporary suspension of normal work in the departments. This co-operation finally led the Council to the conviction that " the Institute should concentrate effort on industrial chemistry and endeavour to secure further funds towards that end " and owing largely to the influence of this conviction great progress was made in the years 1916-18 towards associating the work of the Institute with that of the industrial departments of Government. The progress made in the applied branches of chemistry is reported in detail in a monograph issued by the Institute on the ceremonial occasion of unveiling the statue of Mr. J. N. Tata, and led the Council and Government to reconsider the future policy and lines of development. The Pope Committee was appointed in 1921 and their report introduced the second phase in the life-history of the Institute which we call the period of consolidation.

Dr. M. O. Forster (now Sir Martin Forster) was appointed Director of the Institute in 1922 soon after the publication of the Pope Committee Report. In less than three years of his assumption of duties, three professors retired on reaching the age-limit ; Dr. Alfred Hay in December 1922, Dr. Gilbert J. Fowler in 1924 and Dr. J. J. Sudborough in June 1925, the vacancies being filled by Mr. J. K. Catterson-Smith, Dr. R. V. Norris and Dr. J. L. Simonsen, respectively. Dr. Forster's time and energies were devoted to examining the administrative and departmental problems adumbrated by the Pope Committee and to exploring the means of implementing, in so far as might be possible, their recommendations. In the department of Biochemistry, Dr. Fowler had established a distinguished school of research in several applied branches, and Dr. Norris proceeded to found new ones. Relieved from the influence exerted by war-conditions, practically all the departments resumed the pursuit of investigations in pure science, maintaining, however, such *liaison* with industrial problems as opportunity offered. Dr. Forster's administration will be remembered chiefly as a period of consolidation of the

moral and material resources of the Institute, in accordance with the proposal of expansion outlined in the Pope Committee report. It was also the period which witnessed the rapid evolution of departmental activities which created a suitable atmosphere for the next phase of development. Before Dr. Forster relinquished his office in March 1933, the Sewell Committee had reported.

Sir Venkata Raman, the new Director, assumed charge of his duties almost immediately. It must be remembered that Sir Venkata Raman was a member of the Pope Committee and had sat in the Council of the Institute for over seven years. In this respect the new Director had an advantage over his predecessors, *viz.*, that he entered upon his duties with a complete knowledge of the work of the Institute such as few could claim to possess. But they were not confronted with the difficulties which Sir Venkata Raman had to encounter. He had soon to face a deficit budget. The Physics Department had to be constructed and equipped. The proposals of the Sewell Committee had to be considered. In the meantime Dr. H. E. Watson and Professor F. N. Mowdawalla proceeded to other appointments. Dr. Watson, who was the senior member of the Institute Staff, had by his energy and character elevated the Department of General Chemistry to an honourable position, and some of his researches had led to the establishment of industries. His departure from the Institute is undoubtedly a great loss. Professor Mowdawalla was a former scholar of the Institute where he had conducted several investigations in the Department of Electrical Technology, and his place is to be filled by Mr. Kenneth Aston. In the Council Report for 1934–35 the Department of Physics organised by Sir Venkata Raman is shown as having produced 39 papers, General Chemistry 9, Organic Chemistry 14, Biochemistry 49 and Electrical Technology 15, in other words the total output of research during this one year was 127 papers. We had almost a paper for every three days emanating from the Institute. This is research in [illegible] action.

The Pope Committee deplored that "the Institute has lost in efficiency by reason of the fact that its policy and lines of development have never been defined with sufficient precision" and an examination of the Council Reports since 1922 does not disclose any comprehensive and clearly defined policy directed to the promotion of the welfare and progress of the Institute and of its relation to the economic and industrial life of the country. Perhaps the most important question which the Institute will be called upon to settle is whether it will continue to provide preliminary training in scientific methods and knowledge in its departments and also to hold certificate and diploma courses in Electrical Technology, particularly in view of the fact that almost all the Indian universities have instituted research departments both in theoretical and applied branches of science, in which work of a very high order is conducted, manifest from the number of papers published in India and abroad. In most of the universities, post-graduate work involves a considerable amount of training in research methods, and the M.Sc. Degree is awarded on the submission of a thesis on an original problem. In view of the rapid strides that universities and government research departments are making in the field of research, the Indian Institute of Science has to shape its academic policy to suit the altered conditions in the country.

The essence of this policy, as we conceive it, is that the Institute must find facts, while the public and government must find out how to use them. One of the main articles of such a policy would be to launch a campaign to convince the new legislatures and other bodies who control finance, that research is wealth, and that the greatest tributaries to it are chemistry and physics, through their contributions to agriculture, medicine, metallurgy and the entire range of manufacturing occupations. The second factor in this policy is to insist upon public recognition of the fact that the prosperity of a country in a competitive civilisation depends not so much upon the control of natural resources as upon the control of scientific processes. The work of the Institute in the field of fundamental research and industrial research should no longer be permitted to remain an inscrutable mystery to statesmen and administrators whose position in public life and whose influence in the legislative councils would be a material agent in establishing new research laboratories. The Institute is essentially a single organism, whose health and functional efficiency depend upon the harmonious co-operation of its different members, and in order to secure such co-ordinated effort and infuse a sense of collective responsibility,

the different departments must develop mutual interests and remove the spirit of exclusiveness. This is best done by the establishment of borderland branches of science, which would bind the several units into a single corporate body with common aims and purpose.

The question of the status of the Institute is discussed by the Sewell Committee. They have stated "that the Institute ought always to be in a position to provide such opportunities as cannot be obtained anywhere else in India; that it should do what no other institution can do; that it should maintain a position of pre-eminence; that it should acquire even a world reputation and that it should become a place of reference." The path to attaining this ideal is also indicated in the report, *viz.*, the personnel of the directorate, professoriate and staff, to which we would add finance. These admirable sentiments, however, are not in consonance with the theory elaborated by the Committee regarding the sources of revenue to be explored by the Institute. It seems to us that the preservation of the All-India or international character of the Institute depends upon the regional origin of its finances, its staff and students; and any suggestion of contribution by the provinces in proportion to the benefits received by their scholars must militate against the All-Indian status of the institution. On the other hand, contributions based on the financial capacity of each province irrespective of other considerations will invest the policy and outlook of the Institute with a national character. Each British Province and each major Indian State might endow a chair and support the laboratory attached. The late Mr. J. N. Tata never contemplated personal or communal benefit from the Institute which his munificence founded. The Institute is the cultural rallying point of the Indian Nation, and its structure is an indivisible unit. If the provinces, the Indian States and the industrial magnates consider it their patriotic duty, rendered in a spirit of pure altruism, to create and support associate professorships, readerships and lecturerships in appropriate branches of science, then it may be possible to release the funds of the Institute more freely for developing its international reputation, by inviting scientists of outstanding eminence such as the Sewell Committee contemplate, to associate themselves with the life and work of the institution. If it were only possible to induce such men to come to India —and it may not be difficult provided we have the resources—the universities, the government scientific departments and the industries would be glad to secure their co-operation and only then would the Institute be in "a position to do what no other Institution could do". It is gratifying that, with the limited funds at his disposal, Sir Venkata Raman has already taken the first step in this direction by inducing the Council to invite Professor G. Hevesy and Dr. Max Born to stimulate the work of the Institute; further development of this great institution must depend upon the financial support of provincial governments and of the Indian States.

Academy of the Natural Sciences of Philadelphia.

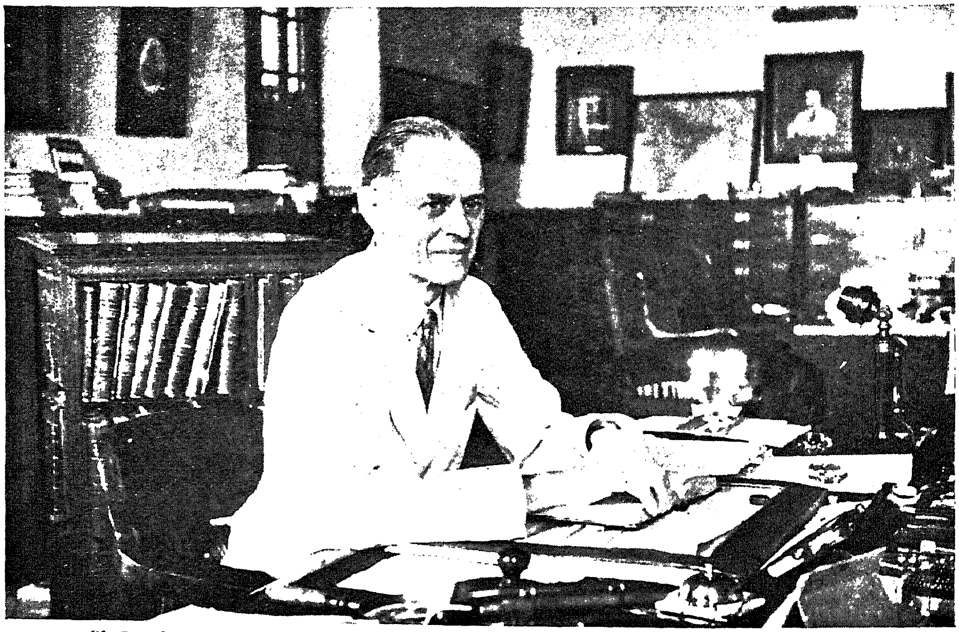
MUSEUM workers all over the world are familiar with the high standard of publications issued by the Academy of Natural Sciences of Philadelphia, which is maintained wholly by private endowments and contributions from members and friends. This Academy was founded in 1812 and has done great service in stimulating research in natural sciences in almost a century and a quarter of its existence. The 86th volume of its *Proceedings* for 1934 has been recently issued. It contains 17 contributions from well-known workers. Of these 15 are on zoological subjects dealing with Mammals, Birds, Reptiles, Amphibians, Fishes and Molluscs, and two small ones on botanical subjects. The interesting feature of this volume is that it contains contributions about the Zoological Results of the Third De Schauensee Siamese Expedition, of the Matto Grosso Expedition to Brazil in 1931, and Dolan West China Expedition of 1931. These expeditions account for 7 papers out of 15. Another remarkable feature of the series is that separates of the contributions presented in its *Proceedings* can be purchased at a small cost. There is a good index to the genera and species described and referred to in the volume. The full volume comprises 589 pages and 23 plates, mostly of molluscs. It is further illustrated with numerous drawings in the text. The price of the full volume is \$5·00 to subscribers and \$6·25 to others.

Sir Lewis L. Fermor, Kt., O.B.E., D.Sc., A.R.S.M., F.R.S., F.G.S., F.A.S.B., M.Inst.M.M.

AFTER thirty-three years' distinguished service to India, Sir Lewis Fermor will be retiring this month from the Directorship of the Geological Survey of India, and India will be losing one of her most distinguished scientists. We take this opportunity of paying our tribute to one who has laboured so well for the cause of Science in India.

Trained as a geologist at the Royal School of Mines under Prof. J. W. Judd, with a strong interest in metallurgy, Sir Lewis Fermor was appointed to the Geological Survey of India in 1902, at the time that Sir Thomas Holland assumed the Directorship of the Survey. His promise of exceptional ability was recognised when he was promoted to the grade of Superintendent in 1910, at the early age of 30.

Sir Lewis Fermor's first introduction to Indian Geology was given to him by the late Mr. E. W. Vredenburg, whom he accompanied into the field in Central India. It was on this occasion that Sir Lewis first came into contact with manganese ore deposits in the field, and it was probably due to this that in the following year Sir Thomas Holland, thinking it advisable to examine scientifically what was then already a flourishing industry, deputed Sir Lewis Fermor to investigate the manganese ore



Sir Lewis L. Fermor, Kt., O.B.E., D.Sc., A.R.S.M., F.R.S., F.G.S., F.A.S.B., M.Inst.M.M.

deposits of India. It is probable, however, that Sir Thomas Holland never visualised that this work would take six years to complete, and lead to the publication of a monumental memoir running to 1294 pages. In this great work, by which Sir Lewis is still best known outside India, manganese was treated from almost every point of view; and hidden away in this memoir there is a wealth of original observation, concerning not only manganese itself but also many related geological problems, which has frequently been overlooked. Of the many valuable results accruing from this work, one may specially be mentioned, since it proved to be of direct help to the mining companies which were engaged in winning the ore. This was the recognition that the folded sheets of manganese ore had generally a marked pitch, and that the direction of this pitch could be determined in a single exposure by observing the groovings developed on the bedding planes of the associated rocks. The recognition of this principle must have saved the companies many thousands of rupees, previously lost through

their inability to understand the probable underground course of the ore bodies.

The number of papers already published by Sir Lewis Fermor is well over 80. Of these one may be picked out as of particular scientific interest. As a result of studying the rocks of the Eastern Ghats, which are rich in garnet and of high density, it occurred to Sir Lewis to enquire into the reasons for rocks in certain areas being composed of minerals of high density, such as garnet, whereas elsewhere rocks of similar chemical composition are composed of minerals of lower density. This led him to suggest that below the plutonic zone of granites and gabbros there occurs an infra-plutonic shell of similar bulk composition but composed of denser minerals, of which the chief is garnet. This shell was regarded as being a cushion upon which the isostatic operations of the earth have their foundations ; for it would only require a release of pressure over any given portion of the infra-plutonic shell to allow the liquefaction of that portion of the shell under the high temperatures present. In this way he was able to offer an explanation of many geological problems, such as isostasy, magmatic differentiation, the origin of earthquakes, and even the constitution of meteorites. It is unfortunate that this work, published so long ago as 1914, has not been followed up in greater detail. At the moment it is being revived in connection with the origin of earthquakes, and one Japanese seismologist has recently supported the hypothesis, following up R. D. Oldham's suggestion that earthquakes are due to the sudden transformation of rocks of the infra-plutonic zone into less dense forms in the manner indicated above, a change, which, being endothermic, may take place with explosive rapidity.

In 1911 a detailed survey of the Archæan rocks of the Central Provinces was begun, and Sir Lewis Fermor was placed in charge of the party. He at once initiated the mapping of these very old rocks in a more detailed manner than had ever before been attempted. This work has continued intermittently since that date, but it is unfortunate that owing to official administrative duties Sir Lewis has not yet had an opportunity of publishing his own results. We may perhaps express the hope that in the quieter times ahead opportunity may be found for bringing this valuable work to fruition.

During the War Sir Lewis Fermor rendered valuable service on deputation to the Railway Board, during which time he investigated the Bokaro coalfield, and the Karanpura and Talchir coalfields, while he also went on deputation to the Indian Munitions Board. The value of this work received recognition at the hands of the Government of India when, in 1919, he was made an O.B.E. For his contributions to theoretical geology he was awarded in 1921 the Bigsby Medal of the Geological Society of London, while in 1934 he was elected a Fellow of the Royal Society.

During his long service in India, Sir Lewis Fermor has been President of the Mining and Geological Institute of India, President of the Geology Section of the Indian Science Congress, General President of the Indian Science Congress, and now, at the time of his retirement, he is President of the Asiatic Society of Bengal, and President of the National Institute of Sciences of India, the oldest and the youngest academies of scientific learning in India. To each of these Institutions he has delivered inspiring and original addresses, which have indicated the wide scope of his outlook.

Sir Lewis Fermor was made Director of the Geological Survey in 1932. During his tenure of the Directorship it has been a great disappointment to him that his Department, for adventitious reasons, suffered so severely during the retrenchment carried out by the Government of India in 1931-32. His untiring advocacy of the value of the Geological Survey to the prosperity of India has, however, resulted in the partial restoration of the cadre of his Department. In the Birthday Honours of this year the honour of Knighthood was conferred upon him for his long and distinguished services to India, a reward, however, which he himself likes to regard as a recognition by the Government of India of the value of his Department to this country.

Great as have been Sir Lewis Fermor's achievements in the development of India's mineral resources and in the domain of pure science, it is probable that many will regard his unremitting endeavours last year to unite scientists in India, when there appeared the possibility of an undignified rupture, as his most happy achievement. The tact and patience which he displayed as Chairman of the Indian Science Congress Academy Committee revealed to many a new aspect of his character, which finally resulted in the formation of the National Institute of Sciences of India, inaugurated on January

7th, 1935, by H. E. Sir John Anderson, the Governor of Bengal, with Sir Lewis Fermor as the first President.

In bidding farewell to Sir Lewis Fermor, it would be ungracious to omit a reference to Lady Fermor. During the three years that she has been by his side in India, she has, by her charm and understanding, endeared herself to all who have had the good fortune to come in contact with her, and especially to every member of Sir Lewis Fermor's own Department. We hope that the years that are ahead of them may be rich in achievement and filled with prosperity and happiness.

Industrial Intelligence and Research in India.

By N. Brodie,

Director, Industrial Intelligence and Research Bureau.

THIS article deals with the formation and activities of the organisation recently set up by the Government of India to deal with industrial intelligence and research. The importance of industrial research under present-day conditions is universally recognised and Government bodies of one sort or another exist in all the major industrial countries but industrial intelligence is not so much in the foreground and, by laying some stress on this, India strikes out a new line. Nevertheless, although not given the same emphasis in other countries, industrial intelligence is generally, perhaps always, an important accompaniment of industrial research and most industrial research organisations have some arrangement for intelligence work, frequently in the form of a special department dealing with this work.

In India Industries is a transferred subject and therefore, so far as British India is concerned, a matter for the Provincial Governments. Most Provincial and many State Governments have instituted Departments of Industries, generally under the charge of an officer designated the Director of Industries. Several Departments of Industries, both in the Provinces and in the States, maintain industrial laboratories in which research work is carried out. For some time past it has been generally felt that the activities of these different laboratories suffer from lack of co-ordination and at the Fifth Industries Conference, held in July 1933, this question was raised in a specific form and it was recommended that "some central co-ordinating authority should be set up for the collection and dissemination of industrial intelligence, co-ordination of research and the organisation of industrial exhibitions". This recommendation was accepted by the Government of India and it was decided that a body of this type should be formed and attached to the Indian Stores Department, a Department which has much contact with industrial matters in India. The Chief Controller of Stores, Sir James Pitkeathly, drew up a scheme which was placed before and accepted by the Sixth Industries Conference held in July 1934 and subsequently sanctioned by the Government of India. This scheme will be found described in detail in bulletin of Indian Industries and Labour No. 52 giving the proceedings of the Sixth Industries Conference.

In accordance with Sir James Pitkeathly's proposals the Government of India sanctioned, with effect from the beginning of the present financial year, the formation of what is known as the *Industrial Intelligence and Research Bureau.* The staff of the Bureau consists of a Director, an Assistant Director and the necessary technical and clerical assistants. It is attached to the headquarters of the Indian Stores Department and is therefore located at New Delhi and Simla. At the same time a Research Branch was formed at the Government Test House, a laboratory situated at Alipore (Calcutta), which is also under the control of the Indian Stores Department. The staff of the Research Branch consists of a Research Officer, an Assistant Research Officer, 8 Chemical and Physical Assistants and clerical and menial staff.

The programme of the Research Branch and all important matters of policy involving the Bureau are brought before the Advisory Council for Industrial Intelligence and Research. This Council consists of the Directors of Industries or corresponding officers of the Provincial Governments and of seven Indian States, representatives of different Central Government Departments, four non-official members nominated by the Government of India and non-official

members nominated by each of the Provincial Governments. The Chairman is the Joint Secretary to the Government of India, Department of Industries and Labour and the Director of the Bureau acts as the Secretary. By the inclusion among the members of the Advisory Council of a considerable non-official element, it is hoped that the Council will be able to obtain the assistance of Industrialists and business men and hence keep in touch with the practical problems of industry.

The Advisory Council held its first meeting in Simla on July 8th and 9th, 1935. As a first step towards the co-ordination of the research activities of the different Provincial and State laboratories it was decided to form a Committee to deal with research in two subjects with one or other of which, as it happens, every such laboratory has, to some extent at least, interested itself. These are: (1) fatty oils and soap, and (2) essential oils. A second Committee was appointed to consider the question of the allocation of prizes for papers for which purpose a sum of Rs. 10,000 a year has been set aside. The programme of research for the Government Test House was considered in detail and various researches were agreed to. As a step towards forming a judgment of the problems of the glass industry in India it was recommended that the Bureau should undertake a survey of the glass factories in India and publish a review of the whole position. The important question of industrial standardisation was considered and it was recommended that specifications used by the local governments and the Railway and Indian Stores Department should be sent to the Bureau for examination. The object of this is to ensure that specifications are so framed as not to exclude materials made in India.

It will be seen that the organisation for industrial intelligence and research consists of three distinct but closely linked parts, *viz.*, the Advisory Council, the Bureau and the Research Branch of the Government Test House. The Advisory Council deals with broad questions of policy in all matters affecting the organisation as a whole. The present intention is that it should meet once a year and it has been proposed that it should meet at different important centres in rotation. Matters sufficiently important to be brought before the Council which cannot await the annual meeting are dealt with by correspondence. The Bureau acts as the secretarial body of the Advisory Council and implements its recommendations. On the research side it is responsible for drawing up detailed schemes of the projects accepted by the Council. On the intelligence side it deals with requests for industrial information forwarded by Directors of Industries. This is the normal channel through which enquiries are received. The Bureau is accumulating a library which it is hoped will be reasonably comprehensive as regards the matters with which it deals. The Research Branch of the Government Test House is concerned solely with carrying out research work on the lines laid down by the Bureau on the authority of the Advisory Council. The association with the existing organisation of the Government Test House will undoubtedly be of much value to the new branch, since the Government Test House is well equipped and its officers have considerable experience of industrial problems. The subjects for research chosen by the Council include :—

(1) The investigation of the behaviour of paints of different formulæ on exposure to atmospheric and other influences. A considerable amount of work has previously been carried out by the Government Test House on this subject.

(2) The investigation of the behaviour of vegetable oils when used for the lubrication of internal combustion engines. For this purpose the Government Test House will be equipped with a petrol engine of the motor car type together with the necessary cooling devices and other accessories and a dynamometer for measuring the energy output.

(3) The investigation of the behaviour of Indian cement when tested according to the methods proposed to be adopted for the new British Standards Specification and also the behaviour of Indian sands in these tests.

(4) The investigation of various problems affecting the use of lime as a building material.

(5) The investigation of the effect on the properties of dry cells of systematic variation of composition. For this purpose a constant temperature plant will be installed. A considerable amount of work has previously been done in India on dry cells, the manufacture of which appears to be a promising small industry, but a systemat[illegible] investigation of the type proposed nec[illegible] tates working at a fixed tem[illegible]ion of

Otherwise variations of performance arising from differences of composition are, unless they are very marked, obscured by the large temperature effect shown in the watt output of such cells.

(6) A systematic investigation of the different Indian sands and felspars which appear to be suitable for glass making. If use can be made of felspars found in India, one of the problems affecting the glass industry, *viz.*, the fact that it depends on imported soda, will not be solved but at any rate lessened. Various analyses of Indian sands are available but the Tariff Board in its recently published report expresses the opinion that the data were not sufficient. Less attention appears to have been paid to the possibly important question of the utilisation of felspars.

To provide for the expenses of the Bureau and the Research Branch of the Government Test House, the Government of India have sanctioned the expenditure of a sum of five lakhs of rupees spread over three years. The exact apportionment of this sum cannot at present be foreseen but probably, in very round figures, some three lakhs will be spent on the Bureau, including the award of prizes, and two lakhs on the Research Branch of the Government Test House.

The organisation described has not been in existence long enough for it to be possible to forecast with any confidence what its future is likely to be, but it is hoped that the brief account given will give an idea of the lines on which it is at present proposed to work.

Exploration of the Upper Atmosphere by means of Sound Waves.

By K. R. Ramanathan,
Indian Meteorological Department, Poona.

THE maximum height which balloons carrying self-registering instruments have reached is about 35 km. A limit to the attainable height is set by the properties of the fabrics out of which balloons can be made. With improved fabrics it is possible that this height may be exceeded, but this is a problem for the future. An altogether different method for studying the physical conditions in the layers of the atmosphere which lie immediately above the reach of balloons is by the use of sound-waves. Beginning from 1904, when Van d. Borne discussed the propagation of sound-waves proceeding from an explosion of dynamite in Westphalia, the subject has developed considerably. During the second Polar Year, August 1932 to August 1933, a special series of explosions were arranged in Holland and also in the Polar regions. The results of this and other previous work are collected together in a special number of the *Zeitschrift für Geophysik* published last year. A lucid resumé of the present position of the subject and an account of the work done in England in the last decade is contained in the Symons Memorial Lecture delivered in March 1935 before the Royal Meteorological Society of London by Dr. F. J. W. Whipple, the Director of the Kew Observatory, and the foremost worker on the subject in Britain.

Some of the principal features of the propagation of sound from a loud explosion which can be inferred from aural observations can be summarised as below. Surrounding the source of sound, there is a region of 50–60 km. radius in which the intensity of the sound falls off gradually with distance; beyond 50–60 km. the sound is not audible. Going farther from the source, the sound again revives, often sharply, at a distance which may vary from 100 to 200 km. This second "zone" of audibility is often about 100 km. wide. If we calculate the velocity of the sound heard in this region from the distance from the source and the time between the explosion and the time of hearing the report, the computed velocity is found to be much smaller than the velocity corresponding to the temperature prevailing in the lower atmosphere. An explanation of these peculiarities was offered by Van d. Borne himself. In the immediate neighbourhood of the source the sound travels in the lower atmosphere, but that received in the second zone comes not directly, but by a longer path after reflection from the upper atmosphere. Timing the reception of the sound at known distances enables the determination of the delay in making the detour and the results of observations show that the sound gets reflected at heights ranging from 35 to 45 km. in the atmosphere.

Occasionally, the second zone of audibility is followed by yet a third one with a second zone of silence between. The sound received in this zone is due to waves reflected twice from the upper atmosphere and once from the ground.

The hearing of gun-fire at great distances from the battle-front during the European War in 1914–18 provided much interesting new information. It was found that during summer in Europe sounds travelled to great distances to the west, while during winter, they could be heard much farther in the east. The audibility at the same distance in different directions was not also the same. Further progress in the subject came with the organisation of pre-arranged explosions and the development of the technique for the reception of the sound. In the Continent of Europe, special explosions were made by the destruction of surplus munitions and in England advantage was taken of the firing of artillery guns. The receiving instruments used in Germany are based on the principle of magnifying optically the movements of a light piston or stretched membrane at the mouth of a resonator; in England, Tucker's hot-wire microphone is used. The arrival of waves is recorded at a number of places at distances going up to 300 or 400 km. from the source and advantage is taken of the broadcasting organisation to send wireless waves every second for time-marking purposes. An important quantity that is determined in recent work is the angle which the arriving wave makes with the horizontal; this gives the velocity of sound at the topmost part of the trajectory, being equal to $v \sec i$, where v is the velocity of sound near the ground and i the angle which the trajectory makes with the ground. The angle generally lies between 10° and 35°. Knowing the velocity of propagation at the topmost part of the trajectory and the distribution of temperature in the first 30 km., it is possible with certain simple assumptions to complete the trajectories of the sound in the upper atmosphere. The assumptions usually made are that up to a certain height, the velocity of sound in the stratosphere is constant and that above this it increases rapidly. In recent calculations, the influence of wind in the accessible layers of the atmosphere is also taken into account. The calculations show that the downward movement of sound begins at 35–45 km. The increased velocity in the upper atmosphere implies either an increase of temperature or a decrease of molecular weight. For various reasons, the former alternative is believed to be true in the layers under consideration.

The average distribution of temperature in the upper atmosphere over Europe in summer deduced from the collected results of these experiments is shown in Fig. 1.

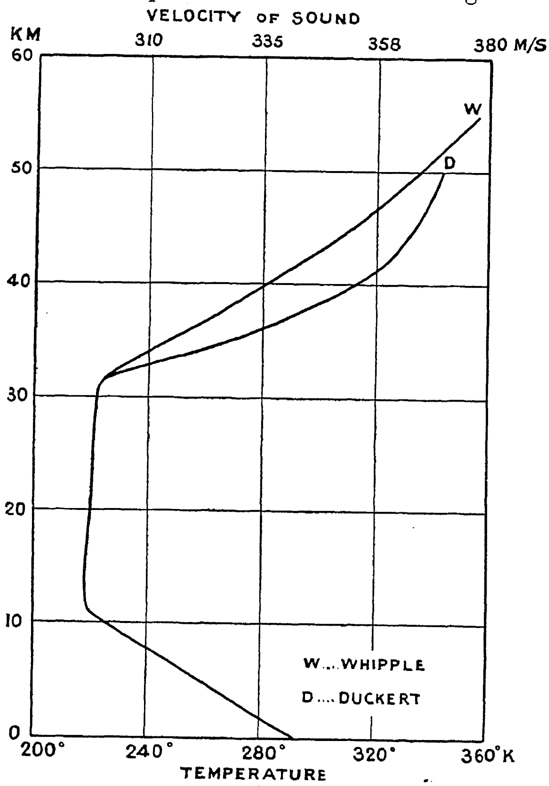


Fig. 1.

The marked difference between summer and winter as regards audibility at stations east and west of the source has already been mentioned. The records of self-registering instruments also show differences of times of travel of sound in different directions which can only be explained by large velocities of the order of 20–40 metres per second in the stratosphere, easterly in summer and westerly in winter. Many other facts such as the movement of persistent meteor trails and luminous night clouds support the same conclusion.

A reason for the strong westerly and easterly winds in winter and summer respectively in European latitudes has been put forward by Whipple. The results of sounding balloon ascents made at Abisko in Lapland during the years 1921 and 1929 showed a remarkable annual variation of

temperature in the stratosphere, the mean temperature at 18 km. changing from 235° A. in June and July to about 210° A. in November to February. This very large change of temperature causes a seasonal change of pressure gradient between the temperate and polar regions causing easterly winds in the stratosphere in summer and westerly winds in winter.

The rise of temperature above 35 km. in the temperate latitudes is generally attributed to the absorption of ultra-violet solar radiation by ozone in the region 2,900–2,200 A.U. Taking the distribution of ozone in the vertical as worked out by Dobson, Götz, and Meetham, and assuming that the main radiating substance in the stratosphere below 50 km. is water-vapour (in such quantities as we may reasonably expect to be present) and carbon dioxide, it is easy to explain the course of temperatures over Europe deduced from experiments on the propagation of sound from explosions. But the fact that even in Polar regions in winter where the atmosphere has not received solar radiation for weeks, the phenomenon of anomalous propagation of sound is observed shows that the above explanation is insufficient.

Observations of the anomalous propagation of sound in the tropical atmosphere are practically absent, the only known instance in low latitudes being those of an explosion of a train-load of gelignite in South Africa in July 1932, when the sound was heard at a distance of 500 km.

It is obvious that the detailed investigation of the propagation of sound to great distances in low latitudes cannot fail to yield results of fundamental importance to the Physics of the Atmosphere. If the sympathetic co-operation of the Indian Military Department can be secured, the problem does not appear to present serious difficulties. Side by side with this, the problem of the vertical distribution of ozone in our latitudes would also have to be investigated.

The Nature and Origin of Insect Colours.

By M. S. Mani.

(From the Laboratories of the Zoological Survey of India, Indian Museum, Calcutta.)

THE nature, origin and significance of the colours of insects have attracted the attention of workers from very early times. Within recent years, great advances have been made along various directions. In this note attention is directed to the recent advances in the subject, in so far as they relate to the nature and origin of insect colours.

The great varieties of colours and markings exhibited by insects naturally fall into two groups: (1) Structural colours, and (2) Pigmentary colours. Structural colours are due to light scattering, reflection, refraction and diffraction effects, as a result of certain peculiarities in the minute structure of the integument of insects and not to special pigments. The pigmentary colours, on the other hand, result from some definite chemical substance such as chlorophyll, melanin, etc. Some insects, as the metallic coloured beetles, owe their brilliant colours to structural peculiarities, while in others like the larvæ of some Lepidoptera, the colours are due to pigments. In most insects, however, combination colours are more prevalent than purely structural colours; pigments exist side by side with structural peculiarities which by themselves are also colour producing. This, for instance, is the case with *Ornithoptera poseidon* investigated by Onslow[1] who found that the green colour of this insect results from a combination of yellow pigment with a structural blue.

It is very difficult to elucidate the origin of structural colours of insects and the results of recent workers differ in several important respects. The white colour of insects is due to the absence of any special pigments and results from the minute structural details of the cuticle irregularly scattering the light waves by multiple reflection and refraction. All the white colours of insects are ultimately to be traced to this source, though it is believed that in a few insects the presence of uric acid in a finely divided state is the cause of white colour. It has, however, been shown that in such cases even after the removal of the uric acid by treatment with dilute alkalies, the white colour remains unchanged. That the white is due to structural peculiarities is

[1] Onslow, H., *Biochem. Journ.*, 1916, **10**, 26.

further shown by the evidence obtained by the disappearance of the white when the air in contact with the white parts is replaced by a colourless liquid of nearly the same refractive index as the chitin of insects. The original white is fully restored when the liquid is removed and the chitinous part dried. The recent researches of Mason[2] further show that a colourless cuticle with an irregular reflecting surface is generally white.

The other structural colours of insects are of two types: (1) the iridescent or the so-called "metallic" colours, and (2) the non-iridescent or the non-metallic colours. The elytra of the metallic coloured beetles, the bodies of the enamelled Rose-chafers (*Cetoniids*) and the metallic Chalcids and the scales of certain brilliantly coloured Butterflies, etc., show marked iridescence. The non-iridescent colours are found only in the larvæ of some Lepidoptera.

Considerable attention has, within recent years, been devoted by such workers as Onslow, Suffert and Mason, to the investigation of the iridescent colours of insects and various causes have been regarded as responsible for them. It is now believed that the iridescent colours of insects are caused by:

(i) Diffraction effect due to the presence of a grooved surface or "grating".

(ii) Interference at surface due to simple or multiple films.

(iii) Tyndall effect or scattering of light waves by particles with diameters less than the wave-lengths of light.

(iv) Selective reflection of a narrow band of the spectrum from an opaque and highly reflecting surface.

According to Mason,[3] the brilliant iridescence of the elytra of the Lamellicorn beetle, *Sericea sericea*, is due to the diffraction effect produced by the fine striæ, about 20,000 per inch, running transverse to the length of the elytra. The iridescence of this beetle, owing to the grating being external, is transferable to collodion impressions. There are other insects recorded by Onslow[4] in which the iridescence is not transferable. This, for instance, is the case with the butterfly, *Morpho cypris*, whose scales are brilliantly iridescent. These instances, however, appear to be exceptions among insects and the general conclusions of Onslow,[4] Suffert[5] and Mason[3] are opposed to the view that diffraction plays an important part in insect colouration. Onslow has further observed instances where the collodion impressions of the gratings are brilliantly iridescent while the insects themselves are not.

Diffraction theory is entirely inadequate in the case of the non-pigmented wings of the Dragon flies, where no grating has yet been shown to exist. The view of most investigators in such cases is in favour of the interference theory. Mason's[3] work seems to show that the iridescence in this case is explainable on the basis of multiple thin films separated by a material of different refractive index, a phenomenon which was comprehensively dealt with by Rayleigh.[6] The recent preliminary studies of the writer indicate that the purplish iridescence of the wings of some species of the Chalcid genera *Leucospis* and *Dirhinus* is also due to interference. Scale iridescence is also explainable on the same lines. The result of swelling and compressing the scales and of permeating them with liquids of the same refractive indices seems to lend support to this view.

Mason[3] divides iridescent scales into three types: (1) *Urania* type, (2) *Morpho* type, and (3) *Entimus* type. In the first type of scales all the colour-producing films are parallel to the surface of the scale, overlaid by rib-like structures. The multiple films are either in the upper or the lower lamina of the scale. Suffert[5] demonstrated that in the second type of scales the reflecting films are situated in the rib-like structures themselves at an angle to the base of the scale, *i.e.*, inclined to it. The optical result of such a structure is a brilliant metallic blue. In the third the films are in the interior of the scales and inclined in different directions, so that corresponding colour patches are produced. This type is seen in various species of the Diamond beetles of the genus *Entimus*. Biedermann[7] and Mallock[8] explained the iridescence of these beetles wholly by the theory of thin films. Michelson,[9] on the other hand, held that stratified

films could not be responsible for the varied colour of scales, and supposed that the effect must be due to diffraction by an internal grating of the scale. He was, on theoretical grounds, able to calculate that the grating should comprise 5,000–10,000 striæ per centimetre and this agreed with actual counts. Onslow postulated that to satisfy this theory it was necessary to suppose that the gratings are of the saw-tooth type, as all the light is concentrated in one spectrum. He did not, however, accept diffraction as the sole cause but concluded that interference by thin films also must play a part in the production of iridescence. Mason,[3] on the other hand, agreed with the earlier workers in explaining iridescence on the basis of the stratified films alone.

Mason's[2] work also seems to show that the blue colour of certain insects, such as the Dragon flies, can be interpreted on the basis of Tyndall effect. According to this view the colour is due to the scattering of light by minute particles of a transparent substance immersed in a medium of a different refractive index to their own. When the size of particles is small as compared with the wave-lengths of light, the shorter waves are scattered, while the longer ones pass unhindered, and the scattered light is of a blue colour.

Experimenting with highly iridescent beetles, Onslow[4] concluded that in some beetles at least the surface film absorbs only a certain part of the spectrum, while the rest is strongly reflected. According to this view the iridescence of these beetles is a case of selective reflection. It is not, however, clear how such a film is formed and Mason[3] has discussed at length the weak points of this theory. According to him the colours of the metallic beetles and the enamelled Rose chafers result from multiple stratified films of considerable thickness lying on the integument. The colours are further supposed to be modified by the action of certain rod-like structures which are arranged in the cuticle perpendicular to the surface.

The main work on the pigmentary colours of insects is perhaps that of Poulton,[10] whose experiments with Lepidopterous larvæ are well known. Recent workers such as Przibram,[11] Glaser,[12] Palmer[13,14] Hungerford,[15] Wigglesworth,[16] Knight,[17] Thompson[18] and Brindley[19] have also contributed materially to our knowledge of the various pigments of the insects.

The pigments most commonly met with in insects are (1) chlorophyll and its derivatives, (2) hæmoglobin and allied pigments, (3) pigments of protein origin, and (4) pigments with purine bases. The spectroscopic investigations of Poulton indicated the presence of chlorophyll and its derivative xanthophyll in the blood and integuments of some caterpillars, such as the green larvæ of some moths. These pigments are absorbed with the food, and do not undergo any marked changes in the blood of the insect. Przibram[11] is opposed to Poulton's conclusions. He does not agree that spectroscopic evidence alone is sufficient to establish the presence of chlorophyll in insects and stresses the necessity of chemical tests. He proposes a new name "Tiergrun" for the green colour of animals. Gerould,[20] however, criticises Przibram's chemical tests as inconclusive and in general agrees with Poulton. In this connection the work of Gräfin von Linden[21] is of special interest; she found that the red and yellow pigments found in the wing scales of the butterflies of *Vanessa* spp. are derived from the chlorophyll absorbed during larval life. The red and yellow colours of Coccinellid and Chrysomelid beetles and the red colour of the Reduviid bug, *Perillus bioculatus*, have been shown by Palmer and Knight[14] to be due to the carotin derived from their food. They also demonstrated the presence of anthocyanin in the vermilion-coloured Aphid, *Tritogenaphis rudbeckiæ*; a similar conclusion was arrived at by Glaser[12] in regard to the red Aphid, *Pterocomma smithiæ*.

Hæmoglobin is of rare occurrence among insects and is only found in some larvæ

of the Dipterous family Chironomidæ. It has recently been found by Hungerford[15] in the Notonectid, *Buenoa*.

The most important pigment of protein origin found in insects is melanin; it is commonly found in many groups. Of the pigments with purine bases, uric acid and its derivatives have been shown by Hopkins[22] to be the cause of white and yellow colour of wings of butterflies of the family Pieridæ.

The Mathematical Theory of a New Relativity.*

BY SIR SHAH MUHAMMAD SULAIMAN—A CRITICAL REVIEW.

§ 1. In the two papers published in the *Proceedings of the U. P. Academy of Sciences*, the author claims to have given a modification of Newtonian kinematics and Newtonian dynamics which not only yields all the results deducible from relativity but disproves the assumptions of relativity by deriving results more in accord with observation. He further derives some equations which, superficially, at any rate, look like generalisations of relativistic equations and then deduces Newton's forms as first approximations and Einstein's as higher ones. The first article consisting of Chapters 1 and 2 is devoted mainly to the theory of gravitation and the second article consisting of Chapters 3, 4 and 5 deals with Cosmology and questions of special relativity.

The first of these articles was included by Shapley[1] as "one of the high lights of Astronomy during 1934" in his remarks at the annual dinner of the American Association of Variable Star Observers on October 20, 1934.

It is not clear from Shapley's speech whether such a reference was based on a critical study of the article in question or on a tacit assumption, at its face value, of the claims put forward by the author. Quite recently this article has been critically reviewed by D. R. Hamilton,[2] who, confining himself to Sulaiman's explanation of the advance of perihelion, comes to conclusions which suggest that Sulaiman's work is absurdly erroneous. On the mathematical side not much notice has been taken of the work, the *Zentralblatt für Math.*,[3] satisfying itself with a bare mention of the article.

§ 2. Before undertaking a detailed review, a few general observations might be made. In the first place, it must be remarked that for the author to call his theory a new relativity is to give a completely false impression of his own work. If anything at all, the main thesis of the work is purely anti-relativistic and is vehemently opposed to a principle of relativity in any form whatsoever. Further one is struck by the large preponderance of books on popular expositions of relativity in the references to literature given at the end of the articles and this perhaps gives a clue to the great aversion to relativity which is manifest in the author's work. For, as is well known, the champions of the Theory of Relativity too often delight to bring forward those results of the theory which appear to them to be specially fitted to shock the common sense of people who take statements too literally and relativity is not the only example of a physical theory which appears absurd when its logical consequences are pushed to their very limit. In the list of references placed at the end of the second article it is curious to find the book "*Mysterious Universe*" ascribed to Eddington.

There are some mis-statements of facts in the author's references to relativity the most serious of which are in connection with the observational verifications of the general Theory of Relativity. The author says, (p. 4, Ch. 1), "It is now established that the supposed verifications are not exact," but the references to literature in support of this statement do not refer to the best observational data which are universally accepted. For the advance in the longitude of perihelion of Mercury the observational value is given as 40″·00 per century (the reference being to Eddington's *Mathematical Theory of Relativity*) whereas the best determinations are due to Chazy[4] and give 43″·5 as against the

[1] *Science*, 1934, **80**, 439.

[2] *Science*, 1935, **81**, 271–272.

[3] *Zentrablatt für Math.*, 1935, **10**, 88.

[4] *Comptes Rendus*, 1926, **182**, 1134.

theoretically predicted 42″·9. In the case of the gravitational deflection of light the author refers on p. 25, Ch. 1, to values obtained at several eclipse expeditions but significantly omits to mention the most satisfactory data available at present, *viz.*, those of Campbell and Trumpler,[5] who obtained the results 1″·72±0″·11 and 1″·82±0″·15 with two different sizes of cameras in the 1922 expedition of the Lick Observatory. As regards the gravitational shift of spectral lines a reference is made to the older work of St. John as quoted in Eddington's *Math. Theory* whereas in the cases of *both* the Sun and the dense companion to Sirius the agreement between the Theory of Relativity and observation is quite satisfactory as a result of the later work of St. John[6] and of Adams.[7] It appears therefore that the claims of Sulaiman's theory that it gives results more in accordance with observation than relativity are to be taken with some reservation. Other mis-statements of a minor nature are that relativistic invariance holds in vacuum only (p. 3, Ch. 1), that Einstein arbitrarily assumes $c+v=c$ and $c-v=c$ (p. 32, Ch. 2), that Milne's theory *ignores* gravitation and *evades* collisions (p. 224, Ch. 3) and that, in relativity, time is *wholly imaginary* and space *illusory* (p. 253, Ch. 5).

The mathematical part of the work is quite elementary and does not go beyond the solution of an ordinary differential equation of the second order. Looking from an æsthetic-mathematical point of view, one searches here in vain for such concepts like groups, tensors and generalised spaces characteristic of relativity or functional equations, sets of points, and Finsler spaces relevant to Milne's new relativity. On the other hand we have a set of drab differential equations as a series of approximations ninety per cent. of which is not relevant even to the author's own work. In dealing with the relativistic equation of a planetary orbit the exact solution of which can, as is well known, be expressed in terms of elliptic functions, the author claims to have devised a method superior to the methods of Forsyth, Morley and Pierpoint (p. 14, Ch. 1). A little scrutiny however shows that this superiority of method is achieved at the cost of a little wrong mathematics (*see* Section 9, p. 14, Ch. 1).

To obtain a solution of

$$\frac{d^2u}{d\theta^2}+u-\frac{3\mu}{D^2}u^2=\frac{\mu}{h^2}(1-2k\theta) \quad .. \quad (2.1)$$

the author considers the solution of

$$\frac{d^2u}{d\theta^2}+u-\frac{3\mu}{D^2}u^2=0 \quad .. \quad .. \quad (2.2)$$

which is correctly obtained as

$$u=\frac{D^2}{6\mu}+\wp\left\{\frac{\sqrt{\mu}}{D\sqrt{2}}(\beta-\theta)\right\}.$$

It is then stated that the solution of (2.1) is given by

$$u=\frac{\mu}{h^2}(1-2k\theta)+\frac{D^2}{6\mu}+\wp\left\{\frac{\sqrt{\mu}}{D\sqrt{2}}(\beta-\theta)\right\} \quad .. \quad (2.3)$$

presumably on the strength of the theorem that the general solution is the sum of the complementary function and a particular integral. It is, however, absurd to use this theorem here since it cannot apply to nonlinear differential equations like (2.1) and, moreover, $\mu(1-2k\theta)/h^2$ is not a particular integral.

As examples of the author's attitude towards scientific investigation we might mention his views (1) that Nature's limits are not fixed by our capacity to observe them (p. 230, Ch. 4), (2) that relative velocity cannot mean relative velocity as actually observed and we cannot go by measurements only (p. 242, Ch. 5), and (3) that a certain concept in relativity is unacceptable because the concept is philosophically an impossible one (p. 226, Ch. 3).

Finally on a point relating to a question of priority, it is highly amusing to see the author refer to a paper by P. Jordan mentioning gravitational quanta and claim priority by pointing out that his own theory was published in 1933 and again in 1934. It might be pointed out that, if it be a question of the "gravitons" of the Sulaiman type subject to the impulsive pulls and pushes of Newtonian dynamics, a whole literature[8] about them already exists. These "gravitons" have in fact a very close family resemblance to the "corpuscules ultramondains" of Le Sage,[9] the "radiating

atomules" of O. Keller,[10] and the "residual attraction" of Crehore.[11] If, on the other hand, it be a question of gravitational quanta the possibility of whose existence is a consequence of the complementarity of the wave and corpuscular aspects of modern quantum mechanics, it is needless to say that such a concept is now quite well known for a number of years and finds a place even in elementary books on wave mechanics.[12]

§ 3. GENERAL RELATIVITY. (*a*) *Advance of Perihelion.*—The two main ideas which the author uses for dealing with gravitational phenomena are the finiteness of the velocity of propagation of gravitation and the introduction of a correction to Newton's law for the case of moving bodies. Both these ideas have no novelty in them going back in fact to the work of Laplace[13] and a series of later investigators.[14] Laplace himself did not assume any variations of Newton's law for moving bodies but only the finiteness of the velocity of propagation. He was thus led to apply a sort of an *aberration principle*, but his results were completely against all observed values in planetary perturbations. Assuming D the velocity of propagation of gravitation equal to c the velocity of light, his theory did not correctly give the advance of Mercury's perihelion and, in addition, gave a secular variation of the mean longitude contrary to observation. An attempt to bring down this secular variation to the observed value necessitated the assumption that $D=500\,c$. It was later shown by Lehmann-Filhès[15] that such an attempt in the case of the perturbation of the moon's longitude required the assumption for D a value nearly a million times c.

Coming now to theories which assume both the finiteness of D and a modification of Newton's law we have the theories of Weber, Riemann, Gauss, Neumann, Clausius, Anding and Gerber. On the unsatisfactory nature of the first five theories reference may be made to the sources[16] mentioned above and we might confine our attention to the last two, specially to Gerber's theory which bears a great resemblance to Sulaiman's work. Anding[17] substituted for the Keplerian equations of motion the following equations

$$\frac{d^2x}{dt^2}+\frac{\mu x}{r^3}=\frac{\mu}{c}\cdot\frac{x}{r^3}\cdot\frac{dr}{dt};$$
$$\frac{d^2y}{dt^2}+\frac{\mu y}{r^3}=\frac{\mu}{c}\cdot\frac{y}{r^3}\cdot\frac{dr}{dt}$$

in order to explain the perihelion advance of Mercury, but these give rise, in addition, to a large perturbation in the eccentricity which is quite contrary to observation. Gerber[18] started with an expression for the potential in the form

$$P=k^2m_1m_2:r\left[1-\frac{1}{D}\frac{dr}{dt}\right]^{\alpha}$$

and determined the constant α in order that the perihelion advance thus given may equal the observational value which he took $41''.25$ per century (with $D=c$). He thus obtained two possible values of α, *viz.*, $\alpha_1=2$ and $\alpha_2=-3$ and assumed the former value for his correction to Newton's law. It is remarkable that the other value $\alpha_2=-3$ gives Sulaiman's law if we observe that it is derivable from the above potential, remembering that Sulaiman's correction factor does not depend on r. The criticisms levelled against Gerber's theory therefore apply to Sulaiman's theory equally well and reference in this connection might be made to the remarks of Seeliger,[19] Laue[20] and Oppenheim.[21] Any one who has worked in the perturbation theory of celestial mechanics knows quite well that modifications of the Newtonian law introduced to explain a certain anomaly give rise to unforeseen perturbations in other elements of the planetary orbit. This is exactly what happens with Gerber's theory which, like the theory of Anding, gives unwanted perturbations in the eccentricity or alternatively an assumption that D is nearly 10^4c. We should therefore expect similar absurdities to arise in Sulaiman's theory and this has been confirmed by Hamilton who has shown that this theory gives an yearly increase of eccentricity equal to $0\cdot0026$

[21] *Ann. d. Phys.*, **53,** 163.

which means that Mercury goes off in a parabolic orbit within about three centuries! Alternatively an attempt to bring down this perturbation in eccentricity to Newcomb's value of $(-4 \cdot 3 \pm 2 \cdot 5 \times 10^{-8})$ per year requires the assumption $D = 6 \times 10^4 c$!

It would not be out of place to mention here other theories relating to the advance of Mercury's perihelion. We have Asaph Hall's[22] alteration of the law of Newtonian attraction from r^{-2} to $r^{-(2+\delta)}$ which gives the required perihelion advance if δ be put equal to $0 \cdot 00000016$ but, apart from its arbitrary nature, it gives a movement of 135″ in the apse of the Moon which is negatived by observation. Again the assumption of the oblateness of the Sun[23] explains the perihelion advance but gives very large perturbations of the inclination of Mercury's orbit. Finally the zodiacal theory of light[24] also gives rise to unwanted perturbations. One is therefore led, almost by a process of exhaustion, to Einstein's theory which by its very nature does not give any perturbations.

(*b*) *Gravitational Deflection of Light.*—The author's derivation for the deflection of light of a value equal to 4/3 times the Einstein value can only be described as truly amazing! He states (Ch. 1, p. 4) that Gerber's equation does not yield the value for the deflection which is certainly true and the same should also be true of Sulaiman's equations if properly handled. His method consists in taking the equation

$$\frac{d^2u}{d\theta^2} + u = \frac{\mu}{h^2} + \frac{3\mu}{D^2} u^2 \ (D = c) \quad .. (3 \cdot 1)$$

as the differential equation of the path of a light particle in a gravitational field. This equation is the relativity equation for the path of a material particle and in Sulaiman's theory it is only an approximate equation (*viz.*, the third approximation) there being approximations of four higher orders. The general equations of Sulaiman's theory are obtained by treating v (velocity of the particle) as small compared with D and consequently neglecting higher powers of $\left(\frac{1}{D}\frac{rd\theta}{dt}\right)$ than the first. It is therefore obvious that when one is dealing with the motion of a particle whose velocity is D itself (*i.e.*, a light particle, since D is taken equal to c), it is wrong to start with an approximate equation. The author himself sees the need of this when he is dealing with the motion of an electron in connection with his explanation of the fine structure of spectral lines (Ch. 5, p. 258). The straightforward thing to do in this case is to write down the equations of motion *ab initio* using the relation $v = D$ and when this is done with the equations in Sec. 5, Ch. 1, p. 9, we easily obtain the equation to the path of the light particle

$$\frac{d^2u}{d\theta^2} + u = 0 \quad .. \qquad .. \qquad .. (3 \cdot 2)$$

that is, a straight line showing that there is no deflection for a light particle in a gravitational field! This could also be *qualitatively* verified from Sulaiman's law of attraction, *viz.*,

$$-\frac{\mu}{r^2}(1 - v/D)^3 \text{ by putting } v = D$$

and is in consonance with what Gerber's equations can give for the deflection. Thus while on the old pure Newtonian theory we could deduce a deflection at least equal to half the Einstein value, this generalisation by Sulaiman yields no deflection at all!

Assuming for a moment that (3.1) correctly gives the path of a light particle, the author still fails to justify his final result, for when he states (Ch. 2, p. 25) that $r\frac{d\theta}{dt}$ can never exceed the *tangential velocity c*, he assumes unconsciously that the tangential velocity is constant, but this cannot certainly be true. Even in the derivation of the deflection on Newtonian mechanics c is assumed to be the velocity at infinity of the light particle. The assumption of a constant tangential velocity is equivalent to taking the central orbit as circular and it becomes meaningless to talk of the deflection as the angle between the asymptotes of the orbit. Such circular orbits[25] are also possible for light particles according to general relativity but they are excluded[26] for purposes of obtaining the deflection.

There is a third mistake in this derivation of the deflection. By showing that the least value of the expression on the right hand side of (3.1) is $\frac{4\mu}{D^2}u^2$ $(D = c)$ the conclusion

---

is drawn that the deflection *is* exactly 4/3 times the Einstein value, but the correct conclusion to draw is that it *is at least* 4/3 that value. In a case like this where observational verification is essential one would naturally enquire what would be the *maximum* deflection possible, but the work is silent on this point!

(c) *Shift of Spectral Lines.*—No remarks appear to be necessary in this case for, according to the author's own showing, the "corrections provided by the 'New Relativity' are not appreciably large and the value of the ratio is the same as Einstein's" for spectral lines in the solar spectrum. For planetary spectra he remarks, "Unfortunately the ratios for the planets are too small as compared to that of the Sun and the more accurate formulæ cannot give any better results at present."

Having examined the achievements of this 'New Relativity' in the three crucial tests, we can well conclude by saying that no one would seriously think of adopting it as an alternative to the general theory of relativity for the explanation of gravitational phenomena.

§ 4. SPECIAL RELATIVITY. (*a*) *Relative Velocity.*—The author enunciates his 'first universal principle' as follows (Ch.5, p. 247):

The relative velocity v between two bodies moving with velocities u and v′, measured by employing a messenger travelling with a velocity D in a to-and-fro journey, is given by the formula

$$\frac{v}{v'-u} = \frac{\mathrm{D}(\mathrm{D}+v'-u)}{(\mathrm{D}+v')\,(\mathrm{D}-u)} \quad .. \quad (4.1)$$

and claims that this formula is more general than the corresponding formula of special relativity

$$v = \frac{v'-u}{1-\dfrac{v'u}{c^2}} \quad .. \quad .. \quad .. \quad (4.2)$$

by showing that (4.2) is an approximation obtained from (4.1) by neglecting terms like $(v'^2u-v'u^2)/\mathrm{D}^3$, etc.

It is difficult to see how a correspondence could be established between (4.1) and (4.2) if it be noted that in the derivation of (4.1) the notions of absolute space and absolute time are retained while these are foreign to relativity. (4.1) applies even to the case where u and v' are velocities relative to an observer who is at rest in his own system, while in such a case both classical and relativistic kinematics give $v'-u$ for the relative velocity. As an example of confused thinking it is hard to find anywhere in relativistic literature a parallel to the author's derivation of equation (4.1). An absolute distance between two moving points is assumed as r independent of all measurement and on this are made to depend a real and an apparent distance. This leads on to the notions of absolutely real relative velocities, apparently real relative velocities and really apparent relative velocities! Let us however assume that (4.1) actually corresponds to the relativistic equation (4.2). We can then deduce some absurd consequences.

(i) Putting $v'=\mathrm{D}=c$ in (4.1) we deduce $v=c-u/2$ while classical kinematics gives $v=c-u$ and relativity gives $v=c$. We can therefore describe the Sulaiman kinematics as a sort of a hybrid form or as a sort of a semi-emission theory similar to the emission theory of Ritz.[27] Sulaiman's kinematics founders therefore on the rock of de Sitter's binary star test[28] as all other emission theories do.

(ii) Formula (4.1) looks superficially like a generalisation of Einstein's formula for addition of velocities and the author applies it to derive Fresnel's formula for the dragging coefficient and claims to have obtained a better approximation than the usual expression

$$c'_1 = c_1 - u\left(1-\frac{1}{\mu^2}\right) \quad .. \quad .. \quad (4.3)$$

where c'_1 is the velocity of light in moving water, $c_1=c/\mu$ the velocity in stationary water and u the velocity of the water. The corresponding expression deduced from (4.1) reads

$$c'_1 = \frac{\left(c_1-u\right)\left(1+\dfrac{c_1}{c}-\dfrac{u}{c}\right)}{\left(1+\dfrac{c_1}{c}\right)\left(1-\dfrac{u}{c}\right)} \quad .. \quad (4.4)$$

The actual reduction of (4.4) to an equation of the same form as (4.3) (which the author has not carried out) gives after a slight simplification

$$c'_1 = c_1 - u\left[1-\frac{1}{\mu(\mu+1)}\right] \quad .. \quad (4.5)$$

In the case of water (4.3) gives for the second term on its right hand side the value of $0{\cdot}44\,u$ which has been well confirmed by the

---

[27] *Ann. de. Chim. et Phys.*, 1908, **13**, 145.

[28] *Proc. Amsterdam Acad.*, 1913, **15**, 1297 and 1913, **16**, 395.

experiments of Fizeau[29] and the later very accurate researches of Zeeman.[30] On the other hand formula (4.5) gives in the same case the absurdly high value of $0\cdot 68\,u$ which is contrary to all observational results.

We can therefore safely dismiss as idle speculation all the results derived on the basis of this 'universal principle' and in particular the ridiculous analogues to Lorentz transformations on pp. 247-48, Ch. 5, between two moving systems which have a common time $t=t'$!

(*b*) *The Principle of Aberration* (Ch. 5, p. 251).—This principle which follows as a consequence of the finiteness of the velocity of propagation of a force has been mentioned already in connection with Laplace's theory of gravitation and is made extensive use of by the author who takes it as his second universal principle. According to him it is merely the necessary result of the compounding of two dynamical velocities, but it is difficult to see any justification for the reduction in the intensity of force along its apparent direction. It really makes no sense to say that when the velocity of flow is D, the effective *component of force* observed along the apparent direction *is D cos α*. There is an utter confusion here between velocity and force. This confusion is also responsible for the meaningless phrase "*the velocity of light* ON *a body moving with velocity v*". The claim of universality of application of this principle is belied by assuming that in the case of light the velocity is reduced while in other cases the intensity of force is changed (for example H in the explanation of Bucherer's experiment). There is yet another inconsistency in the application of this aberration principle to the case of "gravitons". The universality claimed would certainly require the modification in Newton's law of attraction to be $-\frac{\mu}{r^2}:\left(1+\frac{v^2}{D^2}\right)^{\frac{1}{2}}$ leading on to Gerber's equations, but the author uses, instead, the factor $\left(1-\frac{v}{D}\right)^3$ deduced from special consideration of 'graviton' pulls.

In his explanation of Minkowski's equation and of the possibility of velocities exceeding that of light the equations made use of are

$$\left.\begin{aligned} c_1 &= c\cos\alpha \\ \tan\alpha &= v/c \end{aligned}\right\} \qquad \ldots \qquad \ldots (4\cdot 6)$$

where c_1 the apparent velocity of light has its direction perpendicular to that of v and α is the angle of aberration. If, as the author states, the principle of aberration is merely the result of compounding dynamical velocities it is impossible to see how both the equations in (4.6) could be simultaneously true. It is on the basis of such 'flawless' mathematics that the possibility of velocities up to ∞ is deduced and one might well suggest to the author the derivation of his first universal principle when one of the bodies is moving with such a velocity, for example a velocity greater than that of the messenger employed.

(*c*) *Michelson and Morley Experiment.*—The explanation offered is briefly as follows:—

Time of longitudinal journey

$$= \frac{l}{c+v} + \frac{l}{c-v}$$

$$= \frac{2lc}{c^2-v^2} \qquad \ldots \qquad \ldots \qquad \ldots (4\cdot 7)$$

Time of transverse journey

$$= \frac{2l}{\sqrt{c_1^{\,2}-v^2}} \qquad \ldots \qquad \ldots \qquad \ldots (4\cdot 8)$$

where c_1 is the same quantity as in (4.6).

Hence the difference in times

$$= \frac{2lc}{c^2-v^2} - \frac{2l}{\sqrt{c_1^{\,2}-v^2}}$$

$$= \frac{2lc}{c^2-v^2} - \frac{2l}{\sqrt{c^2-2v^2}} \text{ using } (4\cdot 6)$$

$$= -\frac{l}{c}\left(\frac{v}{c}\right)^4 \text{ nearly,}$$

which cannot be detected by experiment.

By using the author's own 'universal principles' it can easily be shown that this explanation is untenable. For, according to the first universal principle of relative velocities, (4.7) should be replaced by

$$\frac{l}{c-v/2} + \frac{l}{c+v/2} = \frac{2lc}{c^2-v^2/4} \qquad \ldots (4\cdot 9)$$

Again (4.8) is obtained by a wrong application of the second universal principle according to which the effect of a finite velocity of flow is the same *as if the body were stationary* and the direction of flow were shifted forward by an angle α and the velocity changed from c to c_1. It is therefore wrong to again compound c_1 with v and hence (4.8) should be replaced by

$$\frac{2l}{c_1} = \frac{2l}{\sqrt{c^2-v^2}} \qquad \ldots \qquad \ldots (4\cdot 10)$$

Hence the difference in times

$$= \frac{2lc}{c^2-v^2/4} - \frac{2l}{\sqrt{c^2-v^2}} = -\frac{l}{c}\cdot\frac{v^2}{2c^2}$$

[29] *Comptes Rendus*, **1851**, **33**, 349.

[30] *Amsterdam Proceedings*, 1914, **23**, 245; 1915, **24**, 18.

which can certainly be measured but is contradicted by the null result of the Michelson-Morley experiment.

(*d*) *Fine Structure of Spectral Lines.*—The author has not derived the formula for fine structure on the basis of his own theory but only talked about in a certain hazy way which tends to suggest that he is unaware of the methods of even the old Bohr-quantum theory. One would naturally start with the proper expression for the Hamiltonian, then set up the Hamilton-Jacobi equation and introduce the angle and action variables, the quantum conditions being derived by equating the non-degenerate action variables to integral multiples of Planck's constant. Nothing of the sort is done here and it is suggested that the same equations of Newtonian form as used for planetary orbits should be employed with the retention of the term $\left(\frac{1}{D}\,\frac{rd\theta}{dt}\right)^2$ and the reader is left to proceed as best as he can with the help of the third universal principle which deals with the force acting on a spinning spherical shell. It is really a complete mystery what this universal principle has got to do with the motion of an electron in a central field of force and where this spinning spherical shell comes into the picture. In the absence of any quantitative results, it is impossible to attach any weight to the author's explanations.

§ 5. COSMOLOGY. We may well spare the author the joy of his profound cosmological speculations and trenchant criticism of other cosmological theories and proceed to examine those positive results of his theory which are expressed in a mathematical form. The only such result is the derivation of Hubble's famous velocity-distance law on the basis of the author's emission theory of matter and the conclusion therefrom that not only velocities of recession of nebulæ but also velocities of approach are possible. The fundamental equation is

$$\frac{d^2R}{dt^2} = \gamma\frac{dR}{dt} \quad \ldots \quad \ldots \quad \ldots \quad (5\cdot1)$$

where R may be measured in any direction and from any origin and $\gamma = \frac{n\mu}{3}$, n being the number of gravitons emitted from unit mass per unit time and μ the mass of each graviton. From (5.1) we obtain by integration

$$\frac{dR}{dt} = \gamma R + A_0 \quad \ldots \quad \ldots \quad (5\cdot2)$$

which is the expression for the velocity-distance law. From (5.1) also follows a cosmological principle that the relation of acceleration and velocity presents the same picture to all observers. It might be observed, in passing, that this cosmological principle can be considered as a particular form of Milne's principle of equivalent observers. On the basis of (5.2) it is claimed that velocities of recession and approach are both possible.

It might be remarked in the first place that the deep-lying velocity-distance proportionality could be very simply deduced[31] from pure classical *kinematic* considerations only on the basis of a cosmological principle of equivalent observers of the type derived by the author himself. Even in relativistic cosmology it is a simple deduction[32] from the form of the metric assumed in non-static models of the Universe. It appears therefore that it is quite redundant for the purposes of deriving Hubble's law to invoke the aid of an emission theory of matter which calls to aid supernatural agencies for the production of gravitons by the explosion of a sub-atomic shell.

It is again wrong to say that (5.2) explains both recession and approach. For, since R can be measured in any direction and from any origin, a simple change or origin reduces (5.2) to the equivalent form

$$\frac{dR}{dt} = \gamma R \quad \ldots \quad \ldots \quad \ldots \quad (5\cdot3)$$

and γ, by its very definition, is a *positive* quantity unless one were to indulge in Schuster's[33] "holiday dreams" of negative masses. Thus (5.3) shows that $\frac{dR}{dt}$ has always the same sign as R, *i.e.*, the velocity is one of recession. All the enchanting speculation about approaching and receding nebulæ and a stable Universe are therefore seen to be without a foundation. Finally the author's criticism of relativistic cosmology loses much of its force if it be observed that he confines himself to the de Sitter static model whereas the trend of modern work[34] is in the direction of considering non-static models as better suited to explain observed facts.

The Particle Problem in the General Theory of Relativity.

IN a recent paper published in the *Physical Review* (Vol. **48**, 73), A. Einstein and N. Rosen have called attention to a possibility of accounting for atomic phenomena by the method of general relativity. Their essential idea consists in removing the singularities of the solutions of the field equations by a simple modification.

One will then have to treat physical space as consisting of two congruent sheets, the particle (neutral or electrical) being interpreted as a portion of space connecting the two sheets, *i.e.*, as a kind of bridge. The determinant of the components of the metric tensor vanishes at the surface of contact of the two sheets. Next, they recognise in the postulate of relativity which states that the motion of a particle takes place along a geodesic, a defect that the field and motion have been separated out. Einstein and Rosen regard that the concepts of particle and motion have to be treated as a part of the field itself. If there are several particles present, one should find a solution free from singularities of the space consisting of two sheets connected by many bridges if he adopts the above point of view. However, one cannot say whether regular solutions with more than one bridge exist at all.

The new field equations adopted by Einstein and Rosen are

$$g^2 R_{kl} = 0$$

instead of the old equations. This adoption would remove the singularities caused in the field equations by the vanishing of the g factors in the denominators of R_{kl}. The regular solution for the spherically symmetric static case is now

$$ds^2 = -4(u^2+2m)du^2 - (u^2+2m)^2(d\theta^2+\sin^2\theta d\phi^2) + \frac{u^2}{u^2+2m}dt^2$$

$$u^2 = r - 2m$$

instead of the Schwarzschild solution,

$$ds^2 = -\frac{1}{1-2m/r}dr^2 - r^2(d\theta^2+\sin^2\theta d\phi^2) + (1-2m/r)dt^2$$

which has a singularity for g_{11} when $r=2m$. In the new solution g vanishes when $u=0$, as g_{44} vanishes. The space can now be regarded as made up of two equivalent sheets corresponding to $u>0$ and $u<0$ joined by a plane $u=0$ or $r=2m$. Einstein and Rosen conceive of a bridge-like connection between the two sheets. They interpret it as a mathematical representation of an elementary, electrically neutral particle. This representation accounts for the non-existence of an elementary particle with negative mass, for one cannot regularise the Schwarzschild solution if it is so.

Just as in the above case of pure gravitational field, Einstein and Rosen have modified the field equations when both gravitation and electricity are present by multiplying the field equations by the factor g^2 and changing the sign of T_{ik}. They find the regular solution for a static spherically symmetric case with an electrostatic field as

$$ds^2 = -du^2 - (u^2+\epsilon^2/2)(d\theta^2+\sin^2\theta d\phi^2) + [2u^2/(2u^2+\epsilon^2)]dt^2$$

$$u^2 = r^2 - \epsilon^2/2$$

taking $m=0$. Einstein and Rosen believe that the massless solutions are the physically important ones to interpret an elementary electrical particle. One can see that the above solution is free from singularities and that the space is divided into two congruent sheets and that the charge is represented by a bridge between the two sheets. According to this, the most elementary electrical particle has no gravitating mass.

In the conclusion, they say, "Nevertheless one should not exclude *a priori* the possibility that the theory may contain the quantum phenomena. Thus it might turn out that only such regular many-bridge solutions can exist for which the 'charges' of the electrical bridges are numerically equal to one another and only two different 'masses' occur for the mass bridges, and for which the stationary 'motions' are subject to restrictions like those which we encounter in the quantum theory. In any case here is a possibility for a general relativistic theory of matter which is logically completely satisfying and which contains no new hypothetical elements."

Diamagnetism of the Trivalent Bismuth Ion.

THE diamagnetic susceptibilities of a number of ions have been calculated by Pauling,[1] Stoner,[2] Slater[3] and Angus.[4] These theoretical considerations have enhanced the interest in the experimental determinations of ionic susceptibilities.

We have determined the diamagnetic susceptibilities of a number of trivalent bismuth salts by the aid of the Bhatnagar-Mathur Magnetic Interference Balance.[5] The value for χ_A for Bi^{+3} has been calculated by subtracting the value of the susceptibility of the negative ion from the experimentally determined value of the molecular susceptibilities of the salts.

Most of the values of χ_A for the negative ions have been taken from Kido's careful investigations.[6] For Cl′, the value 19·8 as experimentally determined in this laboratory[7] has been used. The χ values for $(PO_4)'''$, O″, and S″ have been taken from the International Critical Tables; the value of $(CrO_4)''$ has been calculated from that of H_2CrO_4 and the value for the citrate ion has been calculated from the values of χ for carbon, hydrogen and oxygen atoms as given in the International Critical Tables.

The results obtained are shown in the table below.

Salt	$-\chi_a \times 10^6$	$-\chi_m \times 10^6$	$-\chi_A \times 10^6$ for Bi^{+3}
Bismuth oxide Bi_2O_3	0·170	79·22	42·20
Bismuth hydroxide $Bi(OH)_3$ ..	0·253	65·78	40·28
Bismuth trichloride $BiCl_3$	0·316	99·65	40·10
Bismuth tribromide $BiBr_3$	0·328	146·94	42·84
Bismuth triiodide BiI_3	0·340	200·53	40·93
Bismuth sulphide Bi_2S_3	0·240	123·40	38·45
Bismuth phosphate $BiPO_4$	0·254	77·22	41·72
Bismuth sulphate $Bi_2(SO_4)_3$ ..	0·282	199·14	41·07
Bismuth chromate $Bi_2(CrO_4)_3$ ..	—0·202	—154·33	43·45
Bismuth citrate $BiC_6H_5O_7$ ..	0·302	120·20	41·38

The value of χ for Bi^{+5} has been calculated by Angus. The value for Bi^{+3} which is the commonest bismuth ion does not seem to have been calculated by either the Slater or the Angus method. In view of the experimental data available, we have calculated

the theoretical value of χ for Bi^{+3} by the Slater method, as a comparison of the theoretical and the experimental values should be of considerable interest.

The gram atomic susceptibility χ_A is given by the expression :

$$\chi_A = -\frac{e^2 L}{6mc^2} \Sigma_N r^{-2} \quad \ldots \quad \ldots \quad \ldots \quad (1)$$

According to Slater, the values of r^{-2} are given by

$$r^{-2} = \frac{(n')^2(n'+\frac{1}{2})(n'+1)}{(z-s)^2} \quad \ldots \quad \ldots \quad (2)$$

The values of χ_A can therefore be obtained according to equation (1) by summing over all the electrons remembering that r^{-2} in (2) is given as a multiple of a_0^2 where a_0 is the radius of the innermost orbit in hydrogen ($a_0 = \cdot528 \times 10^{-8}$). This gives

$$-\chi_A \times 10^6 = 0 \cdot 790 \ \Sigma \frac{(n'^2)(n'+\frac{1}{2})(n'+1)}{(z-s)^2} \quad (3)$$

Calculating the values of r^{-2} for different electronic groups in Bi^{+3} and summing up, the value of Σr^{-2} is found to be 55·448. Substituting this value in (3) the atomic diamagnetic susceptibility of Bi^{+3} comes to be $43 \cdot 8 \times 10^{-6}$.

The value of χ_A for Bi^{+3} has been experimentally found to be 41·24 and is in close agreement with the theoretical value 43·8 calculated according to Slater's method. Angus has introduced a slight modification in Slater's formula for evaluating the effective nuclear charge. This modification has the effect of lowering the calculated value for susceptibility and would bring it in closer agreement with the experimental value.

The Emission of Fast Particles.

As a result of a series of experiments recently carried out by Rutherford and others,[1,2] it has been shown that from a number of radioactive elements groups of fast particles are often emitted. Moreover the elements which are supposed to emit particles of given velocity really give out particles of velocities varying over a small range. Accordingly the wavestatistical formula deduced before[3] must be modified.

From a numerical computation of the energy of the disintegrated α-particles, it can be shown that they become free at least at a distance $10^{-13} \rightarrow 10^{-12}$ cm., from the centre of the core. On the other hand the wavestatistical formula of the radius of the hard core gives $r_0 \sim 10^{-15}$ cm., for radioactive substances. So we have to suppose that the region between 10^{-15} and 10^{-13} cm. is filled with electrically neutral particles. Evidently it corresponds to the neutral shell of Rutherford. Since it is outside the charged core, the electrical force of repulsion is Coulombian in this region.

According to Rutherford the shell is filled with polarised helium atoms. But it appears a more general assumption would be to suppose that the shell is packed with large numbers of α- and β-particles, such that the net charge is zero. The particles may possibly circulate in a number of orbits under a polarisation field. Thus the neutral shell may be supposed to consist of a number of thin shells of particles. Now as soon as an α-particle comes out of the core and passes through the shell, it will naturally interact with the circulating α-particles in the thin shells. And as a result of that an α-particle which was originally present in the shell is ejected.

It is evident that the rate of disintegration is really the rate of ejection from the thin shells. The previous wavestatistical formula gives the rate at which the α-particles enter the shell from the hard core within. Multiplying this rate by the number of α-particles present in an excited state in a given thin shell, we find for the disintegration constant:

$$\lambda = \text{const.} \frac{\sqrt{U_0 E}}{\text{Cot} u_0} \cdot e^{-2k(2u_0 - \sin 2u_0)} \sin^2 \frac{2\pi m v r_1}{h}$$

where the symbols have been explained in the previous paper.[4,5]

If it is supposed that the α-particles belonging to a particular group are all emitted with the mean velocity, then the factor $\sin^2 \frac{2\pi m v_1}{r_1}$ becomes evidently unity,

and the above reduces to the older wave-statistical formula.

Rolf's Graphs to Sommerfeld's Attenuation Formula.

NORTON[1] has recently pointed out an error in Rolf's[2] calculations of flat-ground attenuation of wireless waves according to Sommerfeld's theory.[3] Since Rolf's graphs have been extensively employed in connection with experimental investigations on ground-attenuation, it is necessary to test how far this error would vitiate the attenuation curves drawn by Rolf.

Setting right the error, Norton has given the following empirical formula for the attenuation factor S for small values of b:

$$S = f(p_0) - \sin b \, \frac{\sqrt{p_0}}{2} \, e^{-\frac{5}{8}p_0}$$

where p_0 is Sommerfeld's "numerical distance" and is equal to $q/2$ of Rolf. The quantities b and q are defined by

$$\tan b = \frac{\epsilon + 1}{6\lambda\sigma} \cdot 10^{-15} \text{ and } q = \frac{2\pi \sin b}{(\epsilon+1)\lambda} \cdot r$$

where σ (expressed in e.m.u.) is the electrical conductivity, ϵ (expressed in e.s.u.) the dielectric constant of the ground, λ the wavelength (in km.) and r the actual distance in km. from the transmitter. The first term $f(p_0)$ in Norton's expression for the attenuation factor can be calculated from Van der Pol's empirical formula:

$$S = f(p_0) = \frac{2 + \cdot 3p_0}{2 + p_0 + \cdot 6p_0^2}$$

(This formula is free from the error pointed out by Norton.)

In Table I we have compared the values of attenuation factor for different values of q obtained from Rolf for (1) $b = 5°$ and (2) $b = 0°$ with those calculated from Norton's formula. The values of attenuation according to Van der Pol are also given in the table.

TABLE I.

b	q	Attenuation Factor		
		Rolf	Pol	Norton
5°	3·0	·59	·50	·47
	2·0	·70	·64	·61
	1·0	·85	·81	·78
	0·2	·97	·95	·93
0°	3·1	·5	·49	·49
	2·3	·6	·62	·62
	1·7	·7	·69	·69
	1·0	·8	·81	·81
	0·4	·9	·92	·92

Rolf's values for $b = 5°$ are slightly higher than those calculated from Pol and Norton. There is better agreement when the values of q are very small. The agreement is perfect for $b = 0$. It should be remembered that Van der Pol's formula is valid only when $\sigma > \frac{2\pi c \epsilon}{\lambda}$. A little calculation will show that for this condition to hold, b should be less than 5°. It is therefore expected that for b greater than 5°, the values of attenuation calculated according to Pol will be discrepant.

We can therefore say that so far as we can test Rolf's attenuation curves *within the range of validity of the empirical formulæ*, the error pointed out by Norton does not appear to materially alter these curves at least for very short distances from the transmitter.

Whether the peculiar features in Rolf's graphs, *viz.*, the negative attenuation and the 'dips', exist according to Sommerfeld's theory cannot, however, be ascertained from Norton's formula. Fresh mathematical investigation is necessary to test these points.

Influence of Magnetic Field on the Coefficient of Viscosity of Liquids.

In view of the fact that Raha and Chattarjee[1] have recently published a paper on the influence of magnetic field on the coefficient of viscosity of liquids, it may be of interest to record an earlier attempt of mine, in 1932, in which a similar study was undertaken by a different method. The observed variation in the coefficient of viscosity due to the magnetic field being much less than 0·5 per cent., the results of the experiment were considered to be indecisive. The method employed and the results obtained were however included in my M.Sc. thesis, submitted in 1933 to the Mysore University, as an appendix, which runs as follows:

"*Viscosity measurements in a magnetic field.* In order to formulate a theory of viscosity of liquids and to derive an expression for its temperature coefficient Andrade[2] has made the assumption that the viscous force between layers in relative motion is due to transitory binding between molecules in the two layers. G. W. Stewart[3] has supported Andrade's view making use of the information derived from X-ray diffraction of liquids. His work has revealed the existence of constantly fluctuating 'liquid crystalline groups', which are due to molecular field in liquids. Hence the force between successive layers in relative motion is due to 'transitory and fluctuating crystallisation of liquid molecules'.

"Since molecules and molecular groups of several substances, especially those of aromatic compounds, have been found to possess magnetic anisotropy, they might be expected to experience a preferential orientation in a magnetic field, so far as thermal agitation allows them to do so. With a view to test if such an orientation affects the force between successive layers in relative motion and thus alter its coefficient of viscosity, measurements were carried on benzene by comparing the time of flow of the liquid through a constriction in a viscometer, when a magnetic field was acting at the constriction with that when it was not.

"The viscometer employed is shown in the figure and the constriction was a narrow capillary bent as shown in the figure. This was designed to suit the measurement in a magnetic field and was blown out of pyrex glass. The viscometer is so placed that the constriction lies in the narrow space between the poles of a Dubois magnet. In order that the tractive force might not affect the rate of flow of the liquid, care was taken to see that the bulb B was well above the pole pieces. The zig-zag path of the capillary keeps the liquid for a long time in the field. Liquid was sucked until the bulb B and the tube above it were filled with the liquid. When the liquid began to flow down the times taken by the liquid to travel from the mark *a* to *b* were noted both when the magnetising current was on and off, a number of times. The total time taken for the flow was 3 minutes and 15 seconds and in a few observations with the field on it came out as 3 minutes 14 seconds; but in other cases it was equal to the value in the absence of the field. It is inferred therefore that the magnetic field has no appreciable influence on the viscosity of a liquid. This might be due to a small fraction of the liquid molecules orienting themselves in the magnetic field. G. W. Stewart[4] has observed that appreciable orientation occurs in the milky state, very near the melting point (116° C.), in the case of para-azoxyasinol and that this orientation becomes almost negligible when the temperature of clearing (134° C.) is passed. An attempt will be made to conduct the above experiment having liquids at a few degrees above their melting points."

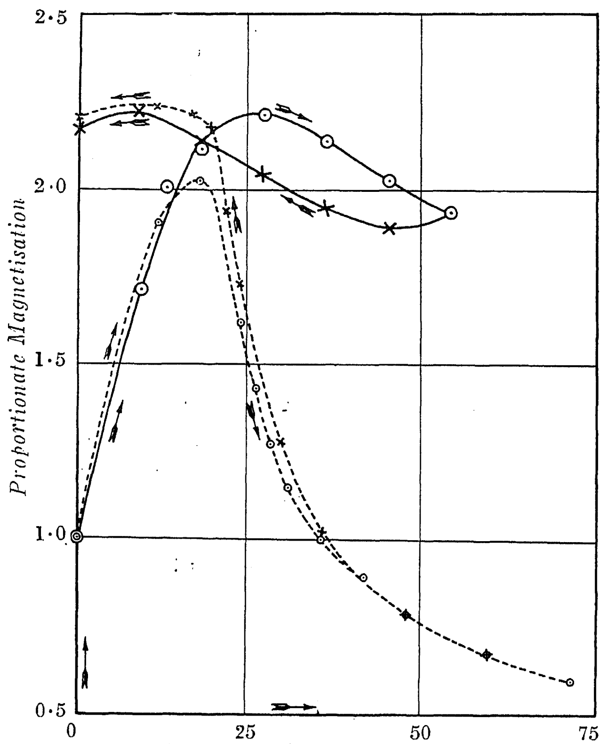
The Phenomenon of Negative Hysteresis in Nickel.

PROCOPIU[1] has studied the influence of an alternating circular or longitudinal field on the intensity of magnetisation of Iron and Steel in a constant magnetising field. The work has been extended to the case of Soft Iron and Nickel. The specimens in the form of wires were first put to a few complete magnetisation cycles in zero alternating field, and ultimately left in a weak magnetic field, so that the magnetisation had a small positive value. The alternating field was then gradually increased to a convenient value and then decreased subsequently. The longitudinal field was produced by passing an alternating current through a solenoid surrounding the specimen, and the circular alternating field, by passing an alternate current through the substance itself. The results for nickel are given in Fig. 1. The circular



— Circular Alternating Field (Constant Magnetic Field—19·30G).
---- Longitudinal Alternating Field (Constant Magnetic Field—19·54G).

alternating field refers to the field at the periphery of the wire and was calculated according to the formula $H = \frac{2I}{10r}$, where 'I' is the strength of the alternating current, and 'r' the radius of the specimen.

The result in the case of Soft Iron is essentially the same as Procopiu's, with the difference that a slight hysteresis is noticeable even in the descending part of the curve, which was absent in Procopiu's work. In the case of Nickel in alternating longitudinal field, the effect is similar in nature to that in the case of Iron, but in the alternating circular field, the behaviour of Nickel is anomalous. The curve for decreasing alternating field goes below that for the increasing field and a loop is formed between the two curves, thus showing Negative hysteresis.

A similar effect of Negative hysteresis has been noticed by several workers[2] in the Magneto-Resistance change of Nickel and has been ascribed by Stierstadt[3] to the previous magnetic treatment of the specimen, but its exact nature has not been understood as yet. It is significant that this Negative hysteresis appears only when a current passes through Nickel, as in the case of the alternating circular field and not in the case of the alternating longitudinal field, where no alternating current passes through the specimen. The occurrence of the effect in the Magneto-Resistance change, where again a current passes through the specimen, suggests that Negative hysteresis is connected with some aspect of the movement of conductivity electrons. The effect is no doubt real and an intensive study of the phenomenon is required for throwing light on this anomalous behaviour of Nickel.

The experiment was performed in the Physics Laboratory of the Patna Science College and my best thanks are due to the authorities for kind permission, specially to Prof. K. Prosad, I.E.S., for his constant interest in the work. I also wish to thank Dr. M. M. Sen Gupta, Senior Professor of Physics, Ravenshaw College, Cuttack, for helpful discussions.

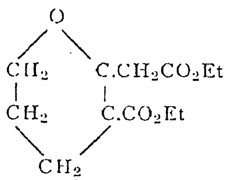
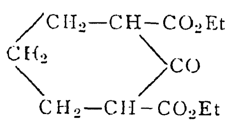
Action of Trimethylene Bromide on Acetonedicarboxylic Ester: A New and More Convenient Method of Synthesis of Ethyl *Cyclo*-hexane-2 : 6-Dicarboxylate.

PERKIN[1] obtained ethyl methyldehydrohexonedicarboxylate (I) by the action of trimethylene bromide upon Na-derivative of ethyl acetonedicarboxylate in alcoholic medium; the corresponding di-acid, m.p. 185°–92°, and the mono-acid mono-ester, m.p. 115°. The reaction was tried in dry benzene suspension by heating for nearly 100 hours at 140°–50° in sealed soda water bottles with the expectation that ethyl *cyclo*-hexanone-2 : 6-dicarboxylate, if formed under these conditions, would furnish a convenient starting material for the study of some 1 : 3-bridge formation in the *cyclo*hexane molecule. The reaction mixture was separated into two portions—petrol soluble and petrol insoluble. The former, about half of the whole in quantity, gave a liquid, b.p. 142°/2 mm. along with some unreacted ester and ethyl acetoacetate. The ester, b.p. 142°/2 mm. gave on hydrolysis a dibasic acid, m.p. 172°, and a mono-acid mono-ester, m.p. 83°, agreeing in composition with Perkin's compounds, which are isomeric with ethyl *cyclo*hexanone-2 : 6-dicarboxylate and its derivatives. From the petrol insoluble portion, the phenolic lactone, m.p. 188° [2] was isolated amongst other products not identified.



(I)



(II)

Having found the reaction of sodium or sodium ethoxide, upon acetone dicarboxylic ester is always attended with the formation of phenolic bodies and according to Perkin of compounds containing oxygen in the ring, it was considered desirable to try a milder metallic derivative. Trimethylene bromide reacts with the magnesium derivative of acetone dicarboxylic ester to yield the expected ethyl *cyclo*hexanone-2 : 6-dicarboxylate (II) b.p. 144°/3 mm.; phenyl hydrazone, m.p. 150°, mixed m.p. with a genuine sample remaining undepressed. This new method is more convenient to work with and the yield compares favourably with that obtained by the older method.

This new observation as also the formation of a suberone derivative[3] and of a *cyclo*-pentanone derivative[4] from Na-derivative of acetone dicarboxylic ester establish definitely that under suitable conditions it can react in the ketonic form lending itself to the formation of homocyclic compounds and not only in the enolic form as observed by Perkin.

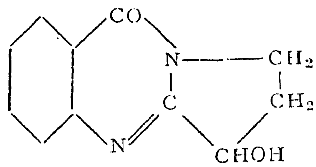
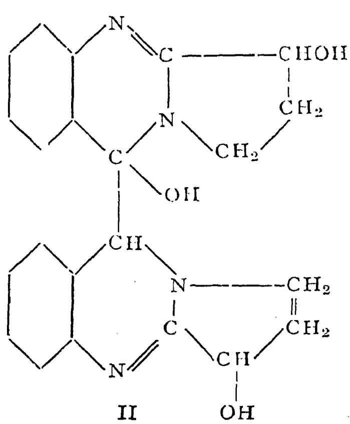
The Oxidation Products of Vasicine with Hydrogen Peroxide.

MORRIS, HANFORD AND ADAMS[1] have found that vasicine does not react with 3% H_2O_2 as stated by Ghose[2] *et al* but does so with 30% H_2O_2 and on interaction at 60°–70° it gives a compound m.p. 214° as stated by Ghose *et al.* To this compound, they have assigned the structure (I).



I

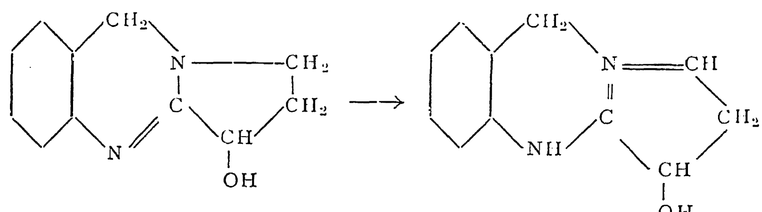
But a second product m.p. 168° obtained by Ghose *et al* was not found and they are of opinion that it was an equi-molecular mixture of I and vasicine.



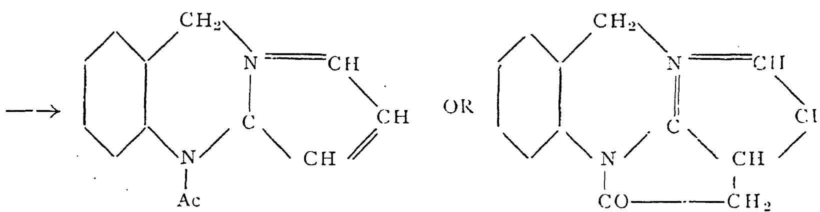
II

The strength of hydrogen peroxide stated by us to be 3% was a typographical error for 30%. Repeated experiments have invariably yielded the substance m.p. 168° and the constant analytical values obtained after crystallisation justify the view that it cannot be a mixture. Under the microscope the substance has a homogeneous appearance. Its formula was given by Ghose *et al* as $C_{11}H_{10}NO$; $\frac{1}{2}H_2O$. It is probably $2(C_{11}H_{10}NO; \frac{1}{2} H_2O)$, *i.e.*, $C_{22}H_{22}N_2O_3$ and its structure represented by II as it is almost quantitatively oxidised by H_2O_2 to I.

The acetyl derivative of vasicine was obtained as an oil by Spath, contrary to Ghose *et al* who record a m.p. 164°. It was this discrepancy which at one time suggested the possibility of vasicine being different from peganine. It is gratifying to note that Spath, Kuffner and Platzer[3] now find the m.p. to be 163–164°·5 in confirmation of Ghose *et al*. Its structure can be represented as below :

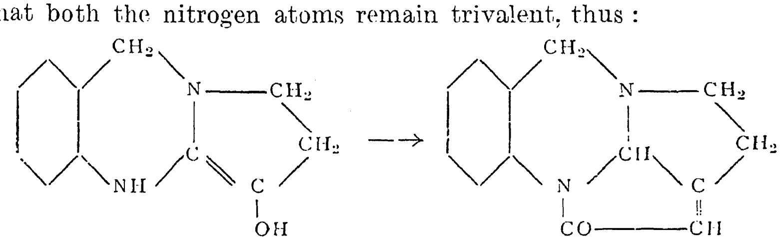


Vasicine Iso-Vasicine



It is more probable that both the nitrogen atoms remain trivalent, thus :

Vasicine →



Iso-Vasicine

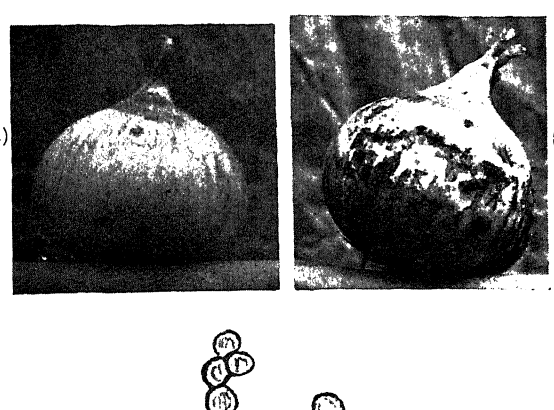
Storage-Rot of Onions.

IN 1932 the attention of the senior writer was attracted towards this serious disease, which caused a waste of more than half to his onion-store. Although exceedingly common, no mention about it is found in Butler's *Fungi and Disease in Plants* (1918), *The List of Specimens in the Mycological Herbarium, Pusa* (1921), *The Fungi of India, Calcutta* (1931), *The Fungi of Bombay* (1935). The causal agent, an *Aspergillus* sp. in spite of



(a) (b) (c)

Baroda White Onions: (*a*) healthy, (*b*) diseased, (*c*) spores of the malady through oil immersion.

its existence in the soil, has never been found to be parasitic on the living plant. It attacks only the mature bulbs. Observations taken on different modes of storage showed the decay in (1) heaps 47·5%, (2) one layer spread on rice straw 14·6%, (3) store in well-ventilated hanging baskets 15%, and lastly (4) four to five onions woven together by their leaves and hung on a string 15%. Isolated cultures of the organism showed best growth at 34°–35° C. in the multiple incubator.

Walker and Murphy[1] have described an identical rot on onions and garlics imported in the States from Italy. *Botrytis Allii*, Munn. has been long known as Neck Rot of onions both in America and Europe and is seen to attack the inflorescence. The Indian organism seems to differ specifically from the *Aspergillus* described from America. Further observations as to the mode of attack of the organism, its physiology and its response to different methods of storage and chemical treatments are continued.

A Somewhat Cosmopolitan Parasite—*Loranthus longiflorus*.

WITH reference to the article by Mr. Srivastava[1] we wish to point out that at least in Hyderabad the occurrence of *Loranthus longiflorus* on the following host-plants, many of which to our knowledge at least have not been mentioned by previous writers, has long been recorded, but the publication was detained in order to find out as many hosts as possible of this parasite. Mr. Srivastava mentions two of the new hosts which we have recorded.

1. *Psidium guayava.*
2. *Melia azadirachta.*
3. *Cordia myxa.*
4. *Anona squamosa.*
5. *Punica granatum.*
6. *Tamarindus indica* (very rarely).
7. *Citrus aurantium.*
8. *Millingtonia hortensis.*

As has been mentioned by other writers *Loranthus* is a branch parasite and flowers profusely about the months of June and July. The following hosts of *Loranthus longiflorus* are mentioned by different writers. *Bassia latifolia* and *Diospyros Melanoxylon* are recorded by Partridge.[2] Cooke[3] states that it is common on mango trees in Bombay and throughout the Konkan. Duthie[4] mentions that it is parasitic especially on mango, neem and mahua. Hooker[5] mentions nothing about the host-plants of *Loranthus*. Keeble[6] gives a beautiful account of the *Loranthaceæ* of Ceylon describing in detail the fertilization of the flower, mode of distribution of seeds, etc., but does not mention the hosts. Although this parasite is becoming somewhat cosmopolitan it is worth while recording from time to time in different localities on what new hosts it spreads. Evidently there does not seem to be any specialisation of hosts in this parasite.

Nectar fills the corolla-tube in *Loranthus longiflorus*. In addition to this Keeble mentions that " a drop is lodged behind the base of each filament between it and the corolla-lobes". It attracts small insects and birds. The latter seem to be the chief fertilizing agents. Their gentle tap breaks open the corolla-lobes which were hitherto closed. Keeble suggests that " this remaining closed of the ripe flowers is an instance of close relationship, beneficial to both parties, between flower and fertilizer; the bird knows it is worth its while to 'tap a new barrel' as it were; moreover, the parts of the flower are protected from the damaging effects of exposure to wet." It is so indeed. In the majority of the *Loranthaceæ* the seeds are dispersed by the agency of birds and in some cases by the explosions of the fruits as Dr. B. Sahni[7] states. Engler and Prantl[8] in their account of the distribution of the seeds conclude by saying that " The stickiness (of the viscin) enables some seeds, falling from branch to branch, to become attached; on the other hand, birds bite up the fruits and throw away the seed which is surrounded by the viscid layer " and further that seeds often pass unharmed through the gut of birds and may then germinate. Our own observations confirm much of what has been quoted. It is a very common observation that according to the nature of the fruit-coat and the seed that birds reject the former or the latter. In the case of the fruit-coat of *Loranthus* we know that it contains a lot of tannin, and hence it does not appeal to the birds which extract the seed with the pulp from the fruit and reject the coat.

FIG. 1. *Loranthus longiflorus* (Loranthaceæ) parasite on *Melia azadirachta* (Meliaceæ).

FIG. 2. *Loranthus longiflorus* (Loranthaceæ) parasite on *Cordia myxa* (Boragineæ).

Although the birds eat away the pulp and get rid of the seeds by wiping or stricking their beaks against branches or other objects, occasionally some of them are swallowed. Out of these a few pass unharmed through the gut and germinate quite well while others are destroyed by the digestive juices in the gut. However, this fact is an established one that birds are responsible for the dissemination of seeds in *Loranthus*.

As a result of the attack of *Loranthus* on its hosts, outgrowths of considerable size and peculiar complicated shape result. Ultimately the host becomes almost brittle and falls down. Further observations are being made.

Double Parasitism of *Loranthus* and *Viscum* on Eugenia.

Loranthus is a very common parasite of flowering plant all over Western India. It has numerous hosts which include a number of cultivated plants. The species *longiflorus* is the commonest and is found very extensively both on cultivated and wild plants. *Viscum*, on the other hand, is less common and is usually found in thick forests and in shady places. I have never seen *Loranthus* parasitic on Myrtaceæ but a case has recently been reported by Mr. G. D. Srivastava[1]. I am therefore inclined to record another case of a similar kind but still more interesting. In July last I observed a *Loranthus* parasitic on a tall plant of *Eugenia jambolana* and when the specimen was collected I discovered that it has itself been parasitised by *Viscum articulatum*, the *Loranthus* being a parasite directly on Eugenia.

The parasitism of *Loranthus* on Myrtaceæ is certainly rare but such a case of *Viscum* on *Loranthus* and *Loranthus* on *Eugenia jambolana* is certainly very rare and is worth recording. Perhaps such double parasitism is seen in the deeper forests of the Thana District where this plant was found, but I know of no record of the kind.

MOSES EZEKIEL.

Biology Department,
Wilson College, Bombay.
September 4, 1935.

[1] *Curr. Sci.*, 1935, **4**, 106.

N.B.—Since writing the above I saw in the Victoria Gardens, Bombay, *Loranthus longiflorus* parasitic on *Callistemon linearis* (*C. coccinia*, the Australian Bottle Brush), a member of the family Myrtaceæ. This fact is worth noting because *Callistemon* is an introduced garden plant, and more so because this garden is remarkably free from *Loranthus* parasites, this case being one of the very few in the garden.

September 9th, 1935. M. EZEKIEL.

Chromosome Numbers in Two Species of *Hibiscus* (*H. sabdariffa* L. and *H. cannabinus* L).*

THE genus *Hibiscus* belongs to the fairly big family of Malvaceæ which includes a great many familiar plants of cultivation, notably cotton. Cytological work on this economically important family is receiving greater attention in recent times and the work of Davie (1934)[1] gives a comprehensive survey of results obtained. While the cytology of the genus *Gossypium* has been worked out in some detail by several authors that of other genera has not received so much attention. In the genus *Hibiscus* itself only nine species have been examined for their chromosome numbers which reveals polyploidy with high chromosome numbers. The author, while at Pusa, examined cytologically two other species, namely *H. sabdariffa* and *H. cannabinus* for their chromosome numbers and the results are embodied in this note.

Root tips of a pure line of *H. cannabinus* and several varieties of *H. sabdariffa* were fixed in Allen's modification of Bouin's fluids at different times of the day and after the usual dehydration, clearing, and embedding, cut into sections from 10-12μ thick and stained with Haidenhain's Hæmatoxylin. Drawings were made with the aid of a camera lucida at a magnification of 2500. It was found that under conditions obtaining at Pusa, cell divisions started as early as 10 A.M. and continued till 3 P.M. with a maximum phase in the middle, after which there was a cessation and a renewed activity

(*Continued on p.* 175.)

SUPPLEMENT TO "CURRENT SCIENCE".

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Norwich, 1935.

The Presidential Address.

Form, Drift and Rhythm of the Continents.

By Professor W. W. Watts, LL.D., SC.D., F.R.S.,
President of the Association.

IT is now sixty-seven years since the British Association enjoyed the hospitality of the city of Norwich, a privilege which is being renewed to-day under the most happy auspices.

At that meeting we find the scientific community was particularly interested in underground temperatures and tidal phenomena, in the application of the spectroscope to celestial objects, and in the discovery of the oldest Cambrian fossils and the earliest fossil mammals then known. Many papers were read on local natural history, including those on Norfolk farming and the drainage of the County and of the Fens.

In his address at the meeting the President, Sir Joseph D. Hooker, made special reference to the work of Charles Darwin: not to the *Origin of Species* which had been acrimoniously discussed by the Association on previous occasions, and notably at Oxford in 1860, but to some of the work that followed.

It should be remembered that Hooker was one of the three scientific men, representing botany, zoology and geology, whom Darwin had selected as judges with whose opinion on the soundness of his theory of the origin of species he would be content. The others were Huxley and Lyell; and of the three Lyell was the hardest to convince, chiefly because the record of life in the past then furnished by the rocks was manifestly so incomplete and unsatisfactory that its evidence was insufficient to warrant a definite verdict.

Lyell had set out to 'treat of such features of the economy of existing nature, animate and inanimate, as are illustrative of geology,' and to make 'an investigation of the permanent effects of causes now in action which may serve as records to after ages of the present condition of the earth and its inhabitants.' By laborious study of the work of others, and by his own extensive travel and research, he had been able to enunciate, for the inorganic world, the principle of uniformitarianism, which in its original form we owe to Hutton. This principle involved that the history revealed by the rocks should be read as the effect of the slow but continuous operation of causes, most of them small, such as could be seen in action in some part or other of the world to-day. This was set in opposition to the opinion of the older geologists who had postulated a succession of catastrophes which, by flood, fire and convulsion, had periodically wrecked the world and destroyed its inhabitants: each catastrophe necessitating a new creation to provide the succession of life on the earth as it then was known.

But in the organic world Lyell, like Hutton, had failed to detect any analogous principle, and, as he rejected all the theories of transmutation of species then in vogue, he had to accept their absolute fixity; and to suppose that, as species became extinct one after another, replacement by special creations followed. And yet the reading to-day of the chapters devoted to this branch in the earlier editions of Lyell's great work produces the haunting feeling that a better explanation had only just eluded him. It was the story revealed in Lyell's work, Darwin tells us, the new conception that the earth had been in existence for vast æons of time, the proof that it has been continuously peopled by animals and plants, and that these had steadfastly advanced and improved throughout that time, which showed him the necessity for an explanation of the progression of life, and gave him the first hints of his theory. When he had enunciated this he was enabled to repay his master with the principle of organic evolution, which brought changes in the animate world into harmony with those of the inanimate.

His *Antiquity of Man* shows that by

1863 Lyell had become a convert, and he afterwards rewrote much of the second volume of his *Principles* accepting the new point of view. This change earned from Hooker a testimonial in the 1868 address which, if not unique, must certainly be one of the most magnificent ever awarded to a scientific work:

> 'I know no brighter example of heroism, of its kind, than this, of an author thus abandoning, late in life, a theory which he had regarded as one of the foundation stones of a work that had given him the highest position attainable amongst contemporary scientific writers. Well may he be proud of a superstructure, raised on the foundation of an insecure doctrine, when he finds that he can underpin it and substitute a new foundation: and, after all is finished, survey his edifice, not only more secure, but more harmonious in proportions than before.'

Although infinitely richer than when Darwin wrote, the Geological Record still is, and must from its very nature remain, imperfect. Every major group of animal life but the vertebrates is represented in the Cambrian fauna, and the scant relics that have been recovered from earlier rocks give very little idea of what had gone before, and no evidence whatever as to the beginnings of life.

But, from Cambrian time onward the chain of life is continuous and unbroken. Type after type has arisen, flourished and attained dominion. Some of them have met extinction in the heyday of their development; others have slowly dwindled away; others, again, have not finished their downhill journey, or are still advancing to their climax.

Study of the succession of rocks and the organisms contained in them, in every case in which evidence is sufficiently abundant and particularly among the vertebrates and in the later stages of geological history, has now revealed that the great majority of species show close affinities with those which preceded and with those which followed them; that, indeed, they have been derived from their predecessors and gave origin to their successors. We may now fairly claim that palæontology has lifted the theory of evolution of organisms from the limbo of hypothesis into a fact completely demonstrated by the integral chain of life which links the animals and plants of to-day with the earliest of their forerunners of the most remote past.

Further, the rocks themselves yield proof of the geographical changes undergone by the earth during its physical history; and indicate with perfect clearness that these changes have been so closely attendant on variation in life, and the incoming of new species, that it is impossible to deny a relation of cause and effect.

Indeed, when we realise the delicate adjustment of all life to the four elements of the ancients which environ it, air, water, earth and fire; to their composition, interrelationships and circulation; it is perhaps one of the most remarkable facts established by geology that, in spite of the physical changes which we know to have occurred, the chain of life has never snapped in all the hundreds of millions of years through which its history has been traced.

The physical changes with which Lyell and his successors were most closely concerned were, firstly, the formation of stratified rocks on horizontal sea-floors, situated in what is now often the interior of continents, far removed from the oceans of the present day, and thus indicating important and repeated changes in the position of land and water; and, secondly, the deformation of these flat deposits till they were rucked and ridged to build the mountain ranges.

Before and since Lyell's time geologists have devoted themselves to working out the exact and detailed succession of these stratified rocks, translating their sequence into history and their characters into terms of geography; the succession of physical conditions prevailing at the time of their formation. Further, although animals and plants migrate from place to place, the time occupied by the migrations of suitable forms is so negligible when compared with the length of the chapters of geological history that their fossil remains have proved to be the best means for correlating strata over broad stretches of the earth's surface. This correlation has converted the fragments of local history thus revealed into at least the outlines of the geological story of the world.

It was not till 1885, however, that the accumulation of data of this type was sufficient to enable the great geologist, Suess, an Austrian but born in this country, to assemble and correlate them, and to deduce from them further principles which have been the mainstay and inspiration of his successors. We owe to Hertha Sollas and her father the rendering of this great work, *The Face of the Earth*, into English; and to Emmanuel de Margerie and his colleagues a French translation enriched

with a magnificent series of maps and sections such as could only have been brought together by one with the most remarkable bibliographic knowledge; a veritable recension of the original.

The nature and associations and the distribution in time and space of modern changes in the relative levels of land and sea, as detected at sea-margins and by altitude survey, and of older changes betrayed by such evidence as submerged forests and raised beaches, had convinced geologists that the unstable element was not the fickle and mobile sea, but the solid if elastic earth-crust. They naturally applied the same explanation to those encroachments of the sea in the past which had resulted in the formation of our stratified rocks. But while some investigators were content with one form of movement—that due to lateral pressure—to explain both the formation of mountains and the rise and fall of the land, others called in a different cause for the latter. Without entering into a discussion of causes it may be well for us to distinguish the orogenic or mountain-forming from the epeirogenic or continental movement.

The evidence collected by Suess proved that these last great land and sea changes had occurred simultaneously over whole continents or even wider regions. Such great submergences as those to which the Cambrian Rocks, the Oxford Clay and the Chalk are due were of this character; while, in between, there came times of broad expansions of continental land and regressions of the sea. These changes were in his view on far too grand a scale to be compared with, or explained by, the trivial upheavals and depressions of land margins of the present day, which he showed could mostly be correlated with volcanoes or earthquakes, or with such incidents as the imposition or relief of ice-sheets on an elastic crust in connexion with glacial conditions.

It became necessary for him to replace or supplement oscillations of the earth-crust by a world-wide periodic ebb and flow of the oceans, to and from the continents; positive movements of transgression carrying the sea and its deposits over the lands, drowning them and their features under tens or hundreds of fathoms of water; and negative movements or regressions when the oceans retreated to the deeps, leaving the continents bare or encrusted with recently formed sediments.

Although the facts cried out for this generalisation Suess was at a loss to supply any mechanism competent to produce the wonderful rhythm. The problem was difficult because a liquid must maintain a horizontal, *i.e.*, an equipotential, surface. It was manifestly impossible to withdraw from the earth, and later to replace upon it, the vast quantity of water that would be required; and, though a shifted water-level, or even a varied water-surface relative to the continents, might be caused by polar ice-caps, by redistribution of the continents carrying their local effects on gravitation, by variations in the rate of the earth's rotation, or other far-reaching causes, none of these would supply an explanation that fitted all the facts. Regressions of the sea could be to some extent explained if Suess's main postulate, that the great ocean basins had been slowly sinking throughout geological time, were granted. But this explanation only rendered more impotent the raising of ocean levels by deposits of sediment, and this was almost the only valid cause for transgressions that he had been able to suggest.

Further, it is not possible to ignore the definite relationship that exists between the pulsation of the oceans and the raising of mountains by lateral or tangential stress. Periods of positive movement or advance of the seas were times of comparative tranquillity, when tangential pressure was in abeyance. Periods of negative movement and retreat were invariably marked by the operation of great stresses by which the earth's face was ridged and wrinkled in the throes of mountain-birth.

The theory that continuous cooling and shrinkage of the interior of the earth afforded an explanation of mountain ranges and other rugosities on its surface was a legacy from the nebular hypothesis. In spite of the homely simile of a shrivelling apple, this explanation has never received a very enthusiastic welcome from geologists, though, in default of other resources, they had to make use of it. As knowledge has grown the difficulties have become insurmountable to them.

First, there is its inadequacy to explain the vast amount of lateral movement required to account for the greater mountain ranges; their rocks, originally spread over a wider area, having been folded and crushed into a narrower width. The shortening of the earth-crust thus effected has been estimated in the case of the Rocky Mountains at 29

miles, of the Himalayas at 62, the Alps at 76, and the Appalachians at the large figure of 200 miles.

Then there is the periodicity of mountain growth. The great epochs of mountain-building, such as the Caledonian, to which the chief Scottish and Welsh mountains are due, the Hercinian, responsible for the Pennine and South Wales, and the Alpine, which gave us 'the wooded, dim, blue goodness of the Weald,' were associated with vast continental development; and each was separated from the next by a period of relative inactivity lasting dozens of millions of years.

Further, there is the fact that the vigour of mountain-building, of volcanoes, and of other manifestations of unrest, has shown no sign of senility or lack of energy. The geologically recent Alpine-Himalayan range is as great, as lofty, and as complicated in structure, as were any of its precursors. The active volcanoes of Kilauea, Krakatao, or St. Pierre, and those recently extinct in Northern Ireland and the Scottish Isles, were as violent and efficient as any of those of the Palæozoic Era. The earth is 'a lady of a certain age,' but she has contrived to preserve her youth and energy as well as her beauty.

But it was when Lord Kelvin's dictum struck from geology its grandest conception, time, that it became vital to re-examine the position. He had demonstrated that, if the earth had been continuously cooling down at its present rate, its surface must have been too hot for the existence of life upon it a limited number of million years ago. The concept of geological time, indicated by Hutton in his famous saying that in this enquiry 'we find no vestige of a beginning —no prospect of an end,' had been confirmed by data accumulated through the painstaking researches of a host of competent and devoted observers all over the world. To them, familiar with the tremendous changes, organic and inorganic, that the earth had passed through since Cambrian time, it was wholly impossible to compress the life story of the earth, or the history of life upon it, into a paltry 20 or 30 million years. The slow growth and slow decay of mountain range after mountain range, each built out of, and in some cases upon, the ruins of its predecessor; the chain of slowly evolving organisms, vast in numbers and infinite in variety; told plainly of long æons of time. And the duration of these æons can be dimly realised when it is recalled that, within a small fraction of the latest of them, man, with the most primitive of implements and the most rudimentary culture, has succeeded in penetrating to the uttermost corners of the world, and developed his innumerable languages and civilisations.

Huxley, as our representative, took up the challenge in his address to the Geological Society in 1869, and asked the pertinent question "but is the earth nothing but a cooling mass 'like a hot water jar such as is used in carriages' or 'a globe of sandstone'?" And he was able to point out at least some agencies which might regenerate the earth's heat or delay its loss.

So it is only fitting that the great physicist, who imposed a narrow limit to geological time, should have prepared the way for those who have proved that the earth possesses in its radioactive substances a 'hidden reserve' capable of supplying a continuous recrudescence of the energy wasted by radiation, thus lengthening out the time required to complete its total loss. These later physicists have given us time without stint; and, though this time is the merest fraction of that envisaged by cosmogonists and astronomers, we are now so much richer than our original estimates that we are embarrassed by the wealth poured into our hands. So far from the last century's urge to 'hurry up our phenomena,' we are almost at a loss for phenomena enough to fill up the time.

The far-sighted genius of Lord Rutherford and Lord Rayleigh first saw the bearing of the rate of disintegration of radioactive substances in the minerals of rocks on the age of the parts of the earth-crust built of them. The extension and supplementing of this work by Joly, Holmes, and others, has now enabled us to look to the disintegration of uranium, thorium, and potassium, as the most promising of many methods that have been used in the endeavour to ascertain the age of those parts of the earth-crust that are accessible to observation. These methods also promise a means of dating the geological succession of Eras and Periods in terms of millions if not hundreds of thousands of years.

The decline and early death to which Lord Kelvin's dictum had condemned the earth, according so little with the vigour displayed in its geological story, is now transformed into a history of prolonged though not perennial youth. It was for

Joly, of whose work the extent, variety and fruitfulness are hardly yet fully appreciated, to take the next step and see in the release of radioactive energy a mechanism which could drive the pulse that geologists had so long felt, and that Suess had so brilliantly diagnosed. As Darwin found the missing word for Lyell, so Joly in his theory of Thermal Cycles has indicated the direction of search for a mechanism to actuate the rhythm of Suess.

In Joly's conception the running down of the earth's energy, though a continuous process, was, through the intervention of radioactivity, converted into a series of cycles, during each of which relative movements of sea and land must occur; downward movements of the continents, associated with positive encroachments of the sea; upward movements, with retreat of the sea, the formation of wide land masses, and the ridging of strata to form mountain ranges. Thus he forged a link that could unite the continental or epeirogenic movement with orogenic or mountain movement.

The visible parts of mountains and continents, as well as their lower and hidden portions, or 'roots', are made of comparatively light rocks. In order to stand up as they do their roots must be embedded in denser matter, in which they 'float' like ice-bergs in water. A far larger mass must exist below than is visible above, and the bigger the upstanding part the bigger the submerged root. Over the larger area of the ocean floor, on the other hand, the thickness of material of low density must be very slight, and the denser layer must come close to the surface.

The study of earthquakes, to which the Seismology Committee of the British Association has made outstanding contributions, has yielded, from the times taken in transmission of vibrations through the earth, the best information as to the nature and state of the interior. It has proved that the dense layer is solid at the present time. It is probably no coincidence that the earth is also but just recovering from what is possibly the greatest period of mountain-building, if not the greatest negative movement of ocean retreat, that it has ever experienced.

But solidity cannot be the permanent condition of the substratum. Heat is generated in it by its own radioactivity, but, according to the terms of the hypothesis, cannot escape, in consequence of the higher temperature generated in the continental rocks which cover it. It is therefore retained in the substratum and stored as latent heat of liquefaction, so that, within a period which has been calculated approximately in millions of years, complete melting of the sub-crust must ensue.

The resulting expansion of the liquefied stratum will have at least two effects of great importance to us. In the first place the unexpanded superficial layers will be too small to fit the swelling interior. They will, therefore, suffer tension, greater on the ocean floor than on land, and cracking and rifting will occur, with intrusion and extrusion of molten rock. In the second place the continental masses, now truly floating in a substratum which has become fluid and less dense than before, will sink deeper into it, suffering displacement along the rift cracks or other planes of dislocation. As a result the ocean waters, unchanged in volume, must encroach on the edges of the continents, and spread farther and farther over their surfaces.

Thus we have the mechanism which Suess vainly sought, causing positive movements of the oceans, their waters spreading over wide stretches of what was formerly continental land, and laying down as sediment upon it the marine stratified rocks which are our chief witness of the rhythmic advances of the sea.

This condition, however, cannot be permanent, for by convection of the fluid basic substratum, supplemented by the influence of tides within it, and the slow westward tidal drag of the continental masses towards and over what had been ocean floor, there will now be dissipation of its heat, mainly into the ocean waters, at a rate much faster than it has been or could be accumulated. Resolidification ensues, and again there are two main consequences. First, the stratum embedding their roots having now become more dense, the continental masses rise, and as they do so the ocean waters retreat from their margins and epicontinental seas, leaving bare as new land, made of the recently deposited sediments, the areas previously drowned. Secondly, the expanded crust, left insufficiently supported by the withdrawal of shrunken substratum, will suffer from severe tangential stress, and, on yielding, will wrinkle like the skin of a withering apple. The wrinkles will be mountain ranges, formed along lines of weakness

such as those at continental margins; and they will be piled up and elevated to suffer from the intense erosion due to water action upon their exposed and upraised rocks.

In this, again, we have a mechanism which supplies what was needed by Suess, and one, moreover, which secures the required relationship between continental and mountain movement, between the broader extensions of continental land and the growth of mountains with their volcanoes and earthquakes and the other concomitants of lateral thrust.

Thus a Thermal Cycle may run its full course from the solid substratum, through a period of liquefaction accompanied by crustal tension, back to solidification and an era of lateral stress: and the stage is set for a new cycle.

Professor Arthur Holmes, in checking Joly's calculations, has concluded that the length of the cycles in a basic rock substratum should occupy from 25 to 40 million years, a period much too short to fit the major periods of mountain movement, as determined by him from the radioactivity of minerals contained in the rocks. On this evidence the Alpine movement should date back from 20 to 60 millions of years ago, the Hercynian 200 to 250 millions, and the Caledonian from 350 to 375 million years.

In a preliminary attempt to modify Joly's hypothesis Holmes postulated the occurrence of similar, but longer cycles (Magmatic Cycles) in a denser, ultrabasic layer underlying the basic one, the rhythm of which would be nearer to 150 million years. The shorter cycles due to the basic layer are held in part responsible for periods of minor disturbance, and also to account for the individual variations in effect, duration, and intensity of the larger ones. Each of the later movements has also evidently been limited and conditioned by the results of foregoing ones, and especially by areas of fracture and weakness on the one hand, and by large stable masses composed of rocks intensely consolidated, or already closely packed, on the other.

More recently Holmes has developed the possibility that the loss of heat is mainly due to convection in the liquid substrata, and that convection is the leading cause of the drifting and other movements of the crust, and the disturbances that have occurred in it. He says:—

'Although the hypothesis involving sub-crustal convection currents cannot be regarded as established, it is encouraging to find that it is consistent with a wide range of geological and geophysical data. Moreover, it is by no means independent of the best features of the other hypotheses. It requires the local operation of thermal cycles within the crust, and it necessarily involves contraction in regions where crustal cooling takes place. It is sufficiently complex to match the astonishing complexities of geological history, and sufficiently startling to stimulate research in many directions.'

The phenomena are difficult to disentangle as the number of operating causes has been so great and many of them are not fully understood. But, underlying them all there is unquestionably the pulse within pulse which Suess saw and of which Joly pointed the way to explanation.

The view at which we have arrived is neither strictly uniformitarian nor strictly catastrophic, but takes the best from each hypothesis. As Lyell showed, most of the phenomena of geology can be matched somewhere and sometime on the earth of to-day; but it would appear that they have varied in place, intensity, phase, and time. And, as Lyell was driven to accept *evolution* to explain the history of life on the earth, so must we employ the same word to express the life-processes of the earth itself, as was suggested by Huxley in 1869 and strongly advocated by Sollas in 1883.

The contrast in outline and structure between the Atlantic and Pacific Oceans had long been noted when Suess formulated and used the differences as the basis of his classification.

The Pacific is bounded everywhere by steep slopes, rising abruptly from profound ocean depths to lofty lands crowned with mountain ranges, parallel to its shores and surrounding its whole area. On the American side the Coast Range is continued by the Andes. On the Asiatic side chains of mountainous peninsulas and islands, separated from the continent by shallow inland seas, extend in festoons from Kamchatka and Japan to the East Indies, eastern Australia and New Zealand. This mountain ring, as Charles Lapworth said, 'is ablaze with volcanoes and creeping with earthquakes,' testifying that it has been recently formed and is still unfinished.

The Atlantic Ocean, on the other hand, is not bordered with continuous ranges, but breaks across them all: the Scottish and Welsh ranges, the Armorican range, the continuation of the Pyrenees and Atlas; and, on the American side, the uplands of

Labrador, Newfoundland and the eastern States, and the hill ranges of Guiana and Brazil. The Atlantic is in disconformity with the grain of the land, while the Pacific conforms with it. The Pacific has the rock-folds of its ranges breaking like ocean waves towards it as though the land were being driven by pressure to advance upon it, while the Atlantic recalls the effects of fracture under tension.

The middle and southern edges of the Atlantic, however, agree to some extent with the Pacific type. The Caribbean Sea, with the Antilles and the rest of its border girdle, recalls the similar structure of the Mediterranean, as it stretches eastwards, with breaks, to the East Indian Archipelago; while the Andes are continued to Antarctica in a sweeping curve of islands. The rest of the Indian Ocean is of Atlantic type, as seen in the shores of eastern Africa and western Australia.

Another feature of the Atlantic is the parallelism of much of its eastern and western coasts, the meaning of which has often attracted the speculations of geologists and geographers. With a little stretch of the imagination, and some ingenuity and elasticity of adjustment, plans or maps of the opposite sides may be fitted fairly closely, particularly if we plot and assemble the real edges of the continents, the steep slopes which divide the 'shelves' on which they stand from the ocean depths. This has suggested the possibility that the two sides may once have been united, and have since broken and drifted apart till they are now separated by the ocean.

This view, outlined by others, has been emphasised by Wegener and dealt with by him in full detail in his work on *The Origin of Continents and Oceans*, and it now plays a leading part in what is known as the Wegener theory of continental drift. The hypothesis is supported by the close resemblances in the rocks and fossils of many ages in western Europe and Britain to those of eastern North America; by community of the structures by which these rocks are affected; and by the strong likeness exhibited by the living animals and plants on the two sides, so that they can only be referred to a single biological and distributional unit, the Palæarctic Region.

The hypothesis, however, did not stop at this; and in the South Atlantic and certain other areas Wegener and his followers have also given good reasons for believing that continental masses, once continuous, have drifted apart.

Broad areas in southern Africa are built of rocks known as the Karroo Formation, of which the lower part, of late Carboniferous age, is characterised especially by species of the strange fern-like fossil plants Glossopteris and Gangamopteris. Associated with them are peculiar groups of fossil shells and fossil amphibia and reptiles. Similar rocks, with similar associations and contents, in Peninsular India have been named the Gondwana Formation. Comparable Formations also occupy large regions in Australia, Tasmania and New Zealand, in Madagascar, in the Falkland Islands and Brazil, and in Antarctica.

The correspondence between these areas is so close that Suess supposed they must at that date have been connected together by lands, now sunk beneath the sea, and he named the continent thus formed Gondwanaland after the Indian occurrences. The break-up of this land can be followed from a study of the rocks, and it was a slow process, its steps occupying much of Mesozoic time. Dr. A. L. du Toit's comparison of South African rocks with those of Brazil and elsewhere in South America favours even a closer union than this between the units now scattered.

One of the most remarkable features shown by these rocks in all the areas mentioned, but to varying extents, is the presence of conglomerates made of far-travelled boulders, scratched like those borne by the modern ice-sheets of Greenland and the Antarctic, associated with other deposits of a glacial nature, and often resting upon typical glaciated surfaces. There is no possible escape from the conclusion that these areas, now situated in or near the tropics, suffered an intense glaciation. This was not a case of mere alpine glaciers, for the land was of low relief and not far removed from sea-level, but of extensive ice-sheets on a far larger scale than the glaciation of the northern parts of the new and old worlds in the Pleistocene Ice Age. I have never seen any geological evidence more impressive or convincing than that displayed at Nooitgedacht, near Kimberley; while the illustrations and other evidence published by David and Howchin from Australia are equally striking.

Du Toit's work on these glacial deposits brings out two remarkable facts; first, that the movement of the ice was southerly, poleward and away from the equator, the

opposite to what would be expected, and to the direction of the Pleistocene ice-movement; secondly, that the ice in Natal invaded the land from what is now sea to the north-east.

When it is realised that at this period there is no evidence of glacial action in northern Europe or America, but a climate in which grew the vegetation that formed the coal seams of our Coal Measures, it is clear that we are not dealing with any general refrigeration of the globe, even if that would produce such widespread glaciation: we are face to face with a special glaciation of Gondwanaland.

On both sides of the Atlantic these glacial episodes in Carboniferous times were followed by dry and desert climates in Triassic time, and these by violent volcanic outbursts. Nor are the rocks alike only in mode of formation, the structures by which they are traversed correspond; while even in details there is remarkable agreement, as in the peculiar manganese deposits, and the occurrence of diamonds in 'pipes' of igneous rock, both east and west of the Ocean.

Rather than face the difficulties presented by the subsidence of lands connecting the severed portions of Gondwanaland, as pictured by Suess, Wegener has preferred, and in this he is supported by Du Toit and many other geologists, to bring into contact these severed parts, which could be fitted together as nearly as might be expected, considering the dates of severance. Du Toit's map of the period places South America to the west and south of South Africa, Madagascar and India to the east, Antarctica to the south, and Australia farther to the south-east. Such a grouping would form a continent much less wide in extent than that envisaged by Suess, and would offer some explanation of the more remarkable features of the glaciation in the several areas, as well as the problems of the rocks, fossils, and structures involved.

In its application to the geology of Gondwanaland the modified hypothesis of Wegener cuts a Gordian knot; but it still leaves a great climatal difficulty, unless we take his further step and conceive that at this date the terrestrial south pole was situated within Gondwanaland. No shift in the axis on which the earth rotates would, of course, be possible, nor is it postulated: only a drifting at that date of continental land across the pole.

If a hypothesis of drift be admitted for Gondwanaland, it would be illogical to deny its application to other regions, including the north Atlantic. I have already mentioned some facts in its favour. Others are the resemblances of all sedimentary rocks on the two sides from the Cambrian to the Ordovician, and from the Devonian to the Trias; the links between the structures of the land, as, for instance, between Ireland and Newfoundland; and the instance given by Professor Bailey in his address to Section C in 1928. As Bailey then pointed out, the great Caledonian range which crosses Scotland, northern England and Wales from north-east to south-west on its course from Scandinavia is affected and displaced by the east to west Armorican (Hercynian) chain extending across from Brittany to South Wales. 'The crossing of the chains, begun in the British Isles, is completed in New England'; and from here the Armorican structure continues its westerly course. This is where it should cross if the continent of North America were brought back across the Atlantic and placed in the position which, according to Wegener, it would fit into in the European coast! Can the Pilgrim Fathers have ever dreamed of such a link between the Old England and the New?

The hypothesis of continental drift gave rich promise of solving so many difficult problems that it was hailed by many classes of investigators almost as a panacea. Geographers have seen in it an explanation of the forms of continents and the position of peninsulas, islands and mountains; meteorologists have found it the solution of some of the problems of past climates and their anomalies of distribution over the world; biologists hope to get help with the intense complexities in the distribution of forms of life and many strange facts in migration, and palæontologists with similar difficulties among the ancient faunas and floras as revealed by their fossil remains; geodesists have welcomed escape from the rising and sinking of the crust, so difficult to reconcile with the demands of isostatic equilibrium; and it has been already stated that drift forms a vital factor in Joly's thermal cycles.

But there has been no lack of criticism in all these directions. It has been assailed on the one hand for the detail attempted in its geographical restorations, and on the other hand for its vagueness. Prof. Schuchert quotes Termier as saying that it is 'a beautiful dream, the dream of a great poet. One tries to embrace it, and finds that he has in

his arms but a little vapour or smoke: it is at the same time alluring and intangible.' It has been objected that 'no plausible explanation of the mechanics involved has been offered'; that the continental connexions postulated present by no means so close a match, when fitted together, as has been claimed, in the structure or the nature of either igneous or sedimentary rocks; that there is good evidence of extensive vertical movements in recent earthquakes, in the accumulation of tremendous thicknesses of sediment indicative of shallow-water from base to summit, and in the growth of coral reefs; that Central America and the Mediterranean are a difficult obstacle; and that the known distribution of the Karroo fossil reptiles is not by any means what the hypothesis demands.

If the idea of drift be accepted it cannot be regarded as a royal road out of all our difficulties, nor can it be the only form of earth-movement to be reckoned with. The late J. W. Gregory, whose life was sacrificed to geological discovery, has studied exhaustively the geological history of the Atlantic and Pacific Oceans, both as revealed by the sedimentary rocks and fossils on their borders, and by the distribution of life to-day. He finds that, according to our present knowledge, in the two oceans, facilities for migration have fluctuated from time to time, periods of great community of organisms alternating with periods of diversity. Again, at some times connexion seems to have been established north of the equator, at others to the south; and we cannot ignore the possibility of migration across polar lands or seas when terrestrial climates have differed from the present. The facts of life distribution are far too complex to be explained by any single period of connection followed by a definite breaking apart, even if that took place by stages. Mrs. Reid, too, has pointed out that resemblances between the Tertiary floras of America and Europe actually increased at the time when the Atlantic should have been widening. Unless continental drift has been a more complicated process than anyone has yet conceived, it seems impossible to escape from some form of the 'land bridges' of the older naturalists:

'Air-roads over islands lost—
Ages since 'neath Ocean lost—'

We have no right to expect greater simplicity in the life of a planet than in that of an organism.

As the question of drift must in the last appeal be one of fact, it is not unnaturally expected that the real answer will come from measurements of longitude and latitude with greater exactness and over periods longer than has yet been possible. None of the measurements hitherto made has indicated variations greater than the limits of errors of observation. Two things, however, may militate against a definite answer from this source. Many parts of the crust, such as the shield-like masses of Archæan rock, may have completed their movement, or be now moving so slowly that the movement could not be measured. Careful selection of locality is essential, and at present we have little guidance. Also, as the displacement of crust must be dependent on the condition of its substratum, it will be a periodic phenomenon and the rate of movement may vary much in time. According to the theory of thermal cycles the subcrust is at present solid, and may not permit of drift. Drift, according to Joly and Holmes, is a cyclical phenomenon; if present-day observations were to give a negative result they would not necessarily disprove it.

The occurrence of recumbent rockfolds, and nearly horizontal slides or 'nappes' in mountain regions, gives positive proof that parts of the upper earth-crust have moved over the lower. In the North-west Highlands of Scotland a sliding of at least ten miles was proved by Peach and Horne, and in Scandinavia it amounts to sixty miles. For mountain packing as a whole the figures already given are far larger, while in Asia Argand has stated that packing of over 2,000 miles has occurred. Thus, when all is said and done, movements on a colossal scale are established facts, and the question of the future is how far we shall accept the scheme of drift due to Wegener, or one or other of the modifications of it. It is for us to watch and test all the data under our own observation, feeling sure that we shall have to adapt to our own case Galileo's words 'e pur si muove'.

Ever since it was realised that the inclination and folding of rocks must be attributed to lateral or tangential stress and not solely to uplift, shrinkage of the interior of the earth from its crust has been accepted as the prime mover, and whichever of the current theories we adopt we cannot deny the efficacy of so powerful a cause.

The general course of events in the formation of a mountain range is fairly well known;

the slow sinking of a downfold in the crust during long ages; the filling of this with sediment *pari passu* with the sinking, and associated softening of the sub-crust due to accumulated heat; the oncoming of lateral pressure causing wave-like folds in the sediments and the base on which they rest; the crushing of folds together till, like water waves, they bend over and break by overdriving from above or, it may be, underdriving from below; fracture of the compressed folds and the travelling forward for great distances of slivers or 'nappes' or rock, generally of small relative thickness but of great length and breadth, and sliding upon floors of crushed rock; the outpouring and intrusion of igneous rocks, lubricating contacts and complicating the loading of the sediments; metamorphism of many of the rocks by crystallisation at elevated temperatures and under stress, with the development of a new and elaborate system of planes of re-orientation and movement; and elevation of the whole, either independently or by thickening with compression and piling up to bring about a fresh equilibrium.

Such a course of events would be brought about by lateral pressure developed during the consolidation phase of each of the thermal or magmatic cycles. At each period of their building, mountains have arisen along lines of weakness in the crust, especially coast lines and the steep slopes marking the limits between continents and ocean basins. This is consistent with Joly's theory that the thrust of ocean beds against land margins is the cause.

But the advocates of continental drift point to the siting of ranges across the paths along which the drifting movement is supposed to have occurred, and they consider that the moving masses are responsible; and indeed that the ridging and packing of the crust has in the end checked and stopped the movement. They note that the great western ranges of America occur in the path of any western drift of that continent, the Himalayas in the course of the postulated movement of India, the East Indies in front of Australia; and that the Alpine ranges of Europe may be linked with the crushing of Africa towards the north.

The 'nappes' of rock, cut off from their origin and sliding for dozens of miles, are a constant source of wonder to all who have considered the mechanics of mountain formation. They are so thin as compared with their great length and breadth, that it seems impossible to imagine them moved by any force other than one which would make itself felt throughout their every particle. Such a force is gravitation, and it is of interest that some Alpine geologists and Dr. Harold Jeffreys have used it in explanation of them. Professor Daly has also adopted gravitation on an even greater scale in his theory of continental sliding: and one cannot fail to notice the increasing use of the term 'crust-creep' by those working on earth-movement.

Is there no other force, comparable in its method of action to gravitation, but capable of producing movement of the earth-crust in a direction other than downhill? Is it not possible, for instance, that the tidal influence of the moon and sun, which is producing so much distortion of the solid earth that the ocean tides are less than they would be otherwise, and, dragging always in one direction is slowing down the earth's rotation, may exert permanent distorting influence on the solid earth itself? May it not be that such a stress, if not sufficiently powerful to produce the greater displacements of continental drift and mountain-building, may yet take advantage of structures of weakness produced by other causes, and itself contribute to the formation of nappes and to other movements of a nature at present unexplained?

Our knowledge of geology has been gained by the survey of the rocks, the study of their structures, and the delineation of both upon maps and sections. This work is being accomplished by geologists all over the world, and this country and its dependencies have contributed their full share. It is therefore opportune to note that there has just been celebrated the Centenary of the Geological Survey of Britain and, with it, the opening of the new Geological Museum at South Kensington.

A century ago H. T. de la Beche, one of the devoted band of pioneer workers then studying the geology of the country, offered to 'affix geological colours to the new maps of Devon and Cornwall' then in course of issue by the Ordnance Survey. His offer was accepted, and, at his own expense and on his own feet, he carried out a geological survey of some 4,000 square miles. In 1835 he was appointed to continue this task, with a small salary and a few assistants. Thus was started the first official geological survey, an example widely followed by other nations

and dominions. De la Beche's conception included also a Museum of economic and practical geology, a Library, a Record of Mines, for which he secured support from a strong Committee of the British Association in 1838, and a School of Mines for the scientific and technical education of those to be employed in the survey or exploitation of mineral resources. In these objects, and especially the last, he was warmly supported by the Prince Consort. He lived to see his visions all come true, as he collected round himself that wonderful band of surveyors, investigators, writers and teachers, which included such men as Playfair, Logan, Ramsay, Aveline, Jukes, Forbes, Percy, Hooker and Huxley.

Some of the schemes he planned have budded off and grown into large and important entities, rendering conspicuous service to scientific record, education and research. But the main duties of the Geological Survey remained with it, and have been carried on for a century. These are to map the geology of the country on the largest practicable scale, to describe and interpret the structure of the land, to preserve the evidence on which conclusions have been founded, and to illustrate for students and other workers the geology of the country and its applications to economics and industry. The broad detail of the structure of the whole country is now known, but much new work must be done to keep abreast of or to lead geological thought. For instance, the study of the cloak of 'superficial deposits,' which often cover and conceal the structure of the more solid rocks below, is essential for the proper understanding of soils and agriculture; and a knowledge of the deep-seated geology of the country, which is often widely different from that nearer the surface and thus very difficult to interpret, is vital to the community for the successful location and working of coal and iron, and for tracing supplies of water and oil and other resources at depth.

Evolution of life on the earth has been by no means uniform; there have been periods of waxing and waning which may be attributed to geographical, climatological and biological influences. The development of large land areas, ranged longitudinally or latitudinally, the invasion of epicontinental seas, the isolation of mediterraneans or inland seas, the splitting of continental areas into archipelagoes or the reunion of islands into continuous land, the making of barriers by the rearing of mountain chains or the formation of straits or arms of the sea, the oncoming of desert or glacial climates; all such factors and many others have been of importance in quickening or checking competition, and in accelerating or retarding the evolution of life.

Probably, however, even greater effects have followed the interaction of groups of biological changes on one another. As an instance I might recall Starkie Gardner's estimate of the results following upon the first appearance of grasses in the world. This seems to have been not earlier than Eocene, and probably late Eocene times. By the Oligocene they had made good their hold, peculiarities in their growth and structure enabling them to compete with the other vegetation that then existed; and gradually they spread over huge areas of the earth's surface, formerly occupied by marsh, scrub and forest. They have, as Ruskin says, 'a very little strength....and a few delicate long lines meeting at a point. . . made, as it seems, only to be trodden on to-day, and to-morrow to be cast into the oven'; but, through their easy growth, their disregard of trampling and grazing, and by reason of the nourishment concentrated in their seeds, they provided an ideal and plentiful source of food. On their establishment we find that groups of animals, which had previously browsed on shrubs and trees, adopted them, with consequent alterations and adaptations in their teeth and other bodily structures. To follow their food from over-grazed or sun-scorched regions they required to be able to migrate easily and quickly, and it was essential for them to discard sedentary defence and to flee from threatened danger. Such defence as was possible with heels, teeth, or horns, they retained; but the dominant modifications in their organisation were in the direction of speed as their most vital need.

Side by side with this development, and in answer to increasing numbers, came bigger, stronger and speedier carnivores, to feed on prey now so much more abundant, but more difficult to catch. The answer of the grass-feeders, with their specialised hoofs, teeth and bones, better suited to flight than fight, was to seek safety in numbers, and thus develop the herd instinct, with its necessity for leadership and discipline; but this, in turn, provoked a like rejoinder from some types of their enemies.

When it is remembered how much of the

meat and drink and life of mankind is bound up with the grasses, including wheat, maize, millet and other grains, sugarcane, rice and bamboo, we must realise how close is his link with the development just outlined. Practically his whole food supply is provided by them, either directly by the agriculturist who grows little else but grasses, or indirectly by the herdsman whose domestic animals are fed chiefly on the same food. Nor must we forget that almost every one of our domesticated animals has been derived from the gregarious types just mentioned, which have accepted the leadership of man in place of that of their own species.

It is perhaps not too much to say that the magnificent outburst of energy put out by the earth in the erection of the Alps, Andes, and Himalayas in Tertiary times was trivial in its influence for man's advent and his successful occupation of the earth in comparison with the gentle but insidious growth of 'mere unconquerable grass' and its green carpet of 'wise turf' which in some form clothes by far the greater part of the land of the globe.

The kind of developmental reaction of which this is but a single example must clearly have had influence on bodily features, other than bones and horns, teeth and claws, speed and strength; and one of the most striking has been on intellectual development and the size and shape of brain.

We do not, and perhaps can never, know the quality of the material of which the brains of fossil creatures was made, for we have no instrument to pierce the veil of time as the spectroscope has penetrated the abysm of space. But we are even now learning something about their shapes and convolutions, and more about their mass in its relation to the size of the bodies controlled; from the time of the earliest Ordovician fishes, through the history of the amphibia, reptiles, birds and mammals up to man himself.

The brain of those gigantic if somewhat grotesque reptiles the dinosaurs, the tyrants of Mesozoic time, is relatively tiny. In Diplodocus, 80 feet in length and 20 tons in weight, the brain was about the size of a large hen's egg. It is true that there was a big supplementary sacral ganglion which may have taken chief charge of locomotion and helped to secure co-ordination throughout the hinder part of its huge length and bulk; but of true brain there was not more than a quarter of an ounce to control each ton of body and limb; and we begin to understand why they lost the lordship of creation.

The proportion of brain to body improved in those reptiles which took to flying, possibly in relation to their acquisition of warm blood, and in the birds evolved from reptiles; but it is only in mammals that a marked advance is seen. Here the brain of Uintatherium, a great rhinoceros-like animal of Eocene date, weighing 2 tons, was about the size of that of a dog. This proportion of half a pound of brain to each ton of body shows how far the mammals had gone, and still had to go.

A 12-stone man of the present day has about 3½ pounds of brain—an amount not far short of half a hundredweight per ton.

Even though we can know nothing of its material, this steadfast growth in the guiding principle, through the millions of centuries that have gone to its development, is surely one of the most remarkable conclusions that we owe to geology. Of all the wonders of the universe of which we have present knowledge, from the electron to the atom, from the virus and bacillus to the oak and the elephant, from the tiniest meteor to the most magnificent nebula, surely there is nothing to surpass the brain of man. An instrument capable of controlling every thought and action of the human body, the most intricate and efficient piece of mechanism ever devised; of piercing the secrets and defining the laws of nature; of recording and recalling every adventure of the individual from his cradle to his grave; of inspiring or of ruling great masses of mankind; of producing all the gems of speech and song, of poetry and art, that adorn the world, all the thoughts of philosophy and all the triumphs of imagination and insight: it is indeed the greatest marvel of all.

And when we contemplate the time and energy, the sacrifice and devotion, that this evolution has cost, we must feel that we are still far from the end of this mighty purpose: that we can confidently look forward to the further advance which alone could justify the design and skill lavished on this great task throughout the golden ages that have gone.

with another maximum division phase at 11 P.M. thereby showing a periodicity in mitosis. A number of somatic metaphase plates were counted in the two species and in each case the number was found to be 72 (Figs. 1 to 4). A preliminary examination of chromosome complements in the two species revealed certain morphological differences. The chromosomes were thicker and longer in *H. sabdariffa* than those in *H. cannabinus* and in the former species there was a greater number of U- and V-shaped chromosomes (Figs. 1 to 3) while in the latter there was greater number of rod-like chromosomes.

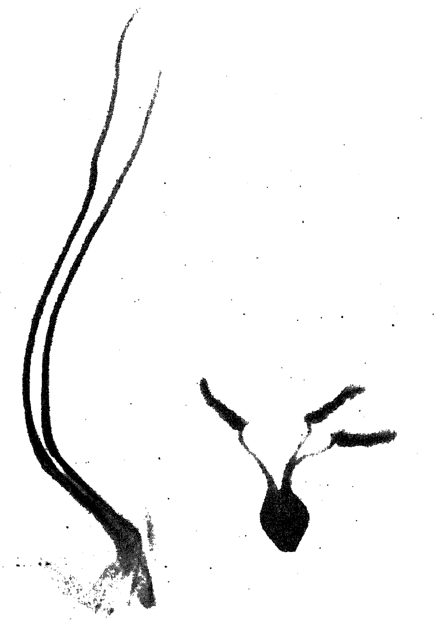
Further Data on the Homology of Stigmas and Awns.

In a previous paper (G. N. Rangaswami Ayyangar and V. P. Rao, 1935)[1] the homology of stigmas and awns was dilated upon. In this note further data obtained is presented.

The first experience is from a very rare phenomenon in a family of sorghum in which the awns instead of being single, forked into two (Fig. 1). A careful examination of the stigmas was made with a view to look out for any possible repercussions of this forking of the awn. In one instance, three stigmas were noted (Fig. 1), with no aberrations in the ovary. According to Walker (1906)[2] in the tricarpellate pistils of *Andropogoneæ* two of the carpels normally form the bulk of the ovary and bear the style branches while the third carpel bears



Forked Awn. Forked Stigma.

Fig. 1.

the ovule. The photograph of the forked style is unmistakable in its import. Few and feeble as the response of the stigma has been, it is nevertheless significant.

The second evidence, derived from a cross between *Sufra*, a variety of sorghum from the Sudan and *Chinna Manjal Cholam*, a Coimbatore variety, is telling. In *Sufra*, which is awnless, the length of the stigma and style is unequal. *Chinna Manjal Cholam* has awns in which the column and the subule are of equal length. So also the stigmatic and stylar lengths. The F_1 was awnless and had styles and stigmas of equal length. In the second generation there was

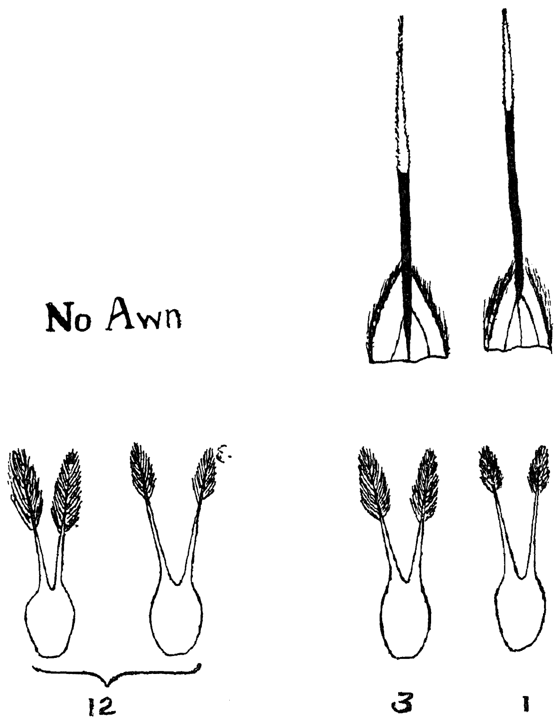


Fig. 2.

a segregation both for awn and for stigmatic distribution. Nil awn is dominant to long awn (Rangaswami Ayyangar, 1934).[3] In this cross equal distribution between stigmatic and stylar lengths proved a simple dominant to short stigma. The interest of the cross arises in the relationship between stigma and awns. The homology between stigmas and awns could not be pursued in the dominant awnless group which contained the two sets of stigmas. In the awned group also, there were both kinds of stigmas with this additional interest that being awned, equality and inequality of stigmatic surface kept parallel to the subular area of the awn (Fig. 2). A 12 : 3 : 1 ratio (actual figures 133, 33, 9) was obtained for the three groups, awnless, awned with equal lengths of subule and column and stigma

and style, and awned with unequal lengths of subule and column and stigma and style.

Diurnal Insects Attracted to Light.

OUR knowledge of the activities at night of diurnal insects is still meagre, but among the butterflies, the Hesperiidæ, Pieridæ and Satyridæ are already known to occur at night. It is, therefore, interesting to record here for the first time the attraction to powerful artificial light of the Lycænid, *Zizeeria otis otis* F., which Dr. Rao recently collected in Aberdeen, Port Blair, South Andamans.

In this case all the seven specimens (4 ♂s and 3 ♀s) were attracted, along with other insects, to the light of an 'Aida' kerosene stormproof lantern in the bungalow between 7 and 8 P.M. on a single night last July. The bungalow is about a furlong from the foreshore of the sea and 60 feet above sea-level. The brilliancy of the light of the lantern is 350 candle power. The vegetation surrounding the bungalow consists of grass and low herbage interspersed with a few trees. The weather was not unusual for the particular time of the year, and there was no strong breeze blowing at the time.

From the literature available it is evident that the Lycænidæ are exclusively diurnal and fond of sunshine.[1] Seitz[2] comments upon their peculiar habit in tropical countries of disappearing almost at once when the sky becomes overcast with clouds. He also remarks that he has never seen any coming to the light of a lantern at night. This may perhaps have been due to the low intensity of the light. The fondness of *Z. otis otis* F., for bright light, therefore, proves it to be positively heliophilous. *Zizeeria otis otis* F., is a small low-flying butterfly which frequents grass, being found commonly wherever it occurs. The species is recorded from North India, Burma, Andamans, and Car and Central Nicobars.

I am grateful to Dr. H. S. Rao, Assistant Superintendent, Zoological Survey of India, Calcutta, for his notes on the nature of the environment, the weather and time of occurrence.

On Two New Halcampactid Actiniaria from Madras Brackish Waters.

THE Actiniaria inhabiting the brackish waters of Madras include two new acontiated Athenaria[1] belonging to the family Halcampactidæ,[2] showing relationships to *Pelocœtes exul* Annand. and *Phytocœtes gangeticus* Annand., described by the late Dr. Annandale from the Chilka Lake and the Gangetic delta.[3,4] In a note, Dr. H. S. Rao[5] records the occurrence of some brackish water Actinians at Madras; but as no detailed study was made, he did not commit himself to any definite view about systematic position.

The two anemones differ from all the other known Halcampactids and they will be described elsewhere as two new forms. Both the Actinians have long vermiform and fairly differentiated columns, and physa-like bases without basilar muscles. They are burrowing forms found living in the shallow mud flats on the fringes of the Adyar backwater. The distinction of the mesenteries into microcnemes and macrocnemes is perfect in both cases.[6]

The first is a long pink anemone characterised by a curious atypical arrangement of the tentacles and acontia. Here the tentacular arrangement is a deviation from that observed in typical Actiniaria, caused by an interchange of the two final cycles accompanied by an undue development of the tentacles of the fourth cycle, which by their abnormal position assume a false exocœlic appearance. Contrary to what is observed in other Actiniaria, each macrocneme of this anemone bears a very large number of acontia and the latter show very peculiar variations in regard to their

attachment to the macrocnemes. An interesting correlation between the degree of development of the acontia and the probable order of succession of the macrocnemes has been observed as a result of the examination of a large number of specimens.

The second form is a beautiful, orange-striped anemone with black marks at the bases of the tentacles. It is easily distinguished by the nature of the oral disc, the very prominent throat ridges which surround the mouth taking an active part in feeding. The plan of arrangement of the tentacles and acontia of this anemone does not present differences from that observed for typical Actinians. The single acontium occurring on each macrocneme is a long thick structure, which is often shot out through the cinclides.

The two anemones have more or less similar anatomical features, the differences being mainly concerned with the finer details. The nature of the base and column, the plan of mesenterial arrangement and the distribution of the nematocysts are essentially the same, and clearly show their close relationships and position in the same family. In both cases, the nematocysts of the acontia include both penicilli and spirulæ.[7]

Like other brackish water anemones known from the east coast of India,[3,4] these are permanent inhabitants of the brackish water and show several adaptations in correlation to their peculiar environs. The occurrence of a large number of parasitic (or commensal?) Copepods in the cœlenteron of the specimens is noteworthy.

I wish to thank Professors R. Gopala Aiyar and T. A. Stephenson, for much valuable help and criticism.

Sexual Dimorphism in the Indian House-Gecko, *Hemidactylus flaviviridis*, Rüppel.

WITH reference to sexual dimorphism in *Hemidactylus flaviviridis*, Rüppel, Baini Parshad[1] says: "The male is much smaller than the female and is much more active and agile, in build also it is much slighter and can be easily distinguished even from a distance." Lydekker,[2] on the other hand, says that "among geckos the males are generally larger".

An examination of more than three hundred preserved specimens and actual observations on live individuals do not confirm any one of these statements. The size appears to depend not on sex, but almost entirely on age and on the amount of food obtained by the individual. Quite a number of males in my collection measure 6–6·3 inches from snout to end of the original tail, the distance from snout to vent being in many cases 3 inches or more. This compares well with the maximum size recorded by Boulenger[3] for this species, "from snout to vent 3 inches; tail 3·2 inches;" and with that mentioned by Malcolm A. Smith,[4] "from snout to vent 90; tail 90 mm." I have also got a great many mature female specimens of this species which are far short of the maximum size.

As for activity, I have not been able to make out any difference between the two sexes. The gravid females probably are just a little less agile than the males, but we cannot be sure of this distinction.

It appears that the only reliable method of sex identification externally is to look for the femoral pores (present only in the male[5]) and for the postanal bones and sacs. The latter structures, first mentioned by Noble[6] and later by Malcolm A. Smith,[7] are peculiar to Geckonidæ. "The sac is present in both sexes, but the bone only in the male."[8] In the female *Hemidactylus*, the postanal sacs are much smaller and open by minute slit-like apertures generally within the posterior lip of the vent. In the male they are quite prominent and have their outer rims more or less protruded owing to the presence of a curved bone inside. As Smith[9] points out, the bone "can be recognised, after a little experience, without dissection by inserting the point of a needle into the opening of the sac and lifting the bone upwards."

Besides the foregoing differences, I might also point out (I hope for the first time in

this genus) a peculiarity of the male assumed during the breeding season, and that is the presence of two swellings on the ventral aspect of the base of the tail, separated by a slight longitudinal depression. The female has this area either flat or slightly concave. This distinction becomes prominent in March or April and shows signs of disappearing towards the close of the breeding season.

As far as I can ascertain, the only record about such swellings is by Annandale.[10] He, however, mentions it in *Gymnodactylus* and appears to have noted only one swelling, probably owing to the two males that he examined having suffered from over-long preservation. I am in a position to confirm his statement that the difference (at least in *Hemidactylus*) becomes prominent during the breeding season.

The Quartzites of the Bababudan Area, Kadur District.

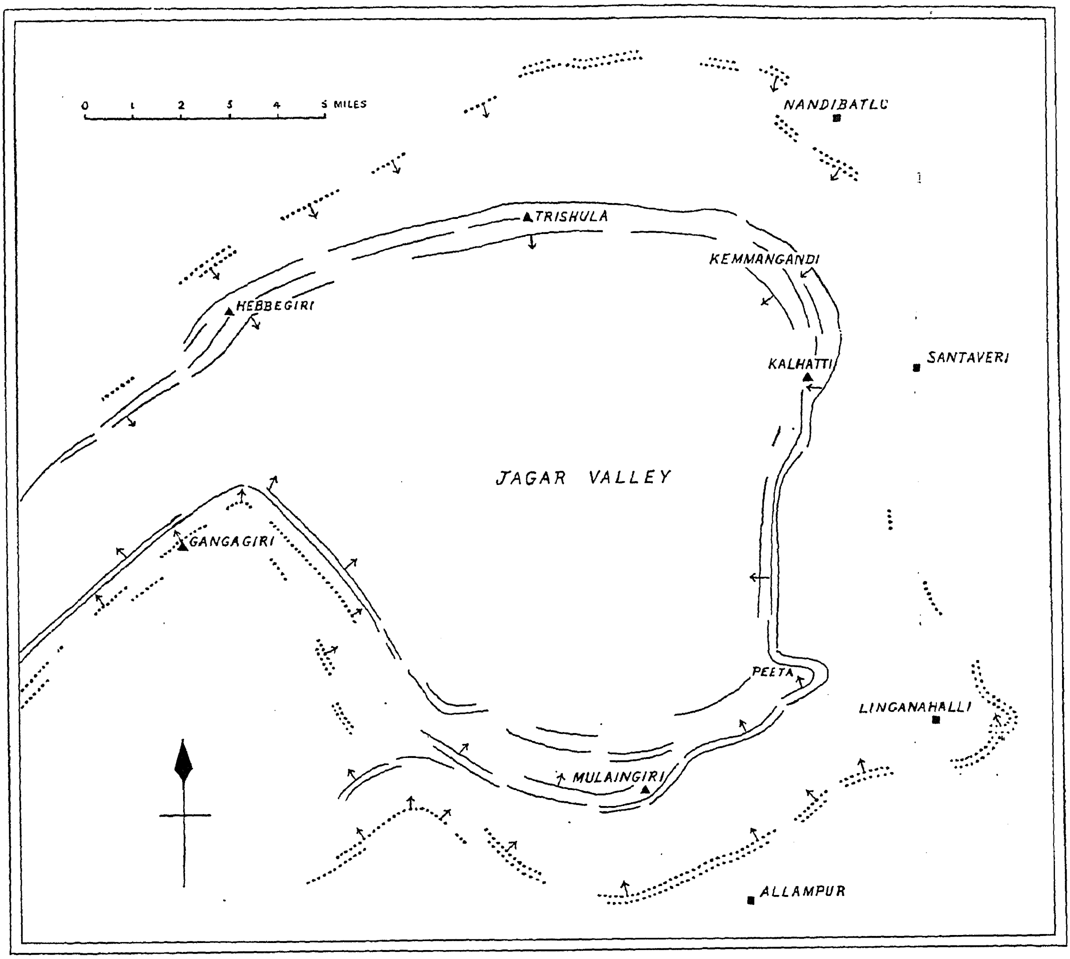
IN referring to the quartzites occurring in the Mysore State, Dr. W. F. Smeeth, one of the former Directors of the Mysore Geological Department, has stated : "There can be little doubt that many of the quartzites are crushed and recrystallised quartz-veins and quartz porphyries, and possibly felsites, and it is at least open to question whether we have any which are genuine sedimentary rocks."[1] In the course of a recent examination of the quartzites occurring in the neighbourhood of the Bababudan ranges, the writer obtained certain evidences which indicate that these quartzites are sedimentary rocks of the nature of sandstones.

The quartzites are generally white in colour, but often they are of various shades of brown. Sometimes they are green, this colour being due to the presence of a green mica. The texture is saccharoidal. The rocks are ordinarily compact but weathered specimens crumble into a granular sand. Under the microscope, the individual grains are often set off by the matrix which is sometimes ferruginous. The grains are not quite uniform in size. In highly crushed varieties, porphyroclasts of quartz occur in a matrix composed of minute grains of quartz, mica and iron ore.

There are several runs of quartzites in the area and brief descriptions of those occurring south of Allampur are given by Bruce Foote,[2] Sampat Iyengar[3] and Balaji Rao.[4] Sampat Iyengar considered that these quartzites were formed by the crushing of quartz reefs.

The runs of quartzite are remarkable in that they follow both in the directions of strike and dip, the banded ferruginous quartzites of the Bababudan ranges, which have been considered by the writer for reasons given elsewhere,[5] to be sedimentary deposits. Fig. 1 is a sketch map giving the main trend lines and directions of dip of the banded ferruginous quartzites, as well as those of the nearest quartzites. It will be seen from this map, that in spite of the discontinuity of the quartzite runs here and there, there is a general parallelism to the banded ferruginous quartzites which have a more or less ring-shaped outline. This agreement in trend is brought out very clearly by the bend in the quartzites near Linganahalli, which closely corresponds to the kink which is noticed in the ferruginous quartzites near the Peeta in the Bababudans.

The quartzites south of Allampur and immediately to the north of Chikmagalur are pebbly in character. The pebbles vary in size from a fraction of an inch to nearly



——— BANDED FERRUGINOUS QUARTZITE ·········· QUARTZITE

(Adapted from the map of Slater and Sampat Iyengar, *Recs. Mys. Geol. Dept.*, Vol. 9.)

Fig. 1.

Sketch map of the Bababudan area showing the parallelism in strike between the banded ferruginous quartzites and the adjoining quartzites. The arrows indicate directions of dip.

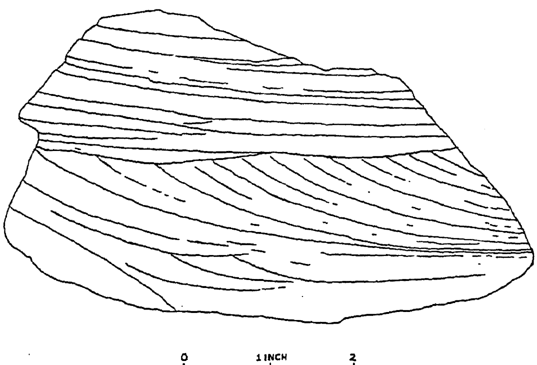


Fig. 2.

Sketch of a hand specimen of quartzite showing cross-bedding.

six inches across. Sampat Iyengar was of the opinion that these rocks were "pseudo-conglomerates," though he has admitted that the rounding of the quartz is so perfect that it could be very easily mistaken for a sandstone. In support of his view, he states: "Two or three of the rounded pebbles have undergone further crushing into smaller pieces so that, at present, the rock section (Z_3661) has assumed the form of a quartzite conglomerate. But the simultaneous extinction under the microscope of three or four rounded pebbles of quartz in close contiguity, give the clue to the crushed nature of the large pieces of quartz."[6] The writer fails to understand how, after pressure

had acted on the pebbles and *rounded* them, they could still preserve their original crystallographic orientation.

The most remarkable feature noticed by the writer in the quartzites is the occurrence of cross-bedding. Very good specimens were collected from the quartzites north of Allampur. Fig. 2 is a sketch of one of the specimens. The bedding planes are seen because of the deposition of ferruginous material along them.

The writer is of opinion that the facts of observation detailed in this note, definitely suggest that the quartzites of the Bababudan area are not of vein origin but are ordinary sedimentary arenaceous rocks.

Obituary.

Lieut.-Colonel H. W. Acton, C.I.E., I.M.S.

WITH the death of Lieut.-Colonel Hugh W. Acton, C.I.E., I.M.S., there terminates a very brilliant career of medical research work in India, and one of great benefit to this country.

Colonel Acton was a medical student of Middlesex Hospital, London, and before qualifying had carried out special research work on tumours under Sir John Bland Sutton. He entered the Indian Medical Service in 1907, and his first few years in India were spent in military duty,—chiefly on the north-west frontier. Here he made the important discovery that enteric fevers, which at that time were supposed to be of exceptional rarity among Indians, were actually not uncommon in Indian troops.

In 1910 he was posted to the Pasteur Institute of India, Kasauli, as Assistant Director under Lt.-Colonel W. F. Harvey, I.M.S. At that time antirabic treatment in India was in a rather unsatisfactory state. From 1900 to 1907 the Kasauli Institute had used Pasteur's original "dried cord" method, but this was unsatisfactory on account of sepsis and of the introduction into possibly susceptible persons of a large amount of nerve substance, which might lead to "neuroparalytic" accidents. From 1908 to 1911 the dilution method of Högyes was employed ; this was free from sepsis, and the amount of nerve substance injected was minimal, but theoretically at least, the use throughout the course of immunisation of a living rabies virus was not free from risk. Sir David Semple had suggested the use of a (dead) carbolised vaccine, and the years 1910 and 1911 at Kasauli were spent by Colonels Harvey and Acton in testing this out experimentally. Monkeys (*Silenus* or *Macacus rhesus* species) were used in very large numbers ; these had to be first inoculated with rabies "street virus" and then to be inoculated with the carbolised vaccine, and the experiments were carried out at very considerable personal risk to the workers concerned. The result of this work was the introduction in 1912 of Semple's carbolised vaccine, which is to-day in use throughout the Pasteur Institutes of India, and the present efficacy and smooth running of antirabic treatment throughout India is very largely due to the work of Colonels Harvey and Acton. Many years later Colonel Acton suggested the use of sheep instead of rabbits for the "fixed virus", thus again improving results. Whilst these experiments were in progress a "fixed virus" strain was established in the *Macacus rhesus* monkey and it was shown that the Negri body of rabies is of the nature of a cell-inclusion, this work anticipating by many years much of our present-day knowledge of the filterable viruses.

Between 1912 and 1914 Colonel Acton carried out other very important research work at Kasauli. This dealt with latent malaria in dog-bite patients, among whom the sudden change to the cold and altitude of a hill station may often precipitate a relapse of malaria ; with *Hæmoprojeus* infection in pigeons ; with the process of acclimatisation to a hill station altitude and a study of the blood changes concerned. Very important were his studies of snake bite in India. These occupied three years

and were carried out in a very systematic manner. Thousands of experimental animals were utilized—chiefly rats; and some three hundred or more poisonous snakes, the latter being caught by four gangs of professional snake catchers in the Bihar jungles. The chief results of this enquiry were to define with some approach to accuracy the doses injected by the different species of snakes concerned, the relative toxicity of the different venoms, the use of gold chloride as a neutralising reagent, and the necessity for a highly concentrated antivenene. A good resume of the whole subject is given by Colonel Acton in Vol. I of Byam and Archibald's *Practice of Medicine in the Tropics*.

After the outbreak of War in 1914, Colonel Acton was transferred to Simla, as Medical Officer of Health, and subsequently went to Mesopotamia as pathologist and surgical specialist to No. 12, Indian General Hospital at Amara. Here he studied especially the subject of oriental sore, and discovered that the distribution of oriental sores and of sandfly bites on the surface of the body is identical. An important memoir on the subject was published in 1919 and led to the incrimination of *Phlebotomus argentipes* as the vector in India of kala-azar, and of *P. papatasi* and *P. sergenti* as the vectors of oriental sore in north Africa, Palestine and Mesopotamia.

On his return from Mesopotamia, Colonel Acton was posted to the Malaria Convalescent Depôt at Dagshai. This afforded him a unique opportunity for research work on the treatment of malaria. British troops from the different war zones and from all over India were sent to Dagshai in the Simla hills to recuperate. The altitude and the absence of mosquitoes here excluded the possibilities of re-infection, and hence any attack of malaria which occurred was *ipso facto* one of relapse. In a short series of papers Colonel Acton and his colleagues at Dagshai showed: (*a*) that *Plasmodium vivax* is essentially the parasite associated with relapsing malaria; (*b*) that the alkaloids other than quinine in cinchona bark are almost, if not equally as efficacious in the treatment of malaria, so that the very much cheaper treatment with cinchona febrifuge may replace the more expensive quinine treatment; and (*c*) that administration of alkalies greatly enhances the value of the cinchona treatment of malaria. Later Colonel Acton proceeded on deputation to England, where he worked under Sir Henry Dale, at the National Institute for Medical Research at Hampstead on the action of the different cinchona alkaloids on free-living protozoa: the results of this enquiry were to confirm his previous work on the equal efficiency of the different cinchona alkaloids.

In 1921 Colonel Acton became Professor of Pathology, Bacteriology and Helminthology at the Calcutta School of Tropical Medicine, and held this appointment until April 1933. In this appointment he carried out a very large volume of medical research work of a very high order. His work on epidemic dropsy, for example, aroused widespread interest. He showed that the disease was almost always associated with the eating of diseased rice; that rice stored in damp godowns readily became infected with bacilli of the *vulgatus* group; this might cause the formation of soluble toxins in the rice, and when such rice was eaten the absorption of these toxins might cause the symptoms of epidemic dropsy. In very rare instances the patient might acquire an intestinal infection with these organisms, and his stools become infectious to other persons.

Other work, carried out in collaboration with Colonel Chopra, dealt with the toxins of the cholera vibrio;—a subject which is only to-day receiving the close attention which it deserves.

His work in collaboration with Dr. S. Sundar Rao on filariasis was a most notable contribution to tropical medicine. So many and varied are the manifestations of filariasis due to *Wuchereria bancrofti* that at one time the idea was raised that there might be more than one species of worm concerned in India. This view Acton and Sundar Rao showed to be wrong. In heavily endemic areas, such as the Malabar coast, transmission is possible practically the whole year round, the population is constantly being injected with large doses of developing filarial embryos, the superficial lymphatics readily become blocked, and, as a result, elephantiasis is the commonest manifestation of the disease. In slightly endemic areas, such as Calcutta, transmission is only possible for some three months or so of the year; the population receive only small and occasional doses of developing embryos; these are able to make their way rapidly to the deep lymphatics of the pelvis, and in such areas the chief manifestations of the disease are filarial fever,

lymphangitis, chylocele and hydrocele. The lymphatic glands may be blocked in one of two ways; either the worm may die in the gland and obstruct the flow of lymph; or it may cause irritation and inflammation of the gland as it passes through, and superadded sepsis from septic focus anywhere in the body may lead to acute inflammation. Thus the treatment of filariasis resolves itself into the careful examination of the patient for any source of focal sepsis which must be dealt with; the use of autogenous vaccines; and care of the general health. It is not likely that any drug will be discovered which, after injection, will reach the deep lymphatics of the pelvis where the mature worms are lying in sufficient concentration to kill them.

Other research work conducted by Colonel Acton at the Calcutta School of Tropical Medicine dealt with the dysenteries of India: in common with many other workers he found that the incidence of bacillary dysentery in the tropics is very much higher than that of amœbic dysentery. His outstanding contribution to tropical medicine, however, was his study of the skin diseases of the tropics. In 1921 when he commenced his special studies in this subject, it was one of very great confusion. The clinician was describing an ever-increasing variety of new syndromes under new names, whilst the pathologist was constantly discovering new fungi affecting the skin. The great merit of Colonel Acton's work in this subject was that he always searched for the true underlying ætiological agent. Thus a "weeping eczema" of the leg may be due to a streptococcal infection superimposed on a ringworm infection. The best line of treatment for such a condition is not to use irritants; but to use at first soothing applications; then perhaps an autogenous streptococcal vaccine to eliminate the streptococcal infection; then, when the secondary infection has been cleared up, the primary ringworm infection may be dealt with by more drastic remedies.

Colonel Acton's contributions to the subject of "tropical dermatology" were many, and all of them are of importance. He came to occupy almost the (honorary) post of consulting dermatologist to the whole of India. The numbers attending the clinic rose to 12,000 a year. Not only that, he also trained his assistants in methods and technique, and has left as a legacy to the School the only department of medical mycology in India.

Colonel Acton became Director of the Calcutta School of Tropical Medicine in July, 1928. In that appointment he showed not only his genius as a research worker, but his admirable capacity for directing and co-ordinating the work of others. He had an ability to get at the essentials of a research problem, to map out proposed lines of investigation, to suggest technique and procedure, and to assess results, characteristic of genius of a very high order. To-day there is not a department in the School which does not owe a deep debt of gratitude to his powers of organisation and administration.

India will long treasure his memory, for he was the most brilliant of a band of research workers in the Indian Medical Service which is rapidly dwindling in numbers. His life-work will serve as an example to the coming generation, for he gave his best to India with a selfless and devoted generosity.

R. KNOWLES.

Prof. Dr. Emmy Noether.

IN the death of Emmy Noether on 14th April 1935 as the result of an operation, the mathematical world loses one of the foremost investigators in the domain of modern Algebra and an unique and characteristic personality. She was born on 23rd March 1882 as the daughter of the mathematician Max. Noether.

Remarkable as her work was when due consideration is paid to her sex, it is still more remarkable as a contribution to the methods of mathematical thought which she employed in all her work. She was a great apostle of abstract thought and considered no theorem elegant and no proof complete until the inner abstract spirit underlying the ideas was laid bare. She never thought in terms of formulæ but only in concepts and therein lay her great strength. The guiding principle which she actually applied to her work was that no relations between numbers, functions and operations could be considered significant, capable of generalisation and useful unless they were detached from special environments and related to abstract conceptual notions.

It was in the domain of Algebra and Arithmetic that she worked most. She used and enriched the concepts of fields, ideals, modulus and isomorphism by a generalisation of Dedekinds "Modultheorie". Her doctorate dissertation (1907) concerned itself with Gordan's invariant theory in n-ary domain. She soon came under the spell of Hilbert's ideas and did fundamental work in connection with the finiteness theorem and the problem of construction of equations with specified groups.

Emmy Noether can truly be described as the greatest woman mathematician who has done work of such high excellence in the region of abstract mathematical thought.

B. S. M.

Magneto-Chemistry.*

In recent years there has been a great revival of interest in magneto-chemistry, and an extensive series of experimental investigations have been carried out, stimulated by the fact that there is now a sufficient background of adequate theory to enable the significance of the results obtained to be more clearly appreciated. One of the most active workers in the field has been Prof. Bhatnagar, who, with his collaborators at Lahore, has contributed extensively to the progress that has been made.

Although a number of good books have been written on various aspects of magnetism in the last few years, none has been written by a chemist. In the study of the more complex compounds, whether inorganic or organic, a thorough knowledge of the chemical outlook on questions of constitution is necessary in order that the salient points of interest in the results may be brought to light. Prof. Bhatnagar is well fitted to deal with such questions. Further he can approach the general treatment of magnetism with a due appreciation of the kind of presentation which will be of most value to chemists who previously have not studied the more physical and mathematical aspects of the subject. The aim of this book is to place before chemists a comprehensive and at the same time comprehensible account of the experimental and theoretical researches which have been carried out in this field. The authors have been extremely successful in achieving this aim.

Of necessity, if the book was to be a more or less complete whole rather than a chemical supplement, previous books have been freely drawn upon, as is fully and gracefully acknowledged. It is unnecessary to review in detail such parts of the book as present anew such matters as have been dealt with elsewhere. It is sufficient to say that the matter has been well selected, and that in the presentation further points of cognate interest are often noticed, and that where necessary more complete tables of data are given. In indicating the scope of the book, special attention will be directed to those parts which deal more particularly with matters which have not previously been dealt with in detail in book form.

* " Physical Principles and Applications of Magneto-Chemistry." By S. S. Bhatnagar and K. N. Mathur. Pp. xiv + 375. (Macmillan & Co., London, 1935.)

The book opens with a pleasantly written historical introduction, in which mention is made of a reference to the lodestone in the Vedas, and, to skip over intervening millenniums, an appreciative account is given of such earlier theories of magnetism as those of Poisson, Weber and Ewing. The fundamental ideas and definitions are introduced, and an account is given of the usual methods of producing magnetic fields, the large Paris electro-magnet being also described. A brief account of methods of measuring fields follows, particular attention being paid to the convenient fluxmeter method. The theory of susceptibility measurements is given in a sound, if not quite the simplest, form, and a very full account follows of the various types of magnetic balance, including several which are due to Bhatnagar and his pupils. This is probably the fullest account of magnetic balances which has been given, and will provide the intending investigator with a wide choice.

The work of Curie, Honda and Owen, and Pascal is then described under the heading "Pan-Magnetism of Matter". The account of Pascal's work, which, it seems to the reviewer, is seldom sufficiently appreciated, is very detailed and contains a most valuable set of tables of data.

An account is then given of the theory of spectra and atomic structure, based on the original Bohr theory, and the vector model of the atom. It is wise of the authors not to overload their book by entering more fully into the intricacies of quantum mechanics, for the account given here will probably be quite adequate for the chemical experimentalist.

Dia- and para-magnetism are treated in turn : an adequate indication is given of the quantum-mechanical treatment of Van Vleck, and also of the theory of the paramagnetism of free electrons. The account of ferromagnetism is very brief, but it is sufficient to draw attention to the complexities of the problems involved, which fall rather outside the central chemical field.

Magnetism and valency are then considered, the sequence of ideas due to Werner, Kossel, Lewis, Heitler and London, Sidgwick and Pauling being traced. Ionic paramagnetism is taken up again, and here there is some overlapping, but it is not serious, as the questions are discussed from

new points of view, and complex compounds are also considered.

In a chapter on magneto-optics, the Faraday, Cotton-Mouton, Kerr and photomagnetic effects are discussed. Here of particular value is the detailed account given of the magneto optical researches of Perkin, which parallel those of Pascal, and have been too often overlooked.

A summarizing account of the various magneto-mechanical and galvano-magnetic effects occupies the twelfth chapter, which is followed by a chapter on magneto-crystallic action, which is brought well up-to-date. The interesting question of the influence of magnetic fields on chemical reactions is then discussed, and in the final chapter some miscellaneous applications of the use of magnetic properties in physico-chemical investigations are described.

In an epilogue attention is directed to some outstanding problems, such as those connected with the magnetic properties of compounds of transition elements other than those of the iron and rare earth group and the interpretation of the significance of the Pascal constitutive factors, and to the need for more precise measurements of a large number of substances. An appendix includes a useful list of susceptibility values.

It will be clear that the book covers the field in an extremely comprehensive manner. It will be readily comprehensible, and the extensive information it gives, the numerous tables of data, and the lists of references will undoubtedly be of great value, particularly to chemists, not only in showing what has been done, but also in indicating lines of investigation which should be followed up. Prof. Bhatnagar and Dr. Mathur are to be congratulated on having brought to completion so successfully a book which clearly entailed an enormous amount of painstaking work, and so making available to others a detailed survey of the investigations which have been carried out in this wide field.

It remains to add that the book is well-indexed and excellently produced. It is a most useful addition to the literature of magnetism.

EDMOND C. STONER.

The Structure of Molecules.*

THE latest volume of the collection of works on modern molecular physics, which was edited by Born and Franck, is a book of Dr. H. A. Stuart: *Molekülstruktur*. Like all the other volumes of this series it is meant primarily for the research worker, interested in similar lines. Although a brief account of the wave-mechanical theory of valency and band spectroscopical determinations of the energy of dissociation have been given in the first and last chapters, the main interest of the monograph is not concerned with the electronic configurations of the molecules, but centres round the questions of the arrangements of the nuclei. Here, however, in a branch of knowledge to which the author has contributed to a large extent, particularly by measurements of the Kerr effect, the publication is an extremely reliable and useful guide. In the second chapter the older methods to determine the constants of a molecule are described, such as arise from kinetic theory. A chapter on direct measurements of internuclear distances and valency angles by X-ray spectra and electron interferences, is followed up by a more theoretical presentation on the inner-molecular potential, free rotation and related questions.

The three following chapters particularly will interest most of the readers. The first of them deals with electric polarisation and dipole moment of the molecules and with the structure of the molecules as revealed by the approximately constant moments of the groups. Then follows a chapter on the depolarisation of Tyndall and Raman radiations and the electric Kerr effect which is particularly valuable in determining the anisotropy of the polarisability of a molecule and finally a chapter on infra-red and Raman spectra, by which the vibration frequencies of the nuclei are determined.

In order to see, how these different methods to determine the nuclear structure of a molecule supplement each other, we will consider the results obtained for nitrous oxide, the structure and formula of which were uncertain for a long time. The mere existence of the Raman spectrum excludes from the beginning any electrovalent formula. The Kerr effect excludes a formula

* *Molekülstruktur*, by H. A. Stuart (Verlag von Julius Springer). Pp. 388. Price RM. 33·80.

like  and, since the dipole moment is small but certainly different from 0, a symmetrical formula like N—O—N is not possible. Indeed, infra-red and Raman spectra are in best agreement with the unsymmetric linear formula $N \equiv N = O$, which is confirmed by experiments on electronic interference in N_2O which also indicate a distance of 2·38 A.U. between O and the farther N atom.

This one example may be sufficient to show that it is rarely possible to determine the structure of a molecule by only one experimental method, which describes and seizes only one of its properties, but that all of them have to be taken into account. Dr. Stuart's monograph will be extremely useful to all those who want to compare their own results with those obtained by others by different methods.

R. SAMUEL.

Electro-kinetic Phenomena.*

THE Board of Editors of "The American Chemical Society Monographs" has two objects in view in publishing their excellent series: first, to present the knowledge available upon a chosen topic in a readable form, intelligible to those whose activities may be along a wholly different line and secondly, to promote research in the branch of science covered by the monograph, by furnishing a well-digested survey of the progress already achieved in that field and by indicating fruitful lines along which the investigation might be extended. That both these commendable objects have been achieved in a special degree will be realised by every reader of the monograph on Electrokinetic Phenomena, which presents for the first time important literature scattered through various journals in a connected form.

The phenomenon has been treated from a definitely biological standpoint. The volume includes discussions on organic compounds, blood cells, soils and inorganic materials, and a separate chapter has been devoted to the special aspects of electrokinetic phenomena relating to proteins. Problems connected with the fractionation of proteins from their mixtures are indicated in the section on mixtures of proteins. The applications of this phenomenon in the field of biology and medicine are indicated particularly in the Chapters X and XI which deal with blood-cells, tissues, spermatozoa, bacteria, antibodies, viruses, etc. The selective permeability of living membranes in relation to the electrostatic forces obtaining in the pores of the membrane, which is discussed in the volume, has a close bearing on the introduction, locally, of drugs, the molecules of which are charged.

The fact that isospermatoxins produce loss of sperm motility, leads to the possibility of determining quantitatively the period of immunisation against pregnancy. The influence of such precise physico-chemical control of contraceptive technique should be of more than usual significance. The above two examples of the application of the electrokinetic phenomena, culled out at random from the book, is illustrative of the wide appeal which the volume is entitled to have. The book is written in a style and manner which render it not only exceedingly informative but also most stimulating.

Chronica Botanica.*

FR. VERDOORN has done a great service to the Science of Botany in bringing out *Chronica Botanica*, a useful book of 447 pages. This is mainly a book of information on the progress of Botany in all its aspects pure as well as applied and the author wants to publish it every year. Its success will depend upon the co-operation of the Botanists all over the world.

The book opens with a letter from E. D. Merrill of the New York Botanical Gardens. There is a timely pleading for the International Co-operation among the Botanists. When the spirit of narrow nationalism is running so high it is very gratifying to read this letter. International co-operation has been successfully achieved by Botanists. The plants have no narrow political boundaries. The real co-operation began with the Taxonomists.

In the Almanac for the year 1935 useful information is given of outstanding anniversaries, meetings of International Congresses and Jubilees of various Botanical Institutions.

The detailed programme of the Sixth International Botanical Congress in Amsterdam, 1935, and its Officers occupies nearly ten pages. In the middle of this, a page is set apart for the portraits of eminent Botanists who passed away since the fifth Congress. It is curious that D. H. Scott, the premier paleobotanist, does not find a place here. A special note has been added about John Briquet (1870–1931), a great Taxonomist who rendered invaluable service to Taxonomy and to the success of the International Botanical Congress.

A lucidly written article by A. B. Rendle, F.R.S., on the history of the International Botanical Congress from 1864 to the end of 1930, when the Congress met in Cambridge is of great value for all students of Botany. He shows how the earlier congresses had combined both Horticulture and pure Botany for discussion. From 1900, when the Congress met at Paris the pure Science is having a separate Congress. The second and third Congresses were held in Vienna (1905) and Brussels (1910). Owing to the great catastrophe of 1914–18 the Congress could not meet in London in 1915 and the aftermath of this lasted till 1926 when the Congress met at Ithaca, New York. The 1930 session at Cambridge with Prof. A. C. Seward as President, was a great success and it may be said that the Congress has become a normal annual event.

This is followed by accounts of various International Congresses, Committees and Societies. Useful information for those that are engaged in special fields could be gathered from these. Unfortunately no mention has been made of the Indian Science Congress here.

The succeeding chapter on a Review of all branches of Plant Science during 1934 which occupies the bulk of this publication covers 258 pages. The progress of the Science and personal news are treated in all countries in the alphabetical order, commencing from Afghanistan and ending with Zanzibar. The accounts of persons and matters are of real value. In spite of the earnest appeal from the author, the response has not been adequate. While the technical departments have given useful accounts of the institutions, the Universities have not manifested their co-operation. In India seven out of the seventeen Universities have sent meagre information. It is necessary that all the institutions should send as far as possible a fuller account of their equipment and the investigations carried on or are in progress.

This annual register does not seem to be the proper place for correspondence, however useful the letters may be.

The last 103 pages cover the new and changed addresses of persons, classified advertisements of posts, book-sellers and periodicals. Even the laboratory suppliers find their place here.

A short illustrated History of Botany in the Netherlands has its humourous side.

The book should find a place in every Botanical Institution.

M. A. SAMPATHKUMARAN.

* *Chronica Botanica*, edited by Fr. Verdoorn, Leiden Netherlands, 1935, pp. 447, 15 Neterl. guilders.

Reptilia and Amphibia of British India.*

THE present volume is the second of the four into which Dr. Smith planned to divide the revision of the Reptilian and Amphibian Fauna of British India. The first volume, dealing with the *Loricata* (Crocodilia) and *Testudines* (Chelonia), appeared in March, 1931. The third volume will deal with the Snakes, and the fourth with the Amphibians. Both the volumes so far published mark a decided improvement over Boulenger's work "Reptilia and Batrachia" 1890, in this series.

As mentioned by the author in his preface to the First Volume, the region dealt with is not precisely that forming the scope of Boulenger's work, but "has been extended to include the whole of the Indo-Chinese sub-region, and is almost the same area as that included by Günther in his "Reptiles of British India," 1864. This extension in the limits of the area dealt with is due to the fact that the fauna of Siam, French Indo-China and Southern China is so closely allied to that of Burma that the author feels it to be scientifically incorrect to separate the two from each other. We trust that the change is for the better, as it makes it possible to avoid the artificial division of this natural sub-region and to consider it as a *whole*. Altogether, the volume on *Sauria* (Lizards) describes 297 species, of which 248 occur in the Indian Empire; while Boulenger's work (1890) contained descriptions of 226 species of Lizards (including also the Chamæleon), of which 17 were "included upon incorrect data or have since been placed as synonyms". This means that Dr. Smith's volume contains the descriptions of 39 more species than Boulenger's.

As in his descriptions of the orders *Loricata* and *Testudines* in the First Volume, the author begins his work on *Sauria* with an illuminating general Introduction, which deals with Structure, Evolution, Devolution, Geographical Distribution, Economics, and Preservation and Examination of Specimens. Dr. Smith possesses the knack of clear and concise expression and he has, in this Introduction, condensed a great deal of scientific knowledge about this group of reptiles. In the section on Evolution and Devolution, he gives a valuable account of the evolution of the adhesive digital pad and the external coverings of the eye, as also of the degeneration of the eye, the ear and the limbs. The remarks in this section, as pointed out in the preface, are the "outcome of the study of the structure of the Indian and Indo-Chinese species". But the author assures us (pp. v, vi) that he has carried out his researches much further afield and has studied the whole group from this standpoint. We look forward eagerly to a fuller account of these problems.

About *femoral glands or organs* (p. 4), the author says, "They are not true glands, but tubular invaginations of the epithelium, the opening of which, termed the pore, may perforate a scale or lie between two or more scales." We are not in a position either to endorse or to refute the author's verdict that these are not really glands; but certainly there are a great many workers who have investigated these structures and are inclined to regard them as glands. Camp (1923)[1] gives an excellent résumé of the work done in this direction, and says: "Duvernoy, Wagler (1830),[2] and Johannes Muller first noted the glandular nature of the femoral organs. The histology has been investigated by Leydig (1872), Schæfer (1902),[3] Cohn (1904),[4] Tölg (1903),[5] Félizet (1911)[6] and others. Félizet remarks upon the similarities with the mammalian sebaceous gland....... This was also partly the view of Meissner (1832),[7] Leydig, and Schæfer, and many later workers....... Maurer....believed that the proximity of lymph spaces indicated a similarity to the musk glands of crocodiles..... The glands

[7] Meissner, C. F., "Die Amphiborum quorandum Papillis Glandulisque Femoralibus," 1832, Basel.

are seemingly of functional significance and not vestigial or rudimentary structures."

As regards the evolution of the *external coverings of the eye* (p. 9), the author believes that "the simplest form of eye-covering is to be found in the Geckoes" and that this type has given rise to others by "the disappearance of the immovable transparent disc, its function as a covering for the eye being now undertaken by the eyelids. Whether it becomes thinned and so disappears, or whether it becomes united with the cornea," he is "unable to say". May we point out that some zoologists (*e.g.*, Johnson, 1927),[8] who have given thought to this problem, regard the gecko type of eye-covering as not simple, but specialised, due to an "excessive development and specialisation of the nictitans, which becomes quite transparent"?

Besides the Introduction, the volume on *Sauria* contains excellent systematic descriptions of the sub-order, families, genera and species of the region dealt with; complete synonymies of not only the generic and specific names, but also of those of the families and the sub-order; a glossary and general index; and a fairly complete bibliography. The author has examined the types of almost all the species mentioned and has taken great pains to make the work as authoritative and helpful as possible. He has followed the law of priority in nomenclature rather rigidly, and has carried it "into all groups, although the Rules of Zoological Nomenclature do not, at present, require it to be carried higher than genera". For our part, we doubt the utility of changing the nomenclature of zoological classification at the cost of common usage, especially in the case of groups higher than genera and species.

In going through the Bibliography, one observes the omission of several important papers, referred to in the text. One looks in vain, for example, for the papers of Weekes, 1929 and 1930 (referred to on p. 6 of the volume), Hingston, 1933 (the same page), Hewitt, 1929 (referred to on p. 3), etc. Much of the value of a work like the present one lies in directing our attention to the original contributions on the subject and we hope that Dr. Smith would give a more complete list of references in the coming volumes on Snakes and Amphibians.

Boulenger (1890) in his volume on "Reptilio and Banrachio" preferred to divide Lizards into two sub-orders: *Lacertilia* and *Rhiptoglossa*, the latter consisting of a single family, *Chamæleotidæ*. Dr. Smith, however, includes *Chamæleotidæ* along with the other Indian families of Lizards in the same synopsis (pp. 20–21) and places this family just after *Agamidæ*. This is in accordance with Cope's opinion that the Chamæleons are related to the Agamids, an opinion confirmed by Camp (1923).[9]

One might mention, perhaps, that in the case of one genus at least (*Hemidactylus*) no mention of the size and nature of eggs is made even though we have some records about them. Baini Parshad's article on *H. flaviviridis* (*Jour. Bom. Nat. Hist. Soc.*, 1916, **24**, pp. 834–838) has, apparently, not been available. It would probably be better also to have the glossary of each volume as complete as possible, irrespective of the fact that some terms have been explained in a previous volume. Such a procedure would make each volume of this series so independent of others as to make reference by a layman really easy and would facilitate his understanding of the common terms used in the text to a considerable extent.

Dr. Smith is a well-known herpetologist, and we are sure that his present work is really the best introduction so far published to the systematic study of Indian Lizards. He has produced a volume of decidedly high order, and Indian zoologists should be particularly grateful to him for it.

Research on Lac in Great Britain.

IT is two years since the Indian Lac Cess Committee deputed three research workers to England to carry out a scheme of research in the industrial uses of lac, in the fields of the paints and varnishes, the plastics and the electrical industries. In the preface to the first technical paper, Dr. Jordan refers to the several lines of investigation being pursued concurrently and the first bulletin deals with the isolation of the Pure Lac Resin, the economics of whose isolation and utilisation must, for the moment, remain an unsettled question. The paper by Dr. Bhattacharya and Dr. Verman on this subject of isolation of pure resin is a very valuable contribution which promises to find application in technological development of lac. Dr. Verman has discussed the industrial possibilities of pure lac resin, in a paper read at a joint meeting of the London section of the Plastics Group. The most hopeful application of the lac resin, which Dr. Verman has indicated, is in the manufacture of an insulating varnish for wire, which should be able to withstand elevated temperatures for long periods of time. The pure resin has a quicker rate of hardening than the original lac and this circumstance should extend the employment of the pure lac resin to regions where the "slow hardening" of untreated lac has been found defective. Another application of great promise is the manufacture of canning aluminium and tin foil lacquers. Experiments have shown that with pure lac resin, can be successfully made coloured lacquers, having good adhesion and non-sticky. Yet another possibility which Dr. Verman has indicated is the employment of the pure resin for electric insulating moulding. The chief difficulty in shellac moulding at the moment is the slow rate of heat-hardening and any process through which the time of hardening could be reduced, will be considered a useful technological development. Properties of the pure lac resin in this respect have not been investigated except to show that it possesses a quicker rate of hardening than shellac; with the addition of accelerators it may be possible to reduce further the time of hardening and in this direction we shall await with keen interest the results of Drs. Bhattacharya and Verman.

One pauses to reflect if all this work detailed above could not have been done in India at the Lac Research Institute at Ranchi or at the Indian Institute of Science, Bangalore. It is true both these Institutes have to a large extent pioneered researches on the various aspects of lac but what has been sadly lacking with respect to both of them is that close contact with the consuming industries, which have always been responsible for stimulating applied research. The Indian research workers who have now been stationed at the Paint Research Station at Teddington, have the enviable opportunity of facing the practical problems of the industry understanding their needs and meeting their exacting requirements through research. They have done well indeed but the Indian Lac Industry expects more work from them, if it should escape the crisis.

Alchemy in China.

IN an interesting article appearing in *Nature* (1935, **136**, 287-88), Prof. J. R. Partington gives an accouut of an ancient Chinese Treatise on Alchemy, an obscure and mystic work of considerable historic importance. The treatise is *Ts'an T'ung Ch'i* of Wei Po Yang who flourished in the 2nd century A.D., and was called the 'father of Chinese alchemy'. This treatise has been recently translated by Dr. Lu Ch'iang Wu and annotated by Prof. Tenny L. Davies. The translation is a task of no small difficulty from which, the previous sinologists had turned away in despair. The treatise has been considered to be the earliest, in Chinese language. From the references to earlier Chinese alchemists it is reasonable to assume that for at least 2 or 3 centuries before Wei Po Yang, attempts to transmute base metals into gold and prepare elixirs of life were being made and alchemy in China and Greece was contemporary. "Dr. Wu and Prof. Davies are to publish later some alchemical chapters from Ko Hung, a celebrated Chinese Taoist Philosopher and Alchemist of the fourth century and the history of chemistry will be enriched by their work."

Research Notes.

Variation of the Mass of an Electron with its Velocity.

As is well known there are two theories of the electron leading to different expressions for the dependence of the mass on the velocity, namely the theories of Abraham and of Lorentz, the result of the latter agreeing with that of the Relativity Theory. Bucherer's experiments are taken to provide evidence for the correctness of the theory of Lorentz as against that of Abraham, but the accuracy of the experiments is not sufficient to accept them as conclusive. Sommerfeld's theory of the fine structure of hydrogen lines provides an indirect proof of the correctness of the Lorentz formula. However, a direct experimental proof was a desideratum and one is now provided by the experiments of M. Nacken described in *Annalen der Physik*, 1935, **23**, 313. Nacken has used cathode ray electrons accelerated through 200 kilovolts and 7 kilovolts respectively so that there was an advantage over using the β-rays from various sources in that the intensity of the beam could be increased and sharper lines could be obtained with shorter exposures. The cathode rays are deflected by electric and magnetic fields: there is however an improvement in that the electrons of 7 kv. and 200 kv. are made to trace the same path by adjusting the strengths of the electric and magnetic fields so that errors due to the geometry of the apparatus do not appear in the calculations. If J and J′ are the currents in the magnetic field-coils and V and V′ the potentials between the condenser plates required to produce the same deflection in the 200 kv. and 7 kv. electrons respectively and $\beta = 0 \cdot 161 \dfrac{V/V'}{J/J'}$ then if μ and μ_0 are the masses of the two groups of electrons, $\dfrac{\mu}{\mu_0} \dfrac{\beta}{J/J'}$ = a constant = 0·166 according to Lorentz's theory but slightly variable and equal to 0·154, 0·153, 0·153, 0·152 and 0·150 under the experimental conditions used by Nacken. The actual values obtained for this quantity were 0·166, 0·165, 0·164, and 0·162 with a mean of 0·164 while the error in determining J/J′ might be 0·7% and that in V/V′ could be 0·6%. Since the results to be expected according to Abraham's theory differ from the experimental values by 6·1 %, 7% and 8·5% while the deviation of the mean result from Lorentz's theory is only 1·2%, Nacken concludes that his results decide definitely in favour of the theory of Lorentz.

T. S. S.

The Velocity of Light in a Partial Vacuum.

THE late A. A. Michelson had made arrangements to determine the velocity of light in vacuum but his death prevented his concluding the work. F. G. Pease and F. Pearson who were associated with him in this work have carried it on to a successful conclusion and an account of the results so far obtained is given in *Astrophysical Journal*, 1935, **82**, 26. The method used was that of the rotating mirror having 8 and 16 faces and the light travelled to and fro inside a steel pipe line, one mile long and evacuated to a pressure varying from 0·5 mm. to 5·5 mm. of mercury. The details of this stupendous undertaking are illustrated by beautiful photographs. The light-path used varied from 8 to 10 miles. The distance was accurately measured by comparison with a carefully measured base-line set up near the pipe line. The number of revolutions per second made by the mirror was correctly determined by strobscopic observation of a tuning fork synchronised with the rotating mirror, the tuning fork being compared with a freely swinging pendulum which was compared with a chronometer which in its turn was rated by means of time signals from Arlington. "2885·5" determinations of the velocity were made during a number of years and the mean value obtained for the velocity of light was 299774 km. per sec., the average deviation from the mean being 11 km./sec. As Birge has pointed out (*Nature*, 1934, **134**, 771), this result agrees with the values obtained by Mittelstædt (1928), Mercier (1923) and Rosa and Dorsey (1906) using other methods, and so the variation of the velocity of light postulated by Gheury de Bray and Edmondson may be only apparently confirmed by the measurements employing long base-lines.

T. S. S.

Photo-Oxidation in Near Infra-Red.

IN the photo-oxidation of organic substances in presence of chlorophyl, under favourable conditions one molecule of oxygen is absorbed per quantum of absorbed light, irrespective of the wavelength. If the

wavelength of the incident light is continuously increased, for any given substance, there will be a limit beyond which the absorbed quantum will be insufficient for the activation energy required for oxidation. This, in principle, simple method for determining the activation energy for autoxidation of organic substances, however, requires a dyestuff which absorbs in the red and infra-red, and also a filter that transmits in these regions. Chlorophyl is not suited for this purpose as it does not absorb even in the visible red region. H. Gaffron (*Berichte*, 1935, **68**, 1409) has discovered in Bakterio-chlorophyl (extracted from *thiocystis*) a suitable dyestuff for this purpose. A solution of this in acetone, containing thiosinamine as acceptor absorbs oxygen when irradiated with light even beyond 760 $\mu\mu$. This observation settles that it is not the oxygen that is activated by the sensitised dyestuff—as has been postulated by some, —since the energy required for the activation of oxygen to $^1\Sigma$ state is 37000 cal. corresponding to 762 $\mu\mu$, and thus light of longer wavelength would be ineffective.

M. A. G.

Inter-Molecular Forces in the Liquid State.

P. GIRARD AND P. ABADIE (*J. de Physique*, 1935, **7**, 295) have reported an interesting observation that the time of relaxation of a polar molecule in the liquid state, is extremely sensitive to the inter-molecular forces. Although Debye's theory of dispersion of dielectric constants is not strictly applicable to the pure liquid state, from the observed dispersion data, the characteristic period of relaxation τ can be evaluated by choosing a proper value for a in $\tau = \frac{4\pi\eta a^3}{T}$, where η is the viscosity of the liquid, T the absolute temperature and a is a constant having the dimension of molecular radius. This value of a gives a direct measure of τ after allowing for the influence of η and T. A comparison of the values of a shows, contrary to expectation, that the time of relaxation for different polar molecules in the liquid state varies *inversely* as the polarity of the molecule. By a process of elimination, it has been deduced that this remarkable relation must be attributed to the inter-dipolar forces prevailing in the liquid state. This is confirmed by the observation that when the polar liquids are diluted by non-polar solvents, the relaxation time increases to a maximum value of 3 to 7 times the original value, and then decreases. The nature of this curve would seem to indicate that the inter-molecular forces can have both effects, *viz.*, to increase or to decrease the time of relaxation according to conditions. It is briefly indicated that such effects can be attributed to the structure of the liquid state resembling more closely the crystalline state than the gaseous one.

M. A. G.

The Range of Action of Surface Forces.

BASTOW AND BOWDEN (*Proc. Roy. Soc.* (A), 1935, **151**, 220) have made viscosity measurements of thin liquid films, which throw light on the state of the liquid molecules in the neighbourhood of a solid surface. The results show that the solution of a liquid crystal has pronounced rigidity ; but no such effect is observed with normal liquids such as water, alcohol, acetic acid, etc., even in the neighbourhood of the freezing point. Furthermore, acetic acid shows a normal behaviour while it is in the supercooled state —a state in which there is comparatively high probability for the formation of the multimolecular layers. The results negate the conclusion of certain workers that there could be induced rigid structures of molecules extending from a surface to a distance of 1500 Å to 50000 Å. The length of such oriented structures, if they exist, is certainly less than 1000 Å and probably very much less.

K. S. G. D.

The Influence of the Electrode Surface on Anodic Reactions.

THE mechanism of the anodic oxidation of compounds at different electrode surfaces is of considerable practical and theoretical significance. Glasstone and Hickling (*J.C.S.*, 1934, 1878) have recently advanced the view that hydrogen peroxide is formed as a primary reaction product on the surface of the anode. This has been seriously questioned by Walker and Weiss in a recent paper (*Trans. Far. Soc.*, 1935, **31**, 1011). They have adduced definite evidence to the non-formation of hydrogen peroxide. The formation of oxide films which change the nature of the anode surface has however been detected. From the standpoint of quantum mechanics, there is a potential barrier between the electrode and the reacting

ions round it, which are in an adsorbed condition. It has been shown that for the discharge of an anion at the anode, the following relation should be satisfied.

$$\phi + V_a > E_{ion} + H_{ion} - \Delta A$$

where ϕ is the work function of the metal electrode, V_a the applied anode potential, E_{ion} the electron affinity of the adsorbed anion, H_{ion} the hydration energy of the anion and ΔA the adsorption energy of the process. In the above relation, both ϕ and ΔA depend upon the properties of the surface. Anodes with high Oxygen over-voltage (*e.g.*, Smooth platinum) favour the primary deposition of the anion, since the electron affinity of other anions is lower than OH^-. In the case of electrodes with low over-voltage (platinised platinum, metallic oxides), the primary discharge of the hydroxyl radicle may take part in the chemical oxidations on the anode.

M. P. V.

Study of Evaporation of Water from a Soil Surface.

THE dependence of fluctuations of water table on the surface evaporation and atmospheric pressure was investigated by Vaidhianathan and Luthra (*Research Publication*, November 1934, **5**, No. 3, Punjab Irrigation Res. Inst.) at Lahore during June, the hottest part of the year. Surface evaporation was studied for 11 days by exposing P_2O_5 in shallow bottles kept under a bell jar, while the fluctuation of water-table was studied by means of observation pipes fitted with strainers. It was found that while pressure has an effect on the fluctuation of the level of the water table, when the surface evaporation is high, however, the fluctuations of water table and pressure became out of phase and evaporation became the most predominating factor. The conclusions of the previous workers made in Australia and elsewhere that pressure is the main factor effecting the water table do not apply to the conditions existing in Lahore. It was found that there is continuity in the moisture content of the soil between the water table and the surface even though the water table is at a depth of 22 feet below the surface indicating that the water lost by evaporation is being continually replenished from the ground water level. This is in contradiction to Keen's observations made at Rothamsted that water which receded 6 ft. is not drawn up by surface evaporation. The amount of water evaporating from the surface was found to be $2 \cdot 7 \times 10^{-7}$grs. per sq. cm. per sec. on the average for June, when the maximum temperature was 66° C.

A Statistical Examination of the Uplift Pressure Data obtained from Model Experiments.

A NUMERICAL estimate has been made of the "Experimental Error" involved in the data obtained from model experiments to determine uplift pressures by Malhotra and Uppal (*Research Publication*, Jan. 1935, **1**, No. 5, Punjab Irrigation Res. Inst.). Attention was confined to the variations of "percentage drop of pressure" at individual pipes, the observations being taken from the same model though the head was varied. 97 individual pipes were used for each set of observations and they have been classified into 6 groups depending upon the experimental conditions. Eliminations due to choking and other causes have been made of some individual pipes. The analysis of variance due to Fisher was applied to the figures for "percentage drop of pressure". It was found (i) "that the upper limit of the 'Experimental Error' for any group of observations is less than 0·50" and (ii) that "all but about 1 per cent. of the observations would fit into a range of 3E on either side of the mean value for the pipe"; (iii) "In only one case 3E was as high as 1·5 and in all other cases it is less than 1·0"; and (iv) "An increase in the dimensions of the model did not affect the magnitude of the error."

Oil Formation in the Groundnut.

THE preference accorded to Indian groundnuts in the British market under the Ottawa Agreement is considerably neutralised by the poor quality of the Indian nuts as evidenced by the high free fatty acid content of the consignments from this country, the nuts from the Coromandel Coast ports being particularly bad in contrast with those from the West Coast ports, Mormugao and Bombay. An investigation into the causes affecting the quality of the groundnut has been undertaken by J. J. Patel and C. R. Sheshadri and the results of a study of the rate of oil formation and the effect of early harvest on the oil content are published (*Indian J. of Agr. Sci.*, 1935, **5**, Part II). There is, throughout the period of development of the seed, a gradual and uniform

gain in the oil content and reduction in the free fatty acid content. The harvest of groundnut even one week before the kernels are fully ripe increases the free fatty acid content and reduces the oil content by about five per cent. Premature harvest is thus suggested as one of the causes of low quality. The other effects of such early harvesting such as the high moisture content and the need for prolonged drying and deterioration by fermentation are being studied.

Factors affecting the Absorption of Selenium from Soils by Plants.

ANNIE M. HURD-KARRER records the results of further studies on the toxicity of selenium to plants, now that the subject of this toxicity has assumed importance, owing to the fact recently established that this toxicity is communicated to animals growing on such vegetation (*J. Agri. Res.*, 1930, **50,** No. 5). The work relates to pot culture studies conducted with two different kinds of soils "the Keyport clay loam" and "Pierre clay". Of the 17 different kinds of plants grown, the cruciferæ mustard and Broccoli absorbed the largest quantities, 1240 and 1180 parts per million respectively, while at the other extreme come the grain crops, and about midway the other crops, *viz.*, sunflower, flax, sweet-clover, alfalfa pea and spinach. The cruciferæ showed no outward signs of suffering or abnormality though they absorbed the largest quantities, while the gramineæ generally suffered most, the intermediate class remaining normal with the exception of the sunflower. The factors affecting the absorption by wheat of selenium added as sodium selenate to the soil and the resulting toxicity to this crop are summarised as available sulphur, soil type, percentage of sand, method of adding selenium, the form of selenium added and the growth of previous crops. It is suggested that the tendency of a crop to absorb selenium depends on its tendency to absorb sulphur, as in the case of the cruciferæ. Sodium selenate is absorbed by wheat more in the Pierre clay than in the Keyport clay loam. Applications of free sulphur reduce the absorption by wheat of the naturally occurring selenium in soils as well as that added as sodium selenate. Gypsum is similarly effective. The addition of quartz sand to Keyport clay loam increases the toxicity of the selenate in proportion to the percentage of sand. Sodium selenate is not easily leached and is partially retained in the upper layers. Elemental selenium is apparently unavailable and non-toxic to wheat at least in quantities up to 200 parts per million in Keyport clay loams. The selenium was more toxic in the form of sodium selenate than in the form of selenite. Sodium selenate was either changed to a less toxic form or reduced to a sub-toxic concentration by the growth of successive crops of wheat.

A. K. Y.

The Duration of Life in an Albino Rat Population.

B. P. WILSON AND N. M. SHEARD (*Proc. Roy. Soc. Edin.*, **55**, Pt. 1) have, for the purpose of presenting the data on the life span of the albino rat, divided its life into two phases. The first phase comprises the span of life spent by the rat in greater or less dependence on its mother; this phase ends during the fourth week post partum. The second phase comprises life after weaning. During the period following weaning very few animals died under the conditions in which they were maintained.

Data relating to 250 litters chosen at random are presented where the total number of young in these litters was 1,607. Of these a total of 492 animals died, or were killed by their mothers before the age of 30 days; while 1,115 survived upto or beyond this age. This would correspond to a death rate during this first phase of about 30 per cent. It was found difficult to establish in any given case whether death of either a litter or a single young was due to low vitality or to accidents such as cannibalism or squashing of young by the mother because the latter fails to assume the appropriate "nursing posture". These factors were eliminated when once the young was separated from their parents. It has been shown that not only is the mean duration of life shorter in males but the terminal age reached by females exceeds the terminal age of males. The force of mortality rises after the ninth month of life in geometrical progression.

Foetal Respiration.

J. BARCROFT'S Croonian Address on Fœtal Respiration (*Proc. Roy. Soc. Lond.*, 1935, **118** (B), No. 808), attempts to state the principal facts known about the subject in the Mammalia. Needless to say that the

respiratory system goes hand in hand with that of the circulatory system. The umbilical arteries convey blood deficient in oxygen to the placenta, while the richer blood returns to the inferior vena cava by means of the umbilical veins. It is pointed out that the volume of blood passing through the fœtal heart and the oxygen consumption of the fœtus bear a relation to the weight of the fœtus itself, though in the case of the rabbit, the placenta reaches its maximum size before the culmination of the progressive growth of the fœtus. And on account of the rise in arterial pressure, more blood passes through the fully grown vascular bed in the placenta. Moreover the oxygen utilised by the fœtus bears a constant relation to the weight of the fœtus over last half of fœtal life. Towards the end of pregnancy the relationship stands thus: On the fœtal side a rapidly growing fœtus with a fœtal irrigation of the placenta and the consumption of oxygen with reference to the weight of the fœtus is present while on the maternal side neither the blood flow nor the size of the placenta increases. Therefore the "Oxygen difference" between the blood in the umbilical artery and vein should be the same whilst the maternal blood leaves the uterus increasingly reduced as pregnancy advances. That this is so is clearly shown by the dark blood emerging from the pregnant side of the uterus of the rabbit, and as regards the oxygen difference, the factors involved in this are that "the oxygen breaks away from the hæmoglobin of the mother, becomes dissolved in the plasma of the maternal blood and attains a certain partial pressure in that plasma. It then diffuses to the plasma of the fœtal blood in which it necessarily exists at a lower pressure than that which it set up in the plasma of the mother. The oxygen then passes to the hæmoglobin which it saturates up to whatever point may be possible at the partial pressure in question." Further it has also been noted that "the placental membrane is incapable of maintaining any considerable difference of pH between the maternal and fœtal plasma and that the hæmoglobin of the fœtus is different from that of the mother. Regarding the passage of blood in fœtus it has been long known that most of the arterial blood arriving by the inferior vena cava enters the left ventricle after passing through the foramen ovule into the left auricle; from the ventricle a large part enters the carotids and proceeds to the head region. The blood from superior vena cava enters the right ventricle through the right auricle; from the ventricle the blood is projected through the ductus arteriosus into the aorta and the mixed blood passes to the body. Of the 300 c.c. of blood which traverses the fœtal heart, about 150 c.c. goes to the head and other 150 c.c. to the abdominal aorta; of the latter 150 c.c. perhaps 100 c.c. goes to the placenta for aeration and 50 c.c. to the body of the fœtus for the nourishment of the same." Thus a great volume of blood finds its way through the ductus arteriosus but how this flow is stopped at the time of birth is left unanswered since it is purely a post-natal problem.

The Charnockite Series of Uganda, British East Africa.

EVER since Sir Thomas Holland recognised the Charnockite series in India as intrusive plutonic rocks, similar members have been studied in other areas, but still the origin of such rocks has not been finally determined. Some petrologists believe that charnockites are the result of assimilation of argillaceous sediments, while others like Vredengurg hold that metamorphism alone is responsible for the formation of such a group of rocks ranging from acid to ultra-basic with a uniformity of character. Adams who studied the charnockite rocks of Ceylon could not come to any definite conclusions. A comprehensive study of the charnockites from Uganda, British East Africa, has been made recently by A. W. Groves (*Q.J.G.S.*, **91**, No. 362). His study includes many chemical analyses, comparison with similar rocks in other areas, especially in India, and a detailed study of the development of Hypersthene. At the end of his paper he has tabulated a series of arguments to show that the charnockites do not result from the assimilation of sediments by magmas. The marked presence of "dry minerals," universality of secondary characters, linear arrangement of minerals and "the appearance of successive ferromagnesian minerals in the reverse of the accepted order for plutonic rocks of the calc-alkali series" have led him to conclude that the charnockites of the Uganda series of rocks are the result of plutonic metamorphism of normal igneous rocks. In view of such a conclusion by Groves, it is desirable to review the study of Indian charnockites to aid their correlation with similar rocks occurring in distant parts of the globe.

The Correlation of the Pre-Cambrian Granites by means of Heavy Mineral Analyses.

In many localities correlation of isolated outcrops of igneous rocks by thin sections and field studies are beset with numerous difficulties. In recent times such obstacles have been overcome to a certain extent by the study of the heavy mineral analyses, and in most cases successful correlations have been established. J. T. Stark and F. F. Barnes (*Geological Mag.*, 1935, No. 854) during the course of their study of the closely related Pikes Peak and Silver Plume Granites of the Pre-Cambrian Age in the Sawatch Range of Central Colorado have shown by means of the heavy mineral analyses that outcrops belonging to the two series of granites differ fundamentally, in their heavy mineral constituents. In the Silver Plume granite there is a large percentage of Zircon, while the Pikes Peak granite is characterised by a large percentage of Titanite. By a series of curves they have shown that though there are a large number of minerals common to both the series of granites yet the relative proportions of certain of the important minerals like Zircon and Titanite are sufficiently marked for being made use of in correlation.

Sugar Industry of India, 1933—34.*

The year 1933–34 was one of general depression in the sugar industry of the world. The total production of sugar during that year exceeded the consumption by about 740,000 tons. But mainly as a result of protective tariffs, the Indian sugar market did not suffer any dislocation and on the other hand accommodated the produce of 112 factories which operated during that year. There was a marked decline in the total sugar imports into India. On the cultivation side, though the acreage under cane was less than in 1932, the cane grown exceeded the figure for that year in consequence of the increasing adoption of improved varieties of cane. The severe earthquake in Bihar on 15th January 1934 was responsible for a large damage to the cane crop. The factories designed to work were 123 during 1933–34 but only 112 were in operation. The total produce was 453,965 tons which was 163,788 tons more than the produce of 1932–33. In spite of a large number of new factories working and the loss in Bihar due to earthquake, the average recovery for the whole of India showed a slight increase over the previous year's figure.

Advancement in technical and scientific work was not lacking. The research stations in Coimbatore and Pusa and those in other provinces demonstrated the increasing usefulness of many Coimbatore varieties of cane which are rapidly ousting the local varieties out of cultivation. Financed by the Imperial Council of Agricultural Research the work on the design of a small power-driven mill started in 1931 resulted in success and the mill was standardised for cane conditions in Bihar and Orissa.

Of great importance to Indian Sugar Industry are the Government of India Acts Nos. XIV and XV of 1934 which provide for the levy of an excise duty of factory sugar and empower local governments to restrict sugarcane dealings and fix cane prices in such a manner as to secure to the growers a fair price for their produce.

The total value of sugar machinery imported into India during 1933–34 was Rs. 3.36 crores of which nearly Rs. 2 crores were spent on British machinery alone. The import of machinery in 1932 was only half of this value.

Besides the 453,965 tons of sugar made in factories direct from cane, 225,000 tons were produced by indigenous process and 60,000 tons by refineries making a total production of 738,965 tons. Consequent to this large production there was also a sharp fall in the quantity of imported sugar. Gur production in 1933–34 was 10.8 per cent. higher than in the previous year with a corresponding fall in molasses imports.

The position of sugar trade of Java and Cuba is of interest. Java suffered enormous fall in her sugar exports owing to severe competition from other countries and the large increase in the production of British India. Under the management of sales by the 'NIVAS', quantities of sugar in excess of the production of 1933–34 were disposed of. During the year under review only 99 factories operated in Java as against 166 in the preceding year. The acreage under cane was only 208,947 in 1933–34 as against 423,924 in 1932. The Cuban sugar trade of 1933 was influenced considerably by the inflationary policy of the U.S. Government, the attempt at the formation of a sugar crop restriction and marketing agreement, the possibility of reduction in Cuban duty and finally the overthrow of Mochado Government in Cuba.

Though the world sugar industry of 1933–34 shows a large excess of production over consumption figures in contrast to the previous year, the outlook of Indian sugar industry is definitely better to-day, inasmuch as fear of over-production is lessening. The excise duty has put a wholesome check on excessive expansion of factories and, at the same time, the country has shown signs of increasing sugar consumption.

G. Gundu Rao.

* Review by R. C. Srivastava, Supplement to the *Indian Trade Journal*, Aug 15, 1935.

Science Notes.

Improvising a Paraffin Bath.—Mr. Beni Charan Mahendra, St. John's College, Agra, writes under date 24th August, 1935 :—"Last year, as I did not have sufficient money to buy a paraffin bath for my room, I made one for myself according to a suggestion of McClung.[1] The apparatus did not cost me more than five rupees, and besides being simple, it works as efficiently as an elaborate water-bath with a thermo-regulator can. I pass on the suggestion in the hope that somebody in a situation similar to mine may find it useful.

All that is required is a 100–150 watt gas-filled, electric bulb, a small glass beaker and a clamp-stand. The apparatus is set up as shown in the figure, the beaker is filled up with the paraffin

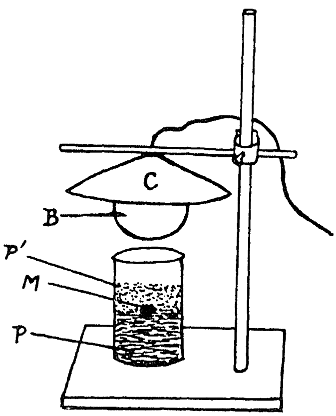

Fig. 1.

The Improvised Bath.

B, electric bulb ; C, Shade for the bulb ; P, Solid paraffin; P′, Molten paraffin ; M, Object to be infiltrated.

of desired melting-point, and the bulb is lighted. The heat given out by the bulb melts the upper layers of paraffin, while the lower layers remain solid. According to the principle of latent heat, the temperature of the paraffin cannot rise above its melting-point as long as there is some solid paraffin left over. The height of the bulb can be adjusted with this end in view, and there is absolutely no necessity of any thermo-regulating device. The object to be imbedded can be transferred to this bath as soon as the upper paraffin has melted. To keep off dust from getting into the paraffin, a sufficiently large wooden-case can be modified to accommodate the whole apparatus inside.

Another cheap method of building a paraffin bath for oneself, which I have not tried, is given by Ballantyne.[2]

Recent Archæological Discoveries in S. India.—The discovery of (1) *an inscribed pot from Guntur District,* by Prof. K. A. Nilakanta Sastri, (2) *a Chola Image of Manikkavachaka and some other Images found associated with it,* by Mr. T. N. Ramachandran, and (3) *Prehistoric pottery from the Cuddapah District, including a sarcophagus in the form of a ram,* by Mr. M. D. Raghavan, are among the important announcements made at a recent meeting of the Archæological Society of South India. The pot described by Prof. Nilakanta Sastri bore an inscription in Brahmi characters of the end of the second or the beginning of the third century A.D. and probably recorded that the contained ashes were those of Aryadeva, a man known to have been a pupil of Nagarjuna. The image of *Manikkavachaka,* discovered by Mr. T. N. Ramachandran, was found buried near Madukkur in the Pattukottai Taluk of Tanjore, and bore an inscription in the hand in characters of the period of later Cholas. Mr. M. D. Raghavan's discovery refers to pottery found at Markapuram in the Badval Taluk of Cuddapah District, at a depth of six feet with a unique *sarcophagus.* The sarcophagus possessed a clearly modelled head of a ram the curved horns being emphasised but the ears and tail omitted. It contained a fractional human interment, evidently a secondary burial. The bones were much decayed. The worn state of the molars and the condition of the skull sutures show them to have come from an adult person. It is hoped that this find is only the beginning of a series of similar ones, ultimately leading to the establishment of a much-needed pottery time-scale for South India.

Some Chemists of Yesterday—formed the subject of the inaugural address to the Chemical Society, University of Mysore, delivered by Dr. Gilbert J. Fowler, D.Sc., F.I.C., on Saturday, the 31st August at Central College, Bangalore. The address was largely autobiographical and contained glimpses of the inspiring work and character of the giants of chemistry, Professors Roscoe, Schorlemmer, Victor Meyer, Gatterman, Dixon, Perkin and others. "The chemist who had learnt his science during the last decade or so, would seem to belong to quite a different school from that of the preceding fifty years." "Modern Chemistry is concerned with the intimate nature of atoms and molecules and their individual reactions, while in the days before isotopes we dealt with mass reactions and were concerned mainly with mass phenomena."

Referring to the teaching of chemistry in India, the lecturer often felt that Indian students suffer under a disability in that much of their training is of necessity at second hand. "Nothing at second hand, *e.g.,* could equal the impressiveness of a lecture by Roscoe on Vanadium, when he described the researches which had enabled him to place this element in its proper place in the periodic table and showed samples of the numerous compounds isolated in the course of the research. In this way it was learnt how new knowledge was actually made and the whole subject was removed from the text-book atmosphere." The number of those who have made real "Path-breaking" research is

increasing in India so that the Indian student has not necessarily to go to Europe for Education. Dr. Fowler concluded the address with a quotation from a recent discourse of Professor Bone, himself a student and colleague of Dixon, as embodying an ideal which may be kept in mind by the students of present day.

"It was a rigorous school of research to which we were admitted, and its discipline was such as only strong minds could stand. As I have already said elsewhere, Dixon's singularly clear and penetrative mind referred everything to the final test of a well-ordered experiment critically carried out without hurry or bias and with the results checked at every point. He impressed upon all the paramount importance of accuracy and truth, together with the highest standard of experimental proof step by step, by a process of exclusion, until it had been narrowed down to a single issue, which finally had to be tested in every possible way. We were taught also to criticise our results, to eschew all rash speculation, and to limit ourselves to such explanations as were proven or provable. Our theories were to be regarded merely as working hypotheses, no more than serviceable tools for accomplishing further advances, and as such always to be subordinated to facts and discarded when outworn."

Travancore Rubber Factory.—With a view to utilising the raw materials produced in the State, a rubber factory, equipped with modern tubing machines, hydraulic presses, braiding and hose making machines, vulcanisers, spreading machines, etc., has been started at Trivandrum. Messrs. Hermann Berstorff supplied the major portion of the plant and the detailed plan and estimate were prepared by Mr. John Helen, the State Rubber Expert and Engineer, who was formerly Rubber Expert to the Lakshmi Rubber Works, Karachi. The Rubber Factory is the first of its kind in India and is a pioneer enterprise started by the State. Travancore is the largest rubber producing tract in India including the Native States, with an area of 95,800 acres, under rubber, and accounts for more than 75 per cent. of the rubber of very good quality in South India. It has large deposits of very fine China clay, an essential ingredient for the manufacture of rubber goods and plenty of educated and skilled labour is also available.

The 31st Half-Yearly Meeting of the Indian Central Cotton Committee.—The 31st Meeting of the Indian Central Cotton Committee commenced its session on the 19th of August in Bombay under the Presidentship of Diwan Bahadur Sir T. Vijayaraghavacharya, K.B.E., Vice-Chairman of the Imperial Council of Agricultural Research. In response to an invitation, His Excellency the Governor of Bombay was present. Among others present were the Hon'ble Khan Bahadur D. B. Cooper and the Hon'ble Diwan Bahadur S. T. Kambli.

In pursuance of the policy of encouraging long staple cotton in all tracts in India, suitable for it, the proposals of the Chief Agricultural Officer in Sind for the establishment of a compact block of long staple cotton of 300,000 acres in the Barrage areas of Sind by licensing of gins and presses, use of special marks in the licensed factories, seed supply organisation and organised marketing, had received the approval of the Committee at its August 1934 meeting. The Committee after a long discussion adopted a resolution urging the Local Government to translate their recommendations into action without delay and suggesting that the compact area be reserved for the growth (from specially selected government seed) of long staple cotton only, such as 289-F and N.T. and also that the Cotton Transport Act be introduced to prevent the importation of *kapas* from outside areas.

The first annual report of the Lancashire Indian Cotton Committee was considered by this Committee and it expressed its high appreciation of the efforts made by the Lancashire Committee to extend the use of cotton of Indian growth in Lancashire as described therein. The Indian Central Cotton Committee assures the Lancashire Committee of its desire to co-operate to the fullest extent possible in all matters affecting the interests of both bodies.

The Committee noted with satisfaction the Bombay Government's response to its representations for the elimination, by legislative action, of Goghari cotton in the Surat area, the spread of which in recent years has been a serious danger to 1027 A.L.F. The Local Government propose to introduce at an early session of the Council, a Cotton Control Bill on the lines of Madras Cotton Control Act, to prohibit the cultivation of Goghari cotton, its mixture with any other kind, its possession or its use for trading purposes.

The report of the Technological Research Sub-Committee was approved. It showed that a total number of 431 samples were received for tests during the period under review as against 311 during the corresponding period last year. The Committee recorded its appreciation of the valuable work of the Director of the Technological Laboratory, Matunga, whose informative brochure dealing with the work of the Laboratory for the last 11 years was considered and approved. This brochure will shortly be available to the general public.

The progress reports of 30 agricultural research schemes and 15 seed distribution schemes, all of them financed by the Indian Central Cotton Committee, were considered by the Committee and approved. The Jayawant and Gadag No. 1 Distribution and Extension Scheme was sanctioned for 5 years at an estimated expenditure of Rs. 2,66,772. A scheme for the introduction and extension of B.D. 8 cotton which is wilt resistant, in Broach District, was sanctioned for a period of 3 years at a total cost of Rs. 10,160. The Committee approved of the idea of calling a conference of scientific workers on cotton to be held in Bombay soon after the 1936 monsoon meeting of the Committee.

The Central Provinces Government doubted advisability of prohibiting the cultivation of Garrow Hill cotton which had detrimentally affected better types in the Central Provinces and Berar. They thought that the spread of such inferior cotton could be discouraged by penalising its mixing with cotton of superior varieties and decided to undertake legislative measures to penalise the sale of mixed cotton as pure. The Committee decided to request the Central Provinces Government to reconsider the question of prohibiting the growing of Garrow Hill cotton,

as in its opinion the action which the Local Government proposes to take will not prevent the spread of this inferior cotton. The known presence of even small areas of an inferior cotton tends to lower prices in the markets where this cotton is sold and the growers of better quality cotton also suffer.

The Association of Economic Biologists, Coimbatore.—The Association of Economic Biologists which was founded five years ago, fulfils the supremely important function of bringing together the various specialists of the Coimbatore Agricultural Research Station for (1) taking stock of progress achieved in the different branches of Agricultural Science, and (2) discussions of research problems engaging the attention of the scientific officers of the station. Short notices of the activities of the Association have appeared in the columns of *Current Science* from time to time. The Proceedings of the Association issued annually reflects the activities of the Association. A brochure has recently been issued by the Association covering the period 1934–35. It comprises of six original papers and a number of highly informative lectures constituting an impressive record of the work of the Association.

Correlation between Laboratory Tests and Observed Temperatures in Large Dams.—His Majesty's Stationery Office (*Building Research Technical Paper No.* 18. Price 9*d*. net. Post Free 10*d*.)—A knowledge of the temperatures likely to be attained in large masses of concrete is of the greatest importance. The present paper shows, by comparing records made in three large dams now under construction with time-temperature curves obtained in the laboratory, that these temperatures may be predicted from data given by the adiabatic method of curing concrete. The method was described in Technical Paper No. 15. (Price 1*s*. 3*d*. Post Free 1*s*. 5*d*.)

* * *

The Effect of Lighting on Efficiency Rough Work (Tile-Pressing).—His Majesty's Stationery Office (Price 4*d*. Post Free 5*d*).—The report describes experiments undertaken to find out the effect of increasing the illumination in the case of a perfectly simple operation (tile-pressing) for which good lighting was not previously considered necessary. The results show clearly the advantage to be gained by maintaining a reasonably good level of illumination.

Van Nostrand's Chemical Annual.—Our attention has been drawn to the omission of the name of the Publishers in the bibliographical details relevant to the review of this highly useful handbook, containing useful data for analytical manufacturing and investigating chemists, chemical engineers and students, published in the July number of *Current Science* (Vol. IV, No. 1, p. 68). Messrs. Chapman & Hall, Ltd., 11, Henrietta Street, Covent Garden, London, W.C. 2, are the publishers of this important publication and they also act as agents for the book in the British Empire. The omission is regretted.

Academies and Societies.

National Institute of Sciences of India:

August 23rd, 1935.—SYMPOSIUM: *Discussion on Problems of the Ionosphere.* S. K. MITRA: The Ionosphere constitutes the vast stretches of ionised regions in the upper atmosphere, the lower boundary being at a height of about 90 kms. The upper boundary extends beyond 400-500 kms. It is explored experimentally by the study of the reflection of wireless waves. Such studies have given information about the height, ionisation density, density gradient, structure, intensity of the magnetic field, collisional frequency between electrons and neutral atoms or molecules at ionospheric height, polarisation of the down-coming waves and temperature of the ionosphere. The main ionising agency is the ultra-violet rays of the sun. S. K. BANERJI: *Thunderstorms and Magnetic Storms in Relation to Ionosphere.*—The influence of the earth's magnetic field is such as to make the ionosphere an aelotropic medium and owing to the difference in the group velocities of the two components, a single wireless pulse may be split into a doublet. Magnetic storms are connected with abnormal ionisation and this is probably associated with high speed charged particles from the sun. There appears to be extraordinary variability in ionospheric weather and it would be interesting to correlate them with magnetic variability. The sudden appearance of bursts of abnormal ionisation is associated with thunderstorms. There is a close relationship between thunderstorm activity and sun spots. G. R. TOSHNIWAL: *Ionosphere at Allahabad.*—By the method of Breit and Tuve, it has been found that normally a 4-kilocycle wave is reflected from the F-layer at a height of about 250 km. The ionisation decreases gradually after sunset and the equivalent height from which the reflected wave emanates gradually increases and about 2 hours after sunset the 4-kilocycle wave is not reflected from the ionosphere. At the time of the lunar eclipse on January 19th, 1935, using a 75-metre wavelength it was found that the equivalent height of the F-layer was almost constant up to 18 hours 20 minutes, after which it rapidly rose to 400 km. and then began to fall and was minimum when about three-quarters of the moon was dark. After totality the equivalent height again began to increase and within 20 minutes no echo could be seen due to electron limitation. P. SYAM: *The D-Layer.*—The detection of echoes from a virtual height of about 55 km. gives direct proof to the existence of a low layer at this height during the day time. The echoes are of infrequent occurrence. Other evidences also exist in support of the presence of the D-layer. It has been found that during the day time there is a frequency band which is reflected from the E-region. The upper limit of the band is due to the penetration of the E-layer, and may be termed the "penetration limit". The lower limit which may be termed the "Absolute limit" is due to the absorption by the D-layer on account of large collisional frequency present therein.

Indian Academy of Sciences:

August 1935. SECTION A.—P. S. SREENIVASAN: *Raman Spectra of Isoprene, Dipentene, and Ocimene.*—Specially chemically pure substances have been prepared and studied. T. S. SUBBARAYA: *Analysis of the Spectrum of Trebly Ionised Zinc: Zn IV.* C. S. VENKATESWARAN: *The Raman Spectra of Iodic Acid and the Alkaline Iodates as Solids and Solutions.*—The dissociation of iodic acid is incomplete even at concentrations of 0·5 N. It is suggested that the acid is polymerised in the solutions to an appreciable extent, the polymerisation decreasing with dilution. The IO_3 ion exhibits all the four vibration frequencies and two parallel vibrations exhibit splitting, indicating that the IO_3 radical is pyramidal in structure with the I atom close to the plane of the O atoms. A number of low frequency oscillations have been observed and an explanation suggested. R. ANANTHAKRISHNAN: *On the Convergence Error in Depolarisation Measurements.*—It is shown that the observed values of the depolarisation would be higher than the genuine values by a correction factor which involves the square of the angle of convergence. The necessity for the perfection of the optical parts used in depolarisation work is emphasised. N. S. NAGENDRA NATH: *The Dynamical Theory of the Diamond Lattice.—Part III. The Diamond-Graphite Transformation.* The temperature at which diamond becomes unstable and transforms to graphite is calculated and is shown to be in good agreement with the experimental determinations. R. ANANTHAKRISHNAN: *Redetermination of the Depolarisation of Light Scattering in Gases and Vapours.*—The corrected results with improved technique yield in general much smaller values than hitherto reported: the results are in greater agreement with theory. P. S. VARADACHARI: *Influence of the Formation of Hydrates on the Diamagnetism of Chemical Compounds.*—Results are reported on the aqueous solutions of sulphuric acid, acetic acid and sodium sulphate, over the complete range of concentrations. S. CHOWLA: *Irrational Indefinite Quadratic Forms.* M. SURYANARAYANA: *Positive Determinants of Binary Quadratic Forms whose Class-number is 2.* I. CHOWLA: *On Sums of Powers.* G. S. DIWAN AND V. V. NARLIKAR: *A Practical Financial Transaction.*—It is proved straight from the definition that a *practical* transaction admits of only one rate of interest. The multiplicity of the rate of interest for a transaction shown by Misra is only mathematically possible. G. R. GOGTE: *Chemistry of β-Aryl Glutaconic Acids. Part II. Condensations with Phenolic Ethers.* H. GUPTA: *On the P-Potency of G* $(p^{\alpha}-1, r)$. B. VENKATESACHAR AND L. SIBAIYA: *Iridium Isotopes and their Nuclear Spins.*—The hyperfine structure patterns of some of the significant arc lines of iridium have been studied. Two isotopes of mass 191 and 193, abundance ratio 1:2, and nuclear spins $\frac{1}{2}\frac{h}{2\pi}$ and $^{3}/_{2}\,\frac{h}{2\pi}$ have been distinguished. The estimated atomic weight 192·4 shows that the accepted chemical atomic weight 193·1 is too high.

SECTION B.—H. CHAUDHURI AND P. L. KOCHHAR: *Indian Water-Moulds—I.*—The cultural characteristics of 20 species of water-moulds, some of which have not been noted before in India, have been described and fully illustrated. S. S. PATWARDHAN: *On the Structure and Mechanism of the Gastric Mill in Decapoda VI.*

The Structure of the Gastric Mill in Natantous Macrura—Penœidea *and* Stenopidea: Conclusion. —The various types of gastric mills found in the Decapoda can be arranged in a series ranging from simple to complex. Reptantous habit is associated with the possession of a complex gastric mill and simple mandibles and the Natantous habit with the possession of a reduced gastric mill and complex mandibles. H. S. RAO: *The Structure and Life-History of* Azolla pinnata *R. Brown with Remarks on the Fossil History of the Hydropteridex.*—Fertilisation takes place in September or October. The resulting fresh plants mature in spring. By about April the sporocarps ripen and are shed. The spores rest during summer. The megasporocarp with the attached massulæ floats up before fertilisation. A. SREENIVASAN: *Investigations on the Rôle of Silicon in Plant Nutrition. Part II. Adsorption of Silica in Soluble Forms by Colloidal Oxides of Iron and Aluminium.* The possible significance of silicate adsorption in relation to phosphorus resorption in soils is indicated. Y. V. NARAYANAYYA AND V. SUBRAHMANYAN: *Estimation of Nitrogen by Fumeless Digestion. Part I.*—The material is first boiled with manganous sulphate and sulphuric acid (2 : 1) for 30 minutes. Potassium dichromate is next added and the boiling continued for a further period of 30 minutes after which the digest is reduced with zinc and distilled with excess of alkali, as in the Kjeldahl procedure.

The Academy of Sciences, U.P.:

An ordinary monthly meeting of the Academy was held at Allahabad on the 27th July, with Prof. N. R. Dhar, President of the Academy, in the Chair. The following papers were read and discussed:—

(1) "The Chemical Examination of the Fruits of *Lagenaria vulgaris* Seringe (bitter variety)". Part I. The Constituents of the Oil from the Seeds," by Radha Raman Agarwal and Shikhibhushan Dutt, Chemistry Department, Allahabad University, Allahabad. (2) "Colour and Constitution of Dyestuffs derived from Flourenone," by Mohit Kumar Mukerjee and Shikhibhushan Dutt, Chemistry Department, Allahabad University, Allahabad. (3) "New Trematodes of the Family *Lecithodendriidæ* Odhner, 1911, with a discussion on the classification of the family," by H.R. Mehra, Zoology Department, Allahabad University, Allahabad. (4) "Preliminary Account of New Trematodes with Ani." by S. C. Verma, Zoology Department, Allahabad University Allahabad. (5) "A Note on the Colouring Matter of the Flowers of *Lantana camera* Linn.", by Jagraj Behari Lal, Chemistry Department, Allahabad University, Allahabad.

At the meeting of the Academy held on the 16th August 1935, the President announced that the Allahabad University had renewed the grant of Rs. 500. The following papers were read and discussed:—

(1) "Further Experiments on the Fixation of Atmospheric Nitrogen in the Soil and the Utilisation of Molasses as a Fertilizer," by Prof. N. R. Dhar and Mr. S. K. Mukerjee.—The experiments of Prof. Dhar lead to the conclusion that the oxidation of the energy-rich carbohydrates present in the molasses causes the fixation of atmospheric nitrogen leading to an increase of ammonium salts and nitrates in the soil. (2) "The Nitrogen Atom and the Molecule," by L. S. Mathur. (3) "Contributions to the Digenetic Trematodes of the *Microcheroptera* of Northern India, Part III. —New Distomes the genus *Mesodendrium faust* (1919)," by B. P. Pande. (4) "On Evidences for a Lag Effect in Zeuner's Data on Saturated Water Vapour in Landolt and Bornetein's Table," by Prof. Satyendra Ray. (5) "On Evidences of Tidal Waves in an Insulated Molten Interior as obtained in some Recent Severe Earthquakes," by Prof. Satyendra Ray.

A Symposium on the 'Theory of Relativity' was held on the 17th August. Sir Shah Muhammad Sulaiman opened the discussion. In the course of his speech, he answered the criticisms of Mr. D. R. Hamilton and Mr. Satyendra Ray. He predicted that the deflection of light from a star passing the sun would be between 2″.32 and 2″.45 as against Einstein's value of 1″.75. The spectral shift of light from the limb of the sun according to his theory will be 0.00676, a value which was nearly the same as that obtained by Evershed in 1918. Einstein's theory gives the value as 0.0084. Professors A. C. Banerji, Satyendra Ray and M. N. Saha were the other speakers. Dr. Gorakh Prasad and Mr. Rama Nivas Rai also took part in the discussion.

Reviews.

INTRODUCTION TO PHYSICAL SCIENCE. By Carl W. Miller, Ph.D., Associate Professor of Physics in Brown University, New York. (John Wiley & Sons, Inc.). Price 5*s*.

In this second edition of the book the latest developments in Physics such as Artificial Radioactivity find a place and are treated in a manner conforming to the object which the author has in view in writing it, *viz.*, to provide a one-year general course to the student who may not specialise in the subject afterwards. The method of treatment is clear and attractive avoiding all mathematics unnecessary to an elementary treatment. In these days the revolutionary advances in Physics have not only greatly influenced civilised life but have given a distinct new orientation to philosophic thinking with the result that no one claiming to be a cultured member of society can afford to be ignorant of the fundamental teachings of modern Physics. Here is a book which we can confidently recommend to one who is anxious to get a correct idea of what modern Physics means. Relativity, Quantum Theory, Wave Mechanics, Electron Diffraction and Nuclear Physics are all dealt with in a manner acceptable to the elementary student of the subject. The examples at the end of each chapter are appropriately chosen to illustrate the main points treated in the corresponding chapters. To the first year students in Indian Universities the book under review will be invaluable.

B. V.

PHYSICS FOR COLLEGE STUDENTS. By A. A. Knowlton, Ph.D. (McGraw Hill Book Company Inc., 1935.) 2nd Edition, pp. 623. Price 21*s*.

This book is written by a professor of physics in an American College, and is meant for students in American Colleges who take up an elective course of study in Physics for their graduate course. These students do not propose to continue their study of Physics beyond their one year's prescribed course, and to meet their requirements the author has written the above text-book. From it a knowledge of the essential parts of Physics can be obtained by a student in the course of one session's study of four hours a week. It is written more from a humanistic rather than a purely technical standpoint. It is shown how during the ages man has gradually acquired a mastery over his physical environment and thus been able to harness the forces of nature for his own use. During the course of this evolution he has gradually developed a mode of interpreting the natural phenomena which is incorporated in what is known as scientific explanation. In accordance with this standpoint of the author, the methods of measuring work and the different kinds of energy, mechanical, heat and electrical, are introduced early in the book. The whole of Physics is surveyed in about fifty short chapters, and the author has incorporated a large amount of modern Physics in it. The treatment is on the whole descriptive with a little of essential mathematics thrown

in. The book does not follow the usual sub-divisions of the subject into Mechanics, Sound, Light, etc., and in arranging the subject-matter the author had partly the pedagogical method of 'soaking in process' in view, *viz.*, so much and only so much of a subject is introduced as is required at that point. As its next introduction, something further is added to the material which has become part of the mental background of the student through use.

As will be seen the book is written from a novel standpoint and contains many valuable features. So far as the reviewer can judge, the book will not fit in with any of the syllabuses on Physics prescribed by the different University examinations of this country, but it can be recommended to all students preparing for the pass B.Sc. examinations, for supplementary reading.

LEHRBUCH DER THEORETISCHEN PHYSIK. By G. Joos. (Akademische Verlags Gesselschaft, Leipzig.) 2nd Edition. Price RM. 24.

The attempt to present the whole of mathematical physics in a single volume is a bold venture and necessitates a careful selection of the subject-matter and sometimes a short-cut through the mathematical foundation. The particular value of this book in the opinion of the present writer lies in the fact that it shows the edifice of Physics unburdened by experimental details; yet nowhere does the mathematical deduction make the reader forget the physical conceptions. German scientific literature has always excelled in text-books on mathematical physics and it is extremely satisfactory that this series of valuable textbooks has been supplemented by this concise volume. The new English edition can be strongly recommended to the post-graduate students and teachers of this country. After a first introductory chapter, in which the mathematical tools of the Physicist are treated, the author deals with mechanics and hydrodynamics, and relativity theory in the second book. The different chapters of the third book deal with the classical theories of electrodynamics and optics, and the fourth with the electronic theory of both. Again thermodynamics which follows, is treated first in the classical way and then as kinetic theory. The seventh and last book deals with the structure of atoms and molecules and the theory of spectra, and here again a clear division between quantum theory and quantum mechanics is introduced. Wavemechanics, the wavemechanical theory of valency and dispersion and the structure of the nucleus are about the last questions which are treated.

* * *

SOLID GEOMETRY. By L. Lines, M.A., B.SC. (Messrs. Macmillan & Co., Ltd., London, 1935). Pp. 292. Price 6*s*. net.

The purpose of the book appears to be partly to provide a treatise on Solid Geometry (Euclid XI), as is usually taught in our Intermediate courses, but with an elaborate collection of examples; and partly to provide a preface to the study of crystallography, and arrangement of atoms in crystals. The first six chapters deal with the theorems on Solid Geometry as are usually taught in our intermediate classes. These are followed by two chapters on Mensuration and one on Centroids. Then follow chapters on Rabatment, Polyhedra, Semi-Regular and Star-Polyhedra, Space-Lattices, Sphere-Packs, Patterns and Crystals.

The book deserves attention from every teacher of the subject on account of its wide range of problems, and variety of subjects. But we cannot help remarking that there is too much of drilling of pure geometrical methods for proving results many of which could be easier proved and better appreciated by the methods of analytical geometry and the calculus. No doubt, the use of purely geometrical methods to a certain extent is highly desirable and wholesome in these days when there may be a tendency to use the analytical machines too often; but if the methods of pure geometry are carried too far, they can only savour of pedantry on the author's part, and constitute what is often called "murdering of mathematics".

STRUCTURE NUCLÉAIRE: par G. Guében. (No. 247 of the Actualités Scientifiques et Industrielles). (Hermann et Cie, Paris, 1935.) Pp. 36. Price 10 *fr*.

The structure of the nucleus is a problem which is being actively attacked by a number of methods but we cannot say that there is any definitely established solution yet. The view that the nucleus consists of protons and electrons, the latter having combined as far as possible into α-particles, has been given up and we now think of the

nucleus as consisting of protons and neutrons. Although there are strong grounds for believing that pairs of protons and neutrons are combined as far as possible into α-particles, there are many authorities who consider the protons and neutrons to exist without such combination. Admitting, however, that there are the maximum possible α-particles formed, one proton will be left over when the atomic number is odd. Walke has tried to maintain the view that this extra proton is always combined with a neutron forming a deuton. However, the statement that any particular nuclear property is present when there is a deuton is simply equivalent to admitting the existence of the property when there is an odd proton, *i.e.*, when the atomic number is odd. The brochure under review develops Walke's proposition in detail and tries to answer some objections to that view. There is one nuclear property, however, which, in spite of its importance, has not been considered in the present book—we mean the magnetic moment of the nucleus. Experiment having shown that the deuton has a magnetic moment of 0·75 nuclear magneton, the large magnetic moments of Li, Al, etc., for example, cannot be explained if the odd proton is supposed to be combined with a neutron to form a deuton. The time is not ripe for taking any particular theory of the nucleus as finally established, but the book will serve to render one aspect familiar to French readers; the danger, however, remains that the reader may mistake the thesis of the book for the accepted view.

RAYONS COSMIQUES. par B. Rossi. (No. 248 of the Actualités Scientifiques et Industrielles.) (Hermann et Cie, Paris, 1935.) Pp. 48. Price 12 *fr.*

Our conception of the nature of cosmic rays has undergone a transformation in recent years mainly as the result of the work of J. Clay, B. Rossi and A. H. Compton. While the earlier view was that cosmic rays were very short γ-rays, the current opinion is that they almost entirely consist of particles. Compton distinguishes three groups A, B and C according to their penetrating power and shows reasons to believe that they consist of α-particles, electrons both positive and negative and protons respectively. The change of view was the result of the discovery of the latitude effect and its variation with height. The experimental facts and their significance are presented in a masterly way, the account being clear and authoritative. The language is also readable, the results being expressed definitely but with cautious reserve. Some other up-to-date accounts of cosmic ray research have recently appeared, particularly A. H. Compton's Guthrie Lecture (*Proc. Phys. Soc. London*, 1935, **47**, 747–773). Rossi's monograph can be advantageously studied side by side with Compton's paper, the two supplementing each other to the reader's great advantage. We heartily recommend this monograph to all students of modern problems in Physics and congratulate the publishers on securing such an authoritative presentation of a subject of great interest and importance.

DYNAMICS OF POPULATION: SOCIAL AND BIOLOGICAL SIGNIFICANCE OF CHANGING BIRTH-RATES IN THE UNITED STATES. By Frank Lorimer and Frederick Osborn. (The Macmillan Company, New York, 1934.) Pp. xiii+461. Price 15*s*.

Students of Social Demography will welcome this valuable addition to the scanty literature on the subject. The authors who have both practical and theoretical knowledge of the problems they are handling come to certain useful and important conclusions of the population trends in the United States. These, we hope, will be of interest not only to the American students but to all who are working on the subject throughout the world. The purpose of the book, as the sub-title implies, is a scientific study of the causes and effects of population changes.

The population of the United States is divided into classes under various headings such as national origin, occupation, social and economic status, etc. As a sequel to these a brief survey of the physical and mental characteristics of these groups is given laying stress on the variations in intellectual and cultural development. A clear line of demarcation is drawn between the rural and urban population pointing out clearly the differences in physical and mental attainments of both. With the data derived from these studies the authors have endeavoured to forecast the relative strength of the various national groups in the population of the next century.

Another important topic perused at length is the difference in reproduction rates among the groups, as the classes having higher birth-rates and greater vitality will predominate in the long run. It is also a painful reality that in areas least able to support a teeming population do we obtain maximum fertility among the groups. As a result of this investigation, the authors deduce that a sorting process is at work, establishing gradients in intellectual capacity and so intelligence ratings are bound to differ for such classes. It is abundantly clear that capacities are inherited and so a slight enhancement in the reproduction rate of these groups that have a higher average capacity for intelligence and a correspondingly slight decrease in the rate of reproduction of the less gifted groups would largely increase the number of individuals of higher capacity and considerably decrease the number of imbeciles. But it is painfully brought home to us that the present population trends are heading to the opposite result.

The other problems discussed are the causes for the observed population trends and the conclusion arrived at is that reproduction rates among the groups occupying high social levels are low. Nevertheless it is clear that economic factors and the particular method of family limitation prevalent among these groups largely determine fertility.

Another conclusion put forward is that no group with high standards of living and a knowledge of the methods of birth control can be looked forward to be self-replacing permanently unless conditions conducive to fertility intervene.

The last and perhaps the most important subject dealt with in the present volume is the possibility of social control and the suggestion that city planning and increasing the economic security of young couples holds out the greatest promise for such control.

It is needless to expatiate on the usefulness of the book to those for whom it is intended and we hope that similar careful and scientific study of the vital problems of population will be undertaken by international co-operation and collaboration.

TRAVANCORE GOVERNMENT ARCHÆOLOGICAL DEPARTMENT ADMINISTRATION REPORTS FOR THE YEARS 1108 M.E. AND 1109 M.E. (1932–33 AND 1933–34).

The Annual Reports of the Travancore Archæological Department are, unlike the detailed reports of the Government of India, merely brief Administration Reports. They have both the advantages and the disadvantages of brevity and cheapness and perhaps approach more nearly to punctuality than the bulkier and more detailed reports of the Government of India.

Under the head Conservation one would perhaps be justified in expecting a more detailed statement of the arrangements made and the expenditure incurred for the conservation of the ancient monuments in the State. It is difficult to believe that only Rs. 500 were spent in 1108 M.E. for this purpose and that nothing was spent in 1109 M.E. The Archæological Department

may collect the relevant information from the Department of Public Works, and publish it. Whenever any repairs are to be done to any of the ancient monuments of the State the approval and co-operation of the Archæological Department ought to be obtained, and the latter should keep a record of all such work.

The scientific work done by the Department during the years under review appears to be considerable both in quality and quantity. In the year 1108 M.E., 43 new inscriptions were examined, the earliest stone inscription being dated Kollam 301 (1126 A.D.). Brief notices of most of the inscriptions and a tabulated statement about them are given in an appendix. The report for 1109 M.E., however, is silent about inscriptions. It may be suggested that a systematic collection of epigraphical records may be made and the texts of those collected may be published from time to time. The coins studied during the year also need more detailed descriptions and clearer illustrations.

Two valuable items published in the report for 1108 M.E. are an Archæological map of the Travancore State and a table tracing in detail, of the evolution of the Vatteluttu alphabet, both of which would be found highly useful to scholars.

In the report for the year 1109 M.E. the chief piece of work described under 'Conservation' is the copying of the wall paintings found on the Gopura of the Temple at Ettumanur in North Travancore, which is ascribed to a period not later than the 16th Century A.D. The theme is that of Shiva's great dance on the destruction of the Demon Apasmara. A half-tone illustration of the central panel is given, and the painting is described as one of the great triumphs of pictorial art in Travancore.

Another piece of work connected with painting was the identification of the scenes and stories of the mural paintings in the Sri Padmanabhaswami Temple at Trivandrum. " In the vitality of the figures, and in the infinite variety of poses, gestures and emotions throbbing with life, lies the secret of their charm and attractiveness. Supreme examples of a wonderful combination of both ' Rupa ' (beauty of objective realisation) and ' Rasa ' (grace of emotional expression), many of these paintings have a grandeur and sublimity of conception rarely to be found in many other temples of the State."

Other pieces of useful work done during the year are: the trial excavation of some prehistoric burials at Panjapalli-Parambu near Shoranur, the discovery of a small rock-cut temple of the 11th Century A.D. near Marayur, the study of Vedic chanting and the connected hand poses, and the review of an unpublished Sanskrit manuscript on histrionics and dramaturgy, called " Bālarāmabhāratam". The author of the last-named book was Bālarāma Kulaśekhara Vanchi Bhūpāla, a Travancore king. The work is a valuable one and expounds the art of dancing and gesture somewhat on the lines of the *Abhinaya-darpana* of Nandikeśvara.

Both the reports show that Travancore is a highly valuable field for archæological investigation. It may be suggested that a systematic survey of the State may be made on a regular plan and the information about the finds published in greater detail with more illustrations.

Mr. R. V. Poduval, the Superintendent, and the Archæological Department may be congratulated on the great opportunities for study that they have before them and the interesting beginnings they have made in the years under review. Travancore is a storehouse of South Indian culture and it is to be hoped that her enlightened Government will push on the work of conserving her ancient monuments and publishing authentic information about them.

COLLOID CHEMISTRY. By Arthur W. Thomas. (McGraw Hill Publishing Company, Ltd., 1934.) Pp. viii + 512. Illustrated. Price 24*s*. net.

This volume provides a valuable introductory guide on all phases of colloid chemistry which is treated from the entirely new viewpoint of crystalloidal chemistry, taking into consideration the chemical nature and composition of the colloidal particle. The subject is comprehensively covered by eighteen chapters, each of them being devoted to a discussion of a particular aspect of colloid chemistry. The chapters on colloid optics, dialysis and ultra-filtration and preparation of colloidal solutions, deal with the experimental technique involved in the preparation, purification and study of colloids. The nature and mechanism of dialysing and ultra-filter membranes are discussed in Chapter V which also includes a very informative review of the latest theories on the nature of membrane permeability, and this

important aspect of the subject has been covered in this volume more extensively than in any other book.

A particularly striking feature of this volume is the treatment it has accorded to the two important classes of biocolloids, proteins, and carbohydrates, which will be appreciated by investigators interested in them. A study of these chapters will reveal that the latest developments in this branch, like the researches of Svedberg with his ultra-centrifuge on the molecular or micellar weight of these complex compounds, have been included. There are excellent chapters devoted to a discussion of the nature of micelles, precipitation by electrolytes, electrokinetic phenomena and sorption, aspects of colloid chemistry which will interest not only physical chemists but also others, whose work lies on the borderline between physical chemistry and biology. The fact that information of great technical significance is also to be found in the volume, particularly in chapters on soaps, foams and emulsions, will serve to extend the usefulness of this book into the field of chemical technology. The list of well-chosen and relevant references which will be found at the end of each chapter constitutes a valuable feature of the volume.

INDIVIDUAL HEALTH.—A Technique for the study of individual constitution and its application to Health. By E. Obermer. VOL. I. BIOCHEMICAL TECHNIQUE. By E. Obermer and Molton. (Chapman & Hall, Ltd., 1935.) Pp. xvi+244. Price 15*s*.

The tendency among physicians in the present period of transition from *Pathological* to *Preventive* medicine is to pay attention to the prevention of disease by promoting individual and public health. The physician is concerned with an enquiry into the root-cause of diseases, and he endeavours to maintain the individual in a fit condition, which will enable him to ward off diseases. Obermer proposes a technique of 'adaptational survey' which will enable one to assess the efficiency with which a subject can adapt himself to diet, habit and environment.

The 'adaptational survey' includes a study of heredity and constitution factors, external environmental factors and the reaction of internal to environmental factors. Such a study will give a measure of the functional efficiency and any disorder in the system, strain or lowered resistance can be detected and remedied in the early stages, thus preventing any manifestation of pathological symptoms. The scheme represents the first systematic attempt of individual examination and its success will depend on the co-operation of the members of medical profession and the successful education of the general public on the value of individual health.

The present volume deals with the biochemical technique of the 'adaptational survey' and includes (1) weighing and measuring of food for 24-hour periods, (2) quantitative analysis of normal blood constituents, (3) detailed examination of each urine passed during 24-hour periods, (4) fæcal analysis, and (5) measurement of respiratory metabolism together with the assessment of specific dynamic action of foods. The results of such analyses give a quantitative picture of the dietetic and excretory habits of the subject and permits of an interpretation of endocrine, renal and gastro-intestinal efficiency.

The book is divided into two parts. Part I deals with directions for collection of specimens of ingesta, urine and fæces. Part II deals with the collection and distribution of specimens within the laboratory and also gives a description of a type of laboratory organisation for mass analysis. The methods described in this volume are mainly microphotometric, so that it is possible to carry out a large number of routine analyses with maximum accuracy compatible with minimum quantity of biological material and economy of time. A useful bibliography is appended. This part will prove to be a useful handbook to analysts interested in problems of public health, physiology and pharmacology.

* * *

THE SCIENTIFIC JOURNAL OF THE ROYAL COLLEGE OF SCIENCE. (Edward Arnold & Co., London.) Vol. V, pp. 137. Price 7*s*. 6*d*. net.

This Journal published as a neatly bound book, contains fourteen papers read during the session 1934–35 before the Imperial College Chemical Society, Natural History Society, Mathematical and Physical Society of the Royal College of Science. The fourteen papers are allotted in the order of seven, four and three among the above institutions and include a variety of interesting and important topics.

The opening discourse in the Chemistry Section is on Selenium dioxide: Professor Riley discusses at length the oxidising properties of the dioxide and its application to synthetical processes. Another noteworthy article is that on the chemistry of Gold. In this lecture recent progress in the chemistry of organo-gold compounds are treated from an advanced standpoint. In a short address Dr. Rawling has set forth some chemical themes pertaining to photographic technique and deals in an admirable manner with the curious properties of optically sensitive materials. Professor Ingold's paper on "Aliphatic Substitution" is primarily devoted to a discussion of the modern conception of valency as applied to organic compounds and the kinetics of organic reactions like hydrolysis of esters and so on. The more important subjects included in the Natural History Section are Timber Research, the Significance of Smell and the Origin of Insects. Under Timber Research, an account of the highly useful work that is carried out at the Forest Products Research Laboratory in Princes Risborough is given with a note on the structure and utility of various kinds of timber. The ingenious study on the significance of smell (some speculations on the phenomenology of olfaction) provides eminently readable matter. A clear distinction is drawn between the related sensse of olfaction and vision and the fact that smell plays a predominant role in the study of memory is stressed. The lecture on the origin of insects is at once a lucid exposition of the theory of segmentation in the Arthropoda and an unbiassed criticism of Tillyard's theory put forward in 1931. In the general trend Mr. Reynolds favours the theory proposed by Lankester in 1904. The importance of the gonopore position has not been forgotten as is usual with the theorists. It remains to be seen whether the views set forth here hold their ground against those of the rivals as this highly controversial subject must needs stimulate others to come forward to dispute.

The first paper in the Mathematical and Physical Section is on "Television" which is a highly illuminating and technical address. The disquisition on "Surface Integrals and Fluxes" is of special significance as Professor Fortesque was personally concerned with the deliberations of the subcommittee of the British Standard Institution. Here difficulties of defining the unities of permeability, susceptibility and other fundamental electro-magnetic quantities are at one stroke removed by defining these in terms of undisturbed space. The short abstract of Professor E. A. Milne's paper on the "Expanding Universe" though concise is highly interesting.

The fifth volume preserves all the merits which have characterised its precursors and is on the whole a very representative collection of excellent documents of readable matter.

LES CAROTENOIDES DES ANIMAUX PAR EDGAR LEDERER. (Actualites Scientifiques et Industrielles. Hermann et Cie, Editeurs, Paris.)

The author, being himself an investigator in this field, has published a succinct account of the carotinoids found in the animal kingdom. The book is based on the well-known and classical works of Palmer, Zechmeister and Verne. To begin with, is given a table of the carotinoids of plants to remind the readers of the existence of such pigments in plants. The first two chapters concern themselves with an account of the carotinoids found in several parts of the body of the invertebrates and vertebrates. The third chapter deals with the pigments specific to animals. Biological and biochemical questions are discussed in the last chapter bringing out the relationship between the carotinoids and the related pigments and Vitamin A in mammals, birds, fishes and crustaceans and its importance in medicine. The book provides a useful summary to students interested in the subject. An up-to-date bibliography is appended.

Vol. IV] OCTOBER 1935 [No. 4

CONTENTS.

Rural Development.

IN 1933 the Government of Bombay published an interesting brochure on Village Improvement, which contains a draft scheme for the betterment of the villager and the village,—drawn up by Sir Frederick Sykes. Recently the Government of India have sanctioned large grants to be utilised by provincial governments for rural uplift and last month Mr. R. S. Sathianathan's report on indebtedness in rural areas of Madras was published. At October session of the Representative Assembly of Mysore, Sir Mirza M. Ismail reviewed the progress of work in the advancement of the moral and material well-being of villages under the jurisdiction of his administration. Leaders of public opinion exhort the unemployed young graduates to go to the village and earn a living by serving its population. There are several semi-official and private agencies devoting their time and energies in the work of elevating the rural people. Bright days are ahead for the Indian villages. The universal manifestation of tender solicitude for the amelioration of the conditions of rural life is a phenomenon for which history furnishes few parallels. The general desire to serve the interests of the rural population is a recognition of the fact that this backwardness must retard the progress of the body politic and their insanitary surroundings must all at times be a source of danger to the public health of the village and of the urban areas. It is obvious that the indigence and indebtedness of rural population must react on the general revenues of Government and on the prosperity of industries. The isolation of large sections of population from the centres of administrative activities must account for their backwardness, and the forces which have contributed to the progress of other communities have not enriched the village life. The remedial measures suggested by Governments and others who have investigated rural problems offer hopes of speedy improvement in the lot of the village communities.

It seems to us that the problems presented by people who for ages have lived practically in isolation and have carried on rural occupations in unrelieved monotony will have to be investigated from the psycho-physical standpoint before schemes of reform for their uplift can profitably be discussed. We are not thinking of villages which lie within easy reach of administrative centres. The

physical and mental organisation of the people living from antiquity in the remotest recesses of the country may not easily be amenable to the influence of social and economic reform of governments and unemployed graduates, and the problem of these communities may not be identical with those of the more favoured people residing not far from towns. There is no ethnic homogeneity among the rural population and the success of measures devised for their uplift therefore must depend not on the forces exerted on them from outside, but on their sympathetic reaction to such measures. Are the village people thoroughly dissatisfied with their present condition? In what directions do they demand reforms? How far are they capable of supporting schemes of beneficence by their own unaided assistance?

These questions have been answered by Sir Mirza M. Ismail in his illuminating address. "It is barely eight years since the Village Panchayat Regulation was brought into force; yet in these eight years the number of Panchayats has risen from 8,863 to 11,390, the total revenue collected by them has exceeded Rs. 75,00,000 and they have already incurred expenditure exceeding 45 lakhs of rupees. The raising and expenditure of this money has not been an end in itself, but the means of conferring on our rural population a very large measure of village self-government. The Panchayats in Mysore have justified themselves not merely by the works they have undertaken, the roads they have opened, the drinking water and other wells they have sunk, the village parks laid out and the extension of medical and educational facilities, but also by the spirit of public and local pride which they have engendered. The people have come forward in numerous instances to provide weekly communal labour to improve their villages and it has been calculated that the labour so performed would have cost about rupees 10 lakhs if performed by a paid agency." The contribution of Government to the exertions of Panchayats is even more generous and is reflected in the numerous achievements of government departments which have given the villages more tanks for extending cultivation, cheap electric power for pumping installations, industries and lighting. All these schemes form a coherent part of the policy for the promotion of rural prosperity and their fulfilment is only a realisation of the political faith that "governments are called upon to undertake the control in an increasing measure of the economic life of the peoples entrusted to their care".

Mr. Sathianathan's report on the indebtedness in rural areas of Madras delineates the picture of village population in a totally different colour. The agricultural debt in the province is estimated at rupees two hundred crores, an amount equivalent to 20 per cent. of the landed estates. The report throws light on the extent of the cramping influence exerted by indiscriminate and usurious borrowing, on the development of village activities. In a certain measure it must necessarily curtail the grants for reconstructional operations, since a large proportion of the funds will have to be devoted to relieving indebtedness. The worst effect of this heavy burden is that small holdings have passed into the hands of creditors who are unable to continue the agricultural operations and the larger holdings suffer from absentee landlordism capable and willing to advance credits more in the way of investment than as a means of stimulating agricultural operations. The rural problems in a presidency such as Madras must be too complex and difficult to permit of easy solution. Debt rarely fructifies in the hands of the borrower, least of all in those of the agriculturist. Debt Conciliation Boards, if instituted and worked in the spirit in which the Bill for their formation is conceived, the cultivator may find some relief but there is nothing to prevent him from raising fresh loans. The scheme of controlled debt to which reference is made in the report, the essence of which is to provide loans of money and realise them in kind by periodic and expert supervision of cultivation, may assist in keeping the ryot on his land which is undoubtedly a great step in the general movement of rural uplift. Sir Frederick Sykes points out that debts are generally contracted by habits of extravagance and by adherence to expensive customs which the ryot has no courage to withstand. The tendency to take trivial disputes in suits to law courts involves the village population in appalling waste of money, and litigation is more often a fatal enterprise to the villager. The problem of rural reconstructions in large presidencies has a multi-lateral phase and simultaneous attack on all the fronts is proposed by governments and political leaders and the fruits of victory will be

permanent only if the village population actively join the forces initiated for their improvement.

It seems to us that there are certain other ferments stirring village life which must militate against the success of the efforts of even governments to regenerate rural welfare. The people who live in villages not far from the towns come into almost daily contacts with the attraction offered by urban life. Saints and philosophers find it hard to withstand them; the Indian villager has neither the fortitude of the one nor the discipline of the other. The increasing dazzle for town life overpowers him. The expansion of industries offers him reasonable security of engagement, regulated hours of work and protection of labour unions which supervise his education, health and comforts. He welcomes relief from anxieties inherent in his profession, which control over meteorological conditions alone can remove. The large engineering works initiated by the governments, business offices and banks and expansion of places of public amusements and restaurants are slowly absorbing the rural population. As the towns expand industrially and economically the villages naturally contract. How to arrest this depletion of villages is a question now receiving anxious public consideration.

The farmer may be educated. We may provide him with modern implements, credit and expert advice. Facilities may be created for recreation and subsidiary occupations. Every inducement which may be expected to make him happy and contented to remain in his place and cultivate the land can be offered. He finds that his output is governed by new economic laws from which he suffers as acutely in the years of scarcity as in the years of plenty. Agricultural industry is individualised and it is not a syndicate. Without resources of finance and collective power such as well-organised business can always command, agricultural communities being industrialists are confronted with fluctuation of commodity prices arising from "economic depression," "exchange ratio," "tariff rules" and all other phrases and traps. However, the phenomenon of suffering in the midst of plenty is peculiar to modern economic civilisation. The remedy seems to lie in agriculture striking up a new friendship with chemistry for profitable utilisation and disposal of surplus produce. The country which knows no waste is bound to give a new lead to civilisation. The key to rural prosperity is not external padding but research on waste. Science has created poverty amid plenty and science alone can save. It is hard to make the public realise that, but for the vested interests which have grown so immensely round our social and economic problems, science could solve practically every difficulty which confronts governments and private organisations in promoting prosperity and in improving social standard.

The process of recruiting the gifted members of the rural population and other industrial communities to public service may satisfy the principle and policy of communal representation, but it must necessarily impoverish the economic power of even the favoured families. Sir Frederick Sykes pointed out that "we must discard the idea that village betterment depends entirely on forces from without—on action independent of the will of the villager." Who is to supply this will to progress without which all schemes for the spread of material welfare and greater contentment among the agricultural population must be futile, particularly when its educated and forward members are alienated from their traditional occupations and new castes are formed having neither opportunity nor inclination for the scientific study of the development of rural occupations? When those who can revitalise the resources and energies of village life are steadily drafted for other services, the helplessness and crudity of others left behind tend to be perpetuated and the moment we withdraw external assistance, the confusion must worsen the situation. The present position in the villages is a result of the emigration of the more capable individuals of the rural population to town, attracted by inducements for bettering their prospects, held out by government service, industries and business organisations. Education has produced in all communities a thirst for soft appointments in Government Departments, but has not encouraged the spirit of service to the community and pride in family occupations.

Modernisation of Indian villages is inevitable and in order to sustain the improvements and carry it further, it is necessary that the educated young men who have been hitherto looking forward for Government service, should acquire special qualifications for rural reconstruction. An untrained

young man may turn his back on the work he has undertaken on encountering difficulties and disappointments. In several respects the problems of village improvement are technical and their satisfactory solution depends on the aptitude and training which the young men possess. It seems to us that the work of elevating the rural population will be successful if governments could organise special courses of instruction in moral sciences in the universities for the benefit of the people whose prosperity and contentment are the safest insurance of peace and progress of the country, and for the relief of unemployment among young men whose condition engages the anxious consideration of the public and Governments.

Agricultural Research in India.

THE annual report of the Imperial Council of Agricultural Research for the year 1933–34 which has just been published, is a document of absorbing interest, not only because of the large number of special schemes, both scientific and economic, sanctioned by the Council and in progress, but also because of the many more important schemes which are planned or foreshadowed. The large increase in the output of scientific research in Agriculture is an outstanding feature of the progress of scientific research in the country and the Research Council can already claim credit for much of this activity; indications are, as a matter of fact, that it will soon be the greatest single factor tending to the progress of agricultural research, thanks to the liberal grants of money voted by the Central Government for this purpose. The report refers to a temporary cessation of the annual grant owing to financial stringency which has prevented the Council from going forward at the initial pace and which has necessitated the holding up of many a sanctioned scheme. It almost looks as if it was a case of "first come, first served" and that many new schemes had no chance of being considered. A special grant of Rs. 5 lakhs towards the end of the year somewhat improved the situation, though even with this further grant, schemes already approved and costing about Rs. 11 lakhs have had to be kept in abeyance. The list of the schemes already in progress and the amount set apart for each is interesting reading, if at least to show what a vast field remains untouched. Thus out of the 41 schemes in progress, 18 relate to the sugar industry and absorb Rs. 25 lakhs out of a total of about Rs. 45 lakhs. Schemes relating to rice research absorb about Rs. 11 lakhs, and those relating to locust research cost about Rs. 4 lakhs, so that these three subjects alone take up about 90% of the total grant. One need not grudge to the sugar industry which has within the last five years undergone phenomenal development and added largely to the material prosperity of the country as a whole and of the agriculturist in particular, this large measure of help; nor to subjects like rice research and locust research, the substantial proportion they receive by reason of their great importance, but when one compares the bare 10% of the grants which remains for meeting the needs of the large variety of crops and of much-needed development in both crop and animal husbandry, the anomaly of the situation becomes rather striking, and the necessity for a substantial increase in the grants available assumes additional urgency. It is true that much water has flown under the bridge since the period covered by the report and that money has been voted for a number of new schemes, the most notable among which is the one relating to the important subject of the marketing of agricultural produce and the appointment of a chief marketing officer. Furthermore, the needs of one major crop *viz.*, cotton, are being met largely by the mill industry itself through the cotton cess fund, administered by the Indian Central Cotton Committee; a similar cess assists the lac industry; the sugar industry is also in a manner helping itself through the excise duty now being levied; the report, moreover, refers to a proposal for levying a cess on the export of oil-seeds for affording funds for research on the development of the oil-crushing and allied industries in the country. If this latter proposal should materialise, it will mean that one large group of agricultural produce will be meeting its requirements for funds from its own resources. It should, therefore, be possible for the Government of India to set apart substantial sums for research on other important branches of agriculture. As a matter of fact, some of the schemes already sanctioned, such as the marketing inquiry, will inevitably call for a much larger expenditure before long, as each survey discloses lines for suitable practical action.

The Report refers to the formation of

three separate Standing Committees for animal nutrition, cattle-breeding and dairying and also to steps taken for the investigation of important cattle diseases, during the year. The latter certainly demands much greater attention and one can hardly think of a more fruitful field for the Council's help. The livestock industry in the country is already a huge one and as the years go by, is bound to assume still greater importance from the point of view of increasing the earnings of the ryot and of improving the nation's food supply; but one of the greatest handicaps to progress is the prevalence of disease which threatens the industry on its present scale itself; while expansion or improvement in respect of breeds whether it be cattle, sheep or poultry is practically out of the question. The veterinary staff in the provinces has neither the time nor the facilities for anything beyond the routine of a general practitioner, and such research facilities as exist at the Muktesar Institute and in some of the Veterinary Colleges and Serum Institutes are disproportionately inadequate for the needs of the country. A Central Institute for this purpose, well-equipped and staffed, is a crying need and forms a legitimate demand upon central revenues. This, of course, does not rule out assistance to the provinces and existing institutions conducting researches such as the present provision of Rs. 2 lakhs for the investigation of tuberculosis and Johne's disease. We wish the scheme of sheep breeding, referred to in the report, took precedence over some others, or, was accorded special treatment and proceeded with, for the possibilities are admittedly great and the subject has been relegated to the background for a very long time. As it is, a sum of Rs. 85,000 is said to have been sanctioned for a scheme which, however, had to be kept in abeyance for want of funds. A beginning is said to have been made in the matter of registration of pedigree stock of dairy and draft cattle; a revised and uniform classification of cattle for purposes of the quinquennial cattle census has been approved by the Advisory Board, which is an improvement on the present form; a recommendation fixing a three years' course with F.Sc. as an entrance qualification in the Veterinary Colleges and a curriculum suitably revised for the course was also approved by the Board, in the Animal Husbandry Section.

In the section of crop industry, work on sugarcane occupies, as already indicated, the most important place. A chain of eight research stations in Upper India and three located in Bombay, Madras and Mysore have carried on work relating mainly to the breeding and testing of superior varieties and incidentally to other aspects of cultivation such as, manuring, irrigation and methods of jaggery making. Work on the improvement of the indigenous methods of sugar manufacture has received considerable attention as likewise the methods of jaggery making. In the face of the competition from sugar made in large-scale factories whose efficiency is being rapidly improved we doubt if the old-fashioned *Khandsari* sugar has any chance and if it is worthwhile spending money over improvements in the methods. The case of jaggery is however quite different, for not only does this product come in as a class by itself and distinct from sugar but it forms about the only outlet for the cane crop in many parts of the country which for various reasons cannot be thought of for sugar manufacture on a factory scale. Better extraction, cheapening the cost of manufacture and improvement in the appearance and keeping qualities of the jaggery, will all make it a more remunerative proposition, and afford scope for considerable research work. We would also add that the prospects of manufacturing raw sugar or refining crystals in preference to jaggery in some at least of the jaggery-boiling centres, deserves to be investigated. The appointment of a geneticist for the cane-breeding station at Coimbatore and the strengthening of the mycological staff at Pusa for the investigation of mosaic and other diseases of sugarcane during the year, are noteworthy, as likewise is the approval by the Board of a scheme for the study and control of insect pests on sugarcane. Knowing as one does how serious the position is in these matters, a more welcome feature of the year's work on sugarcane can hardly be thought of and we hope this pest control scheme will be taken up without further delay. The enquiry into the cost of production of crops in the sugarcane and cotton growing tracts in India has not been undertaken any too soon and one can say from personal knowledge that the results are sure to throw a good deal of light on a subject of great importance in the economics of agriculture on which opinions at present are vague and often contradictory. It is a matter of

gratification that the Council has boldly embarked upon this inquiry notwithstanding its cost and despite perhaps the opinions of doubting Thomas's about its value.

Research on rice occupies the pride of place, judged by the expenditure sanctioned, among the other schemes. It is a comprehensive all-India scheme costing Rs. 11 lakhs, spread over a period of five years. Work, however, seems to have related mainly to the breeding and testing of varieties which most provincial departments are already engaged upon, but the grant is said to have enabled the departments among other things, to widen the range of varieties handled. We may, perhaps, single out the work in Burma for special mention, for it relates to the development of strains of rice suitable for the English and European markets and leading therefore to an expansion in the foreign trade in rice. The period of five years is too short for the work in view, and we feel certain, that the need for continuing the scheme will have to be faced. While on the subject of foreign markets for Indian produce, we may draw attention to the collection and circulation of information by the Council during the year regarding the quality of the different kinds of produce, notably oil-seeds, which enjoy a preference in the United Kingdom markets under the Ottawa agreement, which will enable them to compete with non-empire produce and will make the preference really operative. We are glad that as an all-India organisation, the Council has been fully alive to the importance of this matter and is closely watching the working of this commercial agreement in the interests of Indian agriculture.

It is rather disappointing that in respect of tobacco where the scope for improvement with a view to meeting the local demand for cigarette tobacco and also producing enough for an export trade is very considerable, the Council could not do more than appointing another committee. We hope this committee's work will lead to practical action very soon, among which we may suggest suitable financial help to provincial departments undertaking the cultivation of the special varieties and the curing and conditioning of the produce according to up-to-date methods.

Among the minor activities of the year, we may refer to the subject of statistical studies in agricultural research and the help afforded by the Council in the training of agricultural officers in these methods. The field trials and the interpretation of the results stand to gain in accuracy and already the effect of the training is noticeable in the studies and publications of many of our experiment stations. The initiation of studies in agricultural meteorology is another important development to the credit of the Council and considerable work has been done especially in correlating crop yields to meteorological data and in the evolving of suitable instruments and of technical methods. Weather Bureaux elsewhere have been of such great assistance to farmers that we can expect our own organisation also to play a similar rôle, provided the staff is strengthened so as to secure co-ordination with the existing meteorological stations in the different parts of the country.

It will be impossible to refer even briefly to all the schemes and other activities of the Council. The oil technology work and the work on the utilisation of molasses at the Harcourt Butler Technological Institute, the work on the utilisation of town refuse and farm waste for manure at the Indian Institute of Science, potato breeding on the Nilgiris, inquiry into the trade in cocoanuts and cocoanut products, locust research, water hyacinth control, dry farming schemes, goat keeping, 'quality' in crop investigations, malting of cholum, fruit research schemes, research on virus diseases, are some of the schemes referred to in the Report. As already indicated, however, nearly all the schemes have been going on only for short periods and some have hardly begun. Moreover the Report itself, latest as it is, appears to be very incomplete; so rapidly have the activities of the Council been expanding and so many are the new schemes taken up since the period covered by the Report. The Council is gradually approximating in scope and organisation to the Federal Department of Agriculture in the U. S. A., and we have no doubt that the Council will succeed in doing as much for our agriculture as the U. S. Department is doing for the American farmer.

Poverty amidst Plenty.

THE paradox of Poverty amidst Plenty has become almost a platitude by iteration. Nevertheless the conscience of thoughtful people continues to be disturbed. Why is food thrown into the sea when

millions are ill-nourished? Why is cotton ploughed into the soil when millions are ill-clad? There are those who blame the discoveries of modern science for this trouble, the means of production have vastly increased while distribution has lagged behind. The problem would seem indeed to be largely a question of time-lag. Part of the world is living mentally in the age of the bullock cart, part in the age of the aeroplane. Thus the financial world is still largely governed by the ideas of a pre-scientific era and is therefore ignorant of the implications of modern science. The scientific worker, on the other hand, is little concerned with the world of finance and the possible results of his own discoveries, in relation to the public welfare.

It is satisfactory, therefore, to note that at last the scientific world is waking up to the need for the realisation by scientific workers of their responsibility for the wider aspects of human welfare, lest science itself shall come under condemnation. A recent letter of protest against the misuse of scientific discovery has appeared in the press bearing the signature of the President of the Royal Society and a number of other distinguished names. Sir Richard Gregory speaking recently at a Rotary luncheon at Norwich made an eloquent plea for the right use of the gifts of science, and looked for the time when science would no longer be thought of as a destroying angel but as the herald of a more abundant life.

Following a recent discussion at Oxford on "Academic Freedom", reported in the August number of the *Journal of the Institute of Chemistry*, a resolution was passed to set up a Committee with the object of seeing that so far as possible science should be used only for the benefit of humanity. Of even greater significance than protest and eloquence is the fact that a representative body of engineers and scientific workers of the British Science Guild have formed themselves into a group to study the problems of modern economics and these studies have resulted in the publication of a highly valuable document entitled "First Interim Report on Schemes and Proposals for Economic and Social Reforms". No fewer than 24 proposals have been carefully studied and their essential features tabulated. Among these proposals may be specially mentioned :—

Sir Basil Blackett's "Planned Money",
Proposals of the Communist Party,
Conservative Party Proposals,
Douglas Social Credit Proposals,
The Proposals of Silvio Gesell ("Free Economy"),
The London Chamber of Commerce Proposals,
Professor Soddy's Proposals, and
The Proposals of the Continental Committee on Technocracy.

The British Science Guild have published other pamphlets of scientific and economic interest among which may be mentioned "The Electron Liberated: Its Industrial Consequences", by Clifford C. Paterson, O.B.E., M.Inst.C.E., M.Inst.E.E., and "Human Biology and Politics" by Professor J. B. S. Haldane, M.A., F.R.S.

This activity among scientific workers may help to lay a true foundation for a new world where every hungry mouth has enough to eat, every capable hand enough work, where exploitation in the name of business is unknown and where peace and sufficiency reign supreme.

The appeal made by Dr. Fowler in his recent paper entitled "Energy and Economics" which appeared as a supplement to the May number of *Current Science*, calling for greater attention on the part of scientific workers to the problems of modern economics, has our warm support, and we hope to return to the subject in a later issue.

Rajasabhabhushana Sir Chandrasekhara Venkataraman, Kt., F.R.S., N.L.

Director, Indian Institute of Science, Bangalore.

HIS Highness the Maharaja of Mysore was graciously pleased to confer the title of "Rajasabhabhushana" on Sir Venkataraman at the recent Dasara Durbar held in Mysore. We have great pleasure in congratulating Sir Venkataraman on the glittering decoration bestowed on him. Palace honours are usually reserved for officers rendering distinguished service to the State, and the titles connote the merits and accomplishments of recipients. But in the case of Sir Venkataraman, all laurels become his brow. His Highness's generous act will be widely appreciated.

Geochemistry and Biochemistry.

By Prof. A. P. Vinogradov.

(*Biogeochemical Laboratory of the Academy of Sciences, U.S.S.R.*)

I.

UNTIL quite recently, it was generally believed that organisms—plants and animals—consisted of a very limited number of chemical elements.

This view has, now, to be abandoned, since 60 chemical elements have been discovered in one or the other of the organisms ; it is, perhaps, easier to name those chemical elements which have not been found in organisms or about which indications are unreliable. The chemical elements not yet discovered in organisms may be referred to five groups : (1) the radioactive elements Pa, Ac, Po and the numerous radioactive isotopes* ; (2) the rare-earth metals—Tl, Eu, Gd, Tb, Dy, Ho, Er, Tm, Il and Lu ; (3) the inert gases He, Ne, Kr, X ; (4) the elements of the platinum group : Ru, Rh, Pd, Os, Ir, Pt § ; and (5) of all the other chemical elements : Te†, Zr†, In, Ta, Hf, Ma, Re, 85† and 87†.

This list shows with sufficient conclusiveness the present position. For the majority of the chemical elements named, there are yet no simple and sufficiently sensitive and accurate methods of determination. It may be conjectured that these elements may be found in organisms only in negligibly small amounts.

Nevertheless, the constant finding of one or the other chemical element, often in small amounts (in thousandth, millionth and lesser parts of a per cent. ; they may, therefore, be called microelements), in the tissues of organisms, was not a convincing indication for biochemists, of the important physiological part of those "traces" of microelements. Scores of years were required after I, Cu, Mn, B and many other microelements were found in organisms, to recognise their important rôle in physiology.

The exceptional interest of the question of the physiological rôle, in particular, of microelements present in the tissues of organisms, arose recently among biochemists (physiological function of Cu, F, B, etc.) and especially among agrochemists (importance of B, Cu, I, etc. for plants).

As in the past, the many-sided researches in this direction, which are conducted by various specialists, physiologists, biochemists, chemists, agrochemists, mineralogists, etc., are being carried out along different paths, and pursue quite different objects. Owing to this there has occurred a certain break. The unique common phenomenon—the process of shifting matter, the *biogene migration* of atoms in the complex *indissoluble system —soil—soil solution—plants—animals,*— was lost sight of by these investigators.

II.

Not less persistently, is the view held that the *chemical elementary composition of organisms* does not represent any differences as to species, genus, etc. ; that it is not constant and is subject to considerable variations. In other words, we cannot definitely consider it proved, that the chemical elementary composition of organisms is a specific character. It must be noted, however, that from this point of view, the subject has not been systematically investigated.

The study of the chemical elementary composition of living organisms has been, in a way, the special interest of the physiologist, biochemist, agrochemist and mineralogist. The importance of the problem is only being recognised at present. And, nevertheless, many scores of thousands of analyses of various organisms made during a period of more than a century, by agronomists, biologists and mineralogists, on closer examination, contain direct proof of special features, and of a certain constancy in the chemical elementary composition of species.

For instance, the differences in the contents of phosphorus and nitrogen in plants and animals are very well known. Among organisms are known to us numerous species,

---

* Besides MsTh, see works from our Laboratory—V. Vernadsky, B. Brunowsky and Kunaseva, *Compt. Rend. d. Sci. Acad. Paris*, 1933, T. **197**, 1556.

§ It is of interest to note that Ge was discovered in organisms recently by V. M. Goldschmidt within the ranges indicated in the curve. Into the maximum enters Ru, one of the elements of the platinum group, which forms soluble compounds more easily than others. In the smallest amounts is probably found Th.

† Indications not checked, but their occurrence in organisms is known.

which concentrate definite chemical elements in considerable amounts. We are familiar with the division of plants into the calcareous and siliceous ones. Among the latter are, for instance, the grasses, sedges, horsetails, and diatoms. We know perfectly well the typical iron-organism (also that of manganese, sulphur, etc.); the halophytic flora (Na and Cl), numerous hydrophites, which collect considerable amounts of aluminium ‡ (marine and fresh water algæ, many aqueous phanerogamous plants—monocotyledons, bacteria, etc.), and the like.

In relation to many chemical elements it might be possible to indicate typical organisms—concentrators. It is possible to easily discover the peculiarity of the chemical elementary composition of definite species of living organisms by comparing the composition of different plants for which numerous determinations have been made, especially for the composition of their seeds. In the Biogeochemical Laboratory of the Academy of Sciences of USSR investigations were made on the chemical elementary composition of 13 species of *Acridiidæ*, collected from various localities during a period of three to four years. These data have shown a complete stability of the composition of *Acridiidæ*, its resemblance to proximate species and very great distinctions from the chemical composition of other insects. Sometimes, in animals, the definite occurrence of only one chemical element acquires a specific character. For instance, investigation of 20 species of ants has shown us, that the species of the family *Camponotinæ* contain Mn of an order N. 10^{-2} per cent. but species of the family *Myrmicinæ* of an order N. 10^{-3} per cent., while the more primitive family *Ponerinæ*, as it seems, contains still less Mn. Another instance: ascidians are rich in vanadium. They are typically vanadium-organisms. Nevertheless, as we have shown, not all the species of ascidians concentrate vanadium. Species from the families *Ascidiidæ*, *Cionidæ*, *Botryllidæ* and some others concentrate vanadium, whereas the majority of species from the families *Tethyidæ*, *Melgulidæ*, *Synoicidæ*—do not contain any marked amounts of vanadium. Similarly, among the families and genera of living organisms rich in vanadium, manganese, iodine, copper, etc., are distinguished species exceptionally rich in one or the other chemical element. The number of such instances may be multiplied. We have quoted them in our work on the chemical elementary composition of marine organisms.

Fluctuations observed for the chemical elementary composition of organisms may be accounted for as being due to age, season, sex and ecological factors. The individual fluctuations of the chemical elementary compositions recall similar fluctuations of the morphological characters in organisms.

Thus, there certainly exist typical differences in the composition of definite species, genera and other taxonomic units.

The chemical elementary composition of organisms is a species character.

III.

The chemical elementary composition of organisms or the finding of one or of another element in the tissue of these organisms has been studied by biochemists, as a rule, outside its natural environment—the biosphere.

Between the environment and the organisms there occurs, uninterruptedly the exchange of matter—the environment and the organisms are closely connected by the common history of the atoms of the chemical elements. *Living matter* (totality of all organisms) during more than one million years has shown enormous geochemical activity, by concentrating various chemical elements, by playing a considerable rôle in sedimentary rock formation. In the chemical composition of each organism we encounter the expression of a definite geochemical part played by the given species of living organisms. From a geochemical point of view, some *geochemical functions* are inherent to all organisms—in some the calcareous geochemical function predominates, in others the siliceous or phosphate one, and so on; and, finally, several such functions may take place together. The chemical elementary composition of organisms and therefore the range of participation of the organisms in the biogene migration of the chemical elements in the biosphere cannot be left without attention when studying the geochemical laws of the distribution, combination and migration of atoms within the earth's crust. For the first time, the *biogeochemical* ideas indicated were stated with exceptional vividness by Prof. V. I. Vernadsky. From that moment the question of the chemical elementary

‡ Contemporary *Licopodiacea* are rich in Al. Probably the fossil *Lepidodendron*, which are closely related to the latter, were also rich in Al. Their coal is rich in Al.

composition of organisms acquired a full scientific value. And the closer we approach it, the more obvious becomes the fact that the general geochemical laws, governing the distribution and combination of the chemical elements in the earth's crust govern also all living matter.

IV.

We have got accustomed to the biogene migration of atoms between organisms and environment, which is occurring in the biosphere during scores of thousands of years. We do not notice this close, indissoluble, unchanging (within historical time) connection between them. It becomes manifest as soon as a disturbance occurs.

We often come across such biogeochemical phenomena.

The *deficiency* or *excess,* as compared with the usual presence in the environment, for instance in soils, of some definite chemical elements, owing to the peculiarity of the geochemical history of the given locality, calls forth, over tremendous areas, a change of the qualitative and quantitative morphological composition of the soil cover and of the animal world connected with it. It is well known, for instance, that the deficiency of Ca, P, (for instance, in soils originating from granite) calls forth a disturbance in the composition of the flora. Thus, for instance, the grasses of the Savannahs and steppes experience phosphate hunger, etc., and in their turn the steppe animals, cattle from the pastures, become sick because of deficiency of phosphorus (and lime) (inflammation of the bones, "brittle bones"). Those phenomena are observed also on cultivable soils throughout the whole world. The deficiency of Fe (and Mn) in the soil leads to sickness of both plants and animals. Perfectly well known is the spread of endemic goitre among men, cattle, birds, fishes, etc., in localities with a deficiency of iodine in the soil, drinking water, etc. At present, in many countries (Holland, Germany and others) are known soils demanding Cu for the successful growth of crops. The absence of Cu in the feed, appears to cause in cattle a special sickness (licking disease). Many soils, as it has now become evident, demand for the normal growth of some crops—leguminous plants, flax and the like—a definite ınt of boron. On the contrary a ·xcess of one or another chemical soil, leads to similar *geo-* ·es occupied by peculiar *biogeochemical endemies.* We know of Se, As, and other "poisonings" of some soils. The excess of F in soils, soil waters, in drinking water in many countries—U. S., Algiers, Tunis, and others—causes an endemic disease of man, the so-called "mottled enamel", and so on. Much in this direction we still do not know. Similar biogeochemical endemies connected with the presence in the soils of Zn, Al, serpentine and others have a lesser range. All this leads to the formation of peculiar variations in some definite plants from these soils. It seems to us that the existence of regions (soils) with an unusual content of some chemical elements, forming geochemical provinces or separate "spots", should prove a kind of hindrance for the spreading of definite species of organisms.

Therefore, such geochemical provinces have the property of a selecting and transforming factor for organisms. In the process of their life and evolution, plants and animals in their turn (in a geological sense) lived on a definite substratum which formed only one of the stages.

Thus, it seems to us, that in each *species of organisms are concealed the chemical characters of their origin.*

The study of the chemical elementary composition of organisms from a geochemical point of view helped us to arrive at some general conclusions. The average chemical composition of living matter may be graphically expressed in the form of a curve (see Fig. 1). Comparison with similar curves for the distribution (frequency) of *atoms* in the soils, earth's crust, living matter, etc. shows that at their basis lies one general law of quantitative distribution of atoms. However, they differ in details. Each of the paragenetic spheres (living matter—biosphere) is characterised by its peculiarities. We see from the curve for the distribution of chemical elements in the living matter that: (1) the number of atoms of chemical element in the living matter is in inverse proportion to its atomic number (atomic weight). In other words, the chemical elementary composition of the living matter, as a whole, is definitely related to the number of charges on the nuclei (protons). (2) The curve shows a regular periodicity (6 and 8) with definite maxima and minima, representing certain regular deviations from the hypothetical inclined curve (which may be traced from H to U). Periodicity for the number of atoms in living matter is

Chemical Elementary Composition of Living Matter (in per cent atoms).

◧ ◐ —qualitative ,,
□ ○ —probable ,,

Fig. 1.

accurately observed within the ranges of the first 50–60 elements, for which experimental data exist. The curve can be extended further; few data exist for the remaining chemical elements—Au, Hg, Ra, Th, etc. (3) The chemical elements which occur in maximal quantities play the chief part in the composition of organisms. In relation to those elements numerous organisms—concentrators,—are known. They are especially varied and numerous among the representatives of ancient groups of organisms (*Tallophyta*, *Protozoa*, etc.). The elements, occurring in minimal quantities, are not concentrated by organisms. From a geochemical point of view those elements—inert gases, Hf, Zr, Th, Rh, Se, partially Ti, and others—are characterised by a nearly complete absence in them of the capacity to form soluble compounds (in soil, etc.)* in natural conditions.

Thus the range of deviation from the straight inclined line (appearance of maximum and minimum) for different elements depends on the chemical properties of atoms (outer electrons of atoms). Therefore, those maxima and minima occurring in definite species find places on the curve and although they may vary in the position, they nevertheless do not disturb the general periodicity of the curve.

In the future a more detailed study of the distribution of the chemical elements in the organisms from a geochemical point of view shall allow biologists, physiologists, agronomists, geochemists, etc., to tackle important problems of natural science using a common scientific language.

Some Recent Work on Isotopes and Hyperfine Structure of Spectral Lines.

By Prof. B. Venkatesachar, M.A., F.Inst.P.
Department of Physics, University of Mysore.

THE chemical and physical properties of an element are in the main determined by its atomic number. All elementary substances having the same atomic number but different mass numbers constitute a group of isotopes and occupy the same position in the Periodic Table. According to this definition of an isotope, H^2 (deuterium) and H^1 (ordinary hydrogen) are to be considered as two isotopes of hydrogen. Here, however, the difference in properties between the two isotopes is more marked than with other isotopes. This difference results from the pronounced inequality in the masses of H^2 and H^1.

The isotopic constitution of elements has been investigated mostly by Aston, Dempster and Bainbridge with the aid of mass spectrographs, each using an instrument of his own design. In all these instruments a mass ray containing charged atoms of the element has to be produced. For the production of such rays the existence of suitable volatile compounds frequently becomes a necessary preliminary condition. The search for such compounds has retarded the successful isotopic analysis of several elements. Of such elements palladium, iridium, platinum and gold stand prominent.

HYPERFINE STRUCTURE OF SPECTRAL LINES.

Spectral lines which appear single in spectroscopes of low resolving power often exhibit a structure when instruments of high resolving power are used, *i.e.*, in place of a single line a group of lines with small differences of wave-lengths is seen. Pauli was the first to make a fruitful suggestion to account for the hyperfine structure. In the light of subsequent theoretical development the suggestion of Pauli is equivalent to attributing a spin to an atomic nucleus: the interaction of the resulting nuclear magnet of comparatively small magnetic moment with the rest of the atom considered as a magnet would have the effect of splitting multiplet levels into bunches of close levels, the resulting transitions giving rise to the observed hyperfine structure. Taking I to represent the nuclear spin moment and J, the resultant mechanical moment of the rest of the atom, there will result $2I+1$ or $2J+1$ hyperfine levels according as $J>I$ or $I>J$. It is found that only isotopes with odd mass numbers have a nuclear spin, the even isotopes having zero spin moment. Though the spin of the even isotopes is zero they do not give rise always to coincident spectral levels. The separation of the levels in any case due to the even isotopes is called even isotopic displacement (Fig. 1). In the case of an odd isotope for purposes of evaluating isotopic displacement the centre of gravity

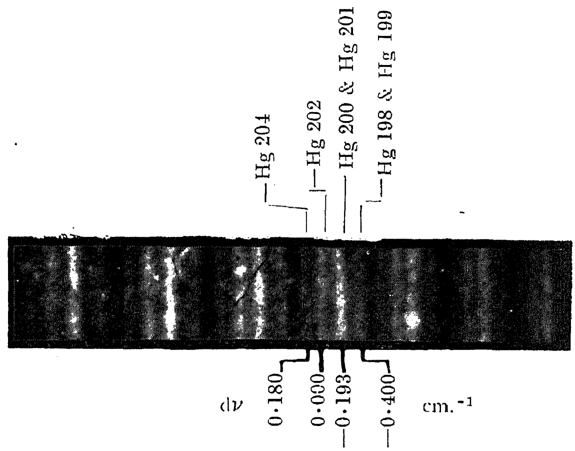

Fig. 1.
Structure pattern of Hg II 2262·33Å ($5d^9\,6s^2\ {}^2D_{5/2} - 5d^9\,6s\,6p\ {}^2D_{5/2}$) showing isotope displacement.[1]

of the hyperfine levels is taken. This displacement of levels has an origin different from that due to a change in the mass of the nucleus in the expression for the Rydberg constant, the latter may be called a pure mass effect. It may be remarked that the doubling of the lines in the atomic spectrum of a mixture of H^2 and H^1 has its origin in the variation of the nuclear mass, in other words it is a pure mass effect.

In the laboratory of the author investigations on the hyperfine structure of the lines of the elements palladium, iridium, platinum and gold were undertaken with a view to determine their isotopic constitution and the nuclear spins of the odd isotopes. Sufficient theoretical and empirical information regarding the nature and origin of the hyperfine structure to enable one

[1] Venkatesachar and Sibaiya, "Hyperfine Structure of some Hg II lines," *Proc. Ind. Acad. Sci.*, 1934, **1**, 8.

to make such determination is available provided the structure patterns can be photographed without complications arising from self-reversal. Since the significant lines for this purpose arise from transition to the ground-level or levels very near it, avoidance of self-reversal becomes a matter of some difficulty. The following arrangement of apparatus has been evolved for the purpose as the result of a considerable amount of investigation.[2]

DESCRIPTION OF APPARATUS (Fig. 2).

The hollow cathode employed in this investigation is a double-walled copper cylinder hard-soldered at both ends with the inside hollow about 1 cm. in diameter and 6 cms. in length. Inlet and outlet tubes are provided so as to maintain a continuous flow of water in the space between the two cylinders during excitation. On to the shoulders cut in the outer copper cylinder are fitted pyrex glass tubings with a quartz window on one side and a ring anode on the other. The metal glass joint is rendered air-tight by Apiezon sealing wax and due to the continuous flow of water in the hollow cathode the joint continues to be air-tight under all conditions of discharge. The apparatus is set up *in situ* with a thin cylinder of the metal under investigation fitting tightly in the hollow cathode. The apparatus is next exhausted with a mercury diffusion pump backed by a Cenco Hyvac pump. The backing pump is then cut off and the activated charcoal is cooled by liquid air contained in a triple wall Dewar cylinder. Helium is now let in slowly, further purification being effected by its passage through the liquid air-cooled charcoal. When the required pressure of helium (about 1 or 2 mms. of mercury) is reached the supply is cut off. Requisite amount of helium is thus allowed to circulate continuously through the hollow cathode by the operation of the diffusion pump. The repeated passage of helium through the liquid air-cooled charcoal maintains its purity. A direct current dynamo of 1 kilowatt capacity is employed to send a discharge through the hollow cathode. For the excitation of the arc lines a discharge current of 150 mA at 1500 v. is found satisfactory. At this stage the hollow cathode glow is intense and is accompanied with little or no positive glow. The discharge conditions can be maintained steady for hours together by replenishing the liquid air from time to time.

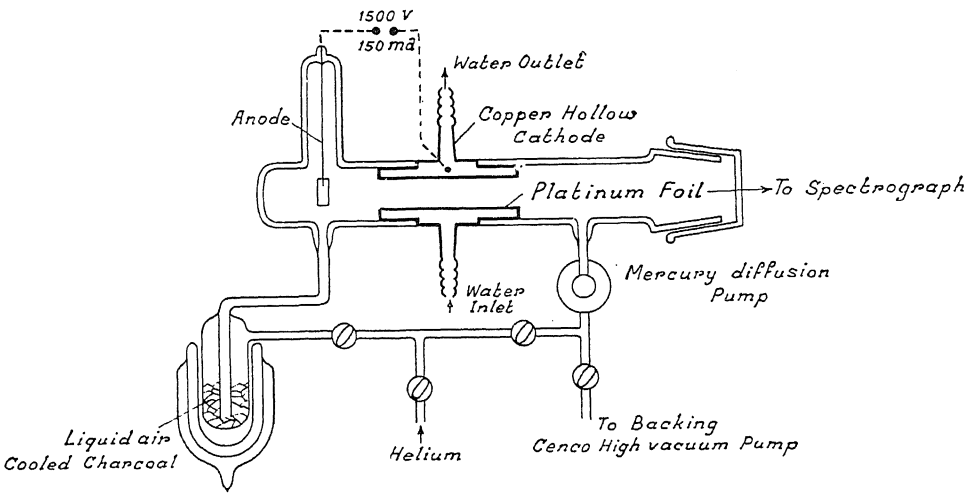

Fig. 2.
Hollow Cathode Source.[2]

The hollow cathode glow is concentrated on a Hilger Lummer Gehrcke plate of quartz (3·45 mms. thick and 20 cms. long) by means of a quartz lens carrying a double-image prism. One of the images is cut out and the light of the other, with its electric vector parallel to the plate, passes through. The pattern is focussed by a quartz achromatic lens on to the slit of a Hilger E1 spectrograph with a quartz train. The hyperfine structure patterns of the arc lines are

Arc lines of platinum and iridium analysed. (Not to Scale.)[4]

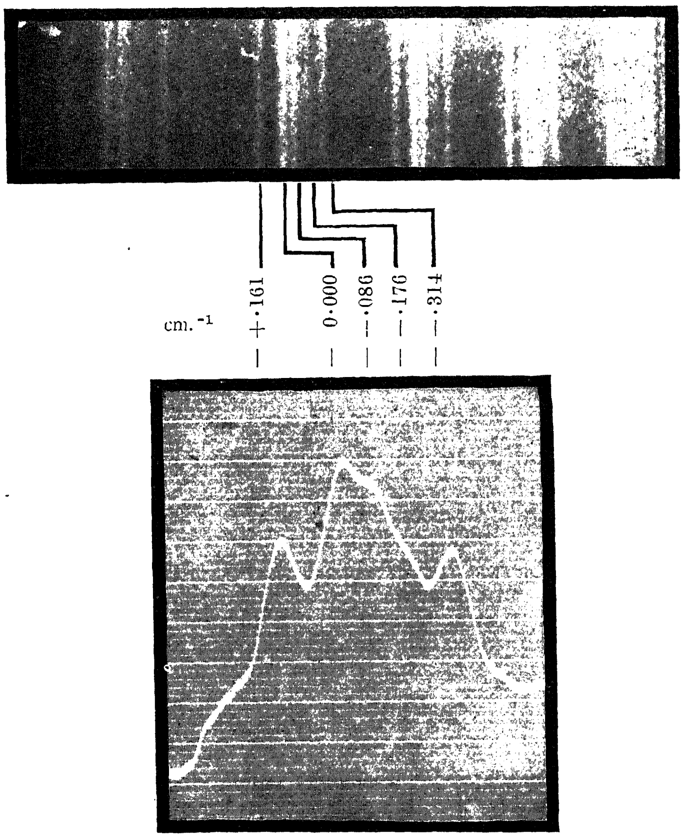

Fig. 4.

Structure Pattern of Pt I λ 3408·13 Å with Microphotogram.[2,3]

photographed on hypersensitive panchromatic plates.

The advantage of the experimental arrangement used is that only the lines cor-

responding to transitions to the ground-level or to the levels close to it are excited without introducing complications arising from self-reversal. From the standpoint of hyperfine structure analysis these are generally the significant lines. For platinum and iridium the transitions giving rise to the lines excited are shown in the diagram above (Fig. 3).

Platinum.—The photograph of the structure pattern of the line Pt I 3408·13 Å ($a\,^3F_4 - z^5D°_4$) has five components. In interpreting this pattern, the structures of other lines of platinum have been taken into account.[2] The result of the examination is that the extreme components on either side are due to the odd isotope of mass number 195 with a nuclear spin of ½ and the three inner components are due to the even isotopes of mass numbers 196, 194 and 192. The relative abundance as deduced from measurements on a microphotogram (Fig. 4) is as follows[3] :—

Mass number ..	196	195	194	192
Relative abundance	16	13	10	2

Dempster has recently published* the isotopic constitution of platinum obtained by using a spark discharge between platinum electrodes and a new type of mass-spectrograph. He finds five isotopes; according to him the isotopes 194, 195 and 196 are nearly equal in abundance, isotope 198 is distinctly less in abundance and isotope 192 occurs in very small amounts. One would infer from this that the component ascribed to 192 may be due to the isotope 198 recognised by Dempster. This, however, would give a negative isotope shift instead of a positive one. The centre of gravity of the lines due to an odd isotope lies usually nearer the line due to the lighter even isotope. This rule would be violated if the faint component in the pattern of 3408 Å is attributed to isotope 198. The isotopes 194 and 196 are however markedly unequal in abundance and cannot be said to be nearly equal as would appear from the communication of Dempster to *Nature*.

Iridium[4].—The structure pattern of the line Ir I 3513·67 Å ($5d^8\,6s\,^4F_{4\frac{1}{2}} - 5d^8\,6p\,^4G°_{5\frac{1}{2}}$) is shown in the photogram (Fig. 5). The relative intensities and number of the hyperfine components in the patterns of the lines

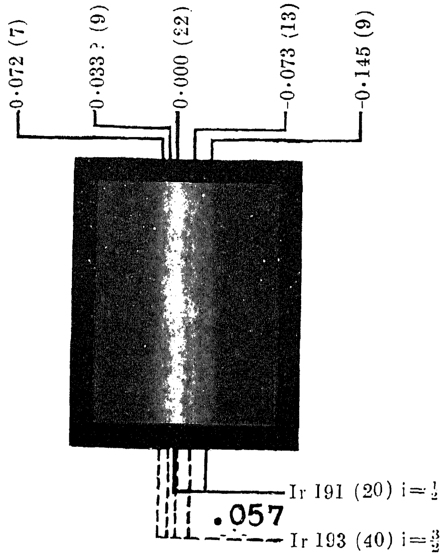

Fig. 5.
Structure pattern of Ir I λ 3513·67Å.[4]

examined and the fact that iridium is an element of odd atomic number with its atomic weight in the neighbourhood of 193 leads to the unique interpretation that iridium consists of two isotopes 191 and 193 with a relative abundance of nearly 1 : 2. The nuclear spin of the isotope 191 is ½ and of 193, 3/2. Isotope 193 gives rise to the four dotted components *a*, *b*, *c* and *d* shown in the figure and isotope 191 gives rise to the two " full " lines A and B in the case of λ 3513·67 Å (Fig. 6).

Palladium.—Using the apparatus above described, Sibaiya who has collaborated with the author in this work has examined the hyperfine structure of the arc lines of palladium and gold.[5] Analysis of fourteen arc lines of palladium belonging to the transitions $5s\,^{1,3}D - 5p\,^{1,3}(P, D, F)$ has revealed an absence of structure in the lines leading to the inference that none of the levels concerned shows any even isotope displacement. An examination of known isotopes in the neighbourhood of palladium indicates that an odd isotope of mass 105 should exist in palladium. The hyperfine structure data show that the percentage abundance of this isotope exceeds 10%, and that its nuclear magnetic moment is small. The nuclear spin of Pd 105 cannot be fixed with certainty but the value ½ is probable. The absence of even isotope displacement in

[5] Sibaiya, "Hyperfine Structure in Selenium, Palladium and Gold," *Proc. Ind. Acad. Sci.*, 1935, **2**, 313.

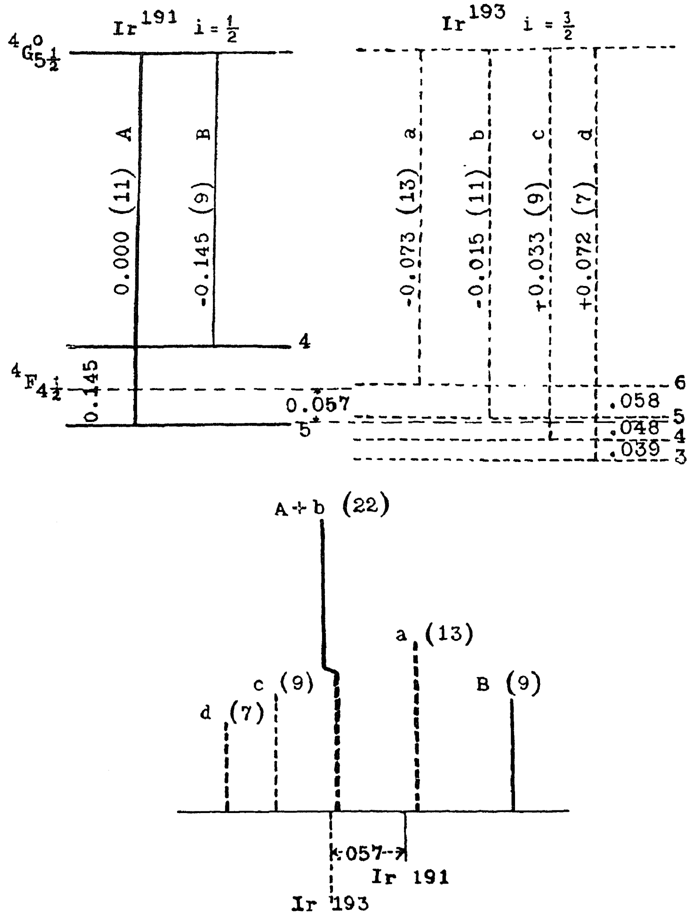

Fig. 6.

Ir I λ3513.67 Å ($5d^8 6s\ ^4F_{4\frac{1}{2}} - 5d^8 6p\ ^4G^o_{5\frac{1}{2}}$)

palladium has rendered the determination of its isotopic constitution from a study of the hyperfine structure of its arc lines alone not possible. Recently Dempster has reported† six isotopes for palladium with masses 102, 104, 105, 106, 108 and 110. The four middle isotopes are nearly equal in abundance, while Pd 110 is markedly less abundant and Pd 102 is the least abundant in the group.

Gold.—Arc lines of gold involving the level $5d^9\ 6s^2\ ^2D_{5/2}$, which shows large isotope displacements in the isoelectronic spectrum of Hg II, have been analysed. The results show definitely that gold consists of a single isotope of mass 197 with a nuclear spin of $\frac{3}{2}$ and a nuclear magnetic moment of 0·20. The accepted chemical atomic weight of gold suggests however that gold must have another isotope of mass 199; known facts regarding the occurrence of odd isobares, along with the hyperfine structure data, point to the conclusion that Au 199 is entirely absent. Thus it follows that the chemical atomic weight of gold is too high. The more recent mass-spectrographic results of Dempster corroborate the above conclusions. The experimental value of the nuclear g(I) factor, *viz.*, 0·136, is in good agreement with Landé's theoretical value, 0·133.

In conclusion one may remark that platinum, iridium and gold are perhaps the only elements, whose isotopic constitution has been first revealed by a study of the hyperfine structure of the spectral lines.

Tree Ring Dating of Archæological Finds.

By R. Maclagan Gorrie, D.Sc.
(*Indian Forest Service.*)

THE reactions of the annual rings of wood laid down in the ordinary process of a tree's growth have been known for long to show some definite relationship to the climatic conditions under which the tree has grown. The credit for employing timber rings as a means for the accurate dating of prehistoric monuments goes to an American worker, Dr. A. E. Douglass, of the University of Arizona. By profession an astronomer, he first became interested in tree ring data in an effort to locate sun-spot cycles through the drought periods associated with them. Beginning as a casual enquiry into climatic influences, it developed into an appreciation of the valuable and accurate record which tree rings can add to local climatic history, and was then applied to the accurate dating of many of the pre-historic Pueblo ruins and cliff dwellings of the American South-West.

These relics of a past civilisation had long intrigued archæologists, but there was much doubt and argument over their actual age until tree ring dating changed speculation into hard fact. Some of these cliff dwellings were thought to be as old as 1000 B.C., but the earliest so far excavated has now been definitely dated 919 A.D., showing an error of almost 2000 years on the previous calculations based on other archæological matter. So accurate is this method of dating that the years of construction and occupation of individual houses have been worked out from the charred remains of roof timber and from unconsumed charcoal fuel. The Pueblo building activities are shown to have fallen off with each drought period until a great drought in the years 1276 to 1299, which was so severe that it completely destroyed most of their agricultural system of small inundation canals.

During a recent visit to America I had the privilege of studying Dr. Douglass' methods at Tucson, Arizona, and was much impressed by this example of scrupulous exactness in detailed research; so, a short account of the technique of his tree ring dating should be of some interest to scientific workers in various fields. Starting with the identification of individual year-rings in different trees from the same region, a calendar was gradually built up dating from living trees as far backwards into the past as contemporary trees or recently felled stumps would reach. It was found that the very arid and severe climatic conditions of the South-West were more or less common throughout eastern Arizona and western New Mexico, thus including the whole of a large zone of early Indian activity in the Colorado and Little Colorado basins, and extending further east into the Rio Grande basin. Throughout this vast area the main periods of drought have been a general experience, so that a characteristic pattern of the rings in any tree living in such a period becomes recognisable as a "signature".

Individual trees of course show minor inconsistencies, and in a completely canopied forest a sudden access of light to a crown by the death or removal of its neighbour trees will probably produce a wider ring than could be credited to any small increase in moisture. Actually most of the western yellow pine (*Pinus ponderosa*) and Douglas fir (*Pseudotsuga taxifolia*) which have yielded the best data have grown in a very open forest type, for the country is so arid that it can best be described as an open dry savannah of scattered pine and juniper trees standing in open grass-lands, not unlike the dry *rakh* of the Punjab and Central India except that the tree species are mostly conifers instead of Leguminosæ. Just how far such data from moister and close-canopied forest types would be serviceable is doubtful, for Dr. Douglass' attempts to extend his tree ring chronology into the moister Californian forest types, with their temptingly long-lived species such as *Sequoia gigantea* and *sempervirens*, have not been so successful. The easier the growth conditions for the individual tree, the less it reacts in its growth to the hardship of individual years of drought, *i.e.*, it is "complacent" while the tree living in more trying conditions is more "sensitive" in its registration of drought years.

From present-day specimens the data can be carried back into the past by searching for timber from old dwellings, comparing their records, and linking them by "cross-dating" them to the ring patterns of known age. Gradually a series can be built up,

the outer rings of such old logs being matched with the oldest parts of modern trees. Small specimens can be cut from living trees with a simple boring instrument such as the Pressler's borer, which extracts a thin sliver of wood 1/8″ thick and showing the rings upto 3″ from the living bark. This, however, is not strong enough to sample the indurated wood of very old logs, and Dr. Douglass has used as a borer a steel tube 1″ in diameter with saw teeth at the end, which extracts an 8″ sample. Where a butt or stump is exposed, a triangular sample of the whole series of growth rings can be taken by making two slanting saw cuts across the face through the heart of the log, thus nicking out a piece on which every ring is exposed in cross-section.

In the actual analysis of rings, complications commonly met with are first, that small rings may be missed altogether, and second, that the double rings frequently caused by two wet seasons in one year may be mistaken for two annual rings. These can only be recognised after considerable practice, double or false rings having no sharp edge of ripened and flattened cell-walls such as characterise true autumn wood. This feature of false rings is a common source of inaccuracy in forest statistical work when doing ring counts to calculate the period of time required to grow trees of a given diameter, and even after considerable experience in wood anatomy one is liable to be misled. The only way to ensure accuracy, therefore, is to build up a chronological table of ring patterns from so many samples that the elusive microscopic ones and the locally common false ones are cancelled out over as wide a district as possible.

It was many years before a complete chronological table for Arizona could be built up, and in the interval the gradually accumulated data for the prehistoric timber from various excavated sites and derelict dwellings were built up into a "floating" table of relative dates. The position of this floating table in history could only be defined when sufficient links had been found to fill the gap beyond the oldest modern pine trees near Flagstaff, Arizona, which reached back to 1707. Many of these links were found in the roof beams from Hopi Indian dwellings, some of which are still in use with timber which has been felled several centuries ago. The last link connecting the floating table with this well-verified historical scale which stretched back to 1300 was finally provided by a buried and charred beam which was so fragile that it had to be well wrapped with twine before it could be lifted.

The coincidences between wood samples are more easily traced from small rings than from large ones, and the rings on each sample are charted on graph paper, giving an exaggerated upright line value for each small ring inversely proportional to its size (Fig. 1). A non-technical account of the work so far accomplished by Dr. Douglass and his helpers is given in "National Geographic Society Contributed Technical Papers; Pueblo Bonito Series, No. 1," Washington, 1935.

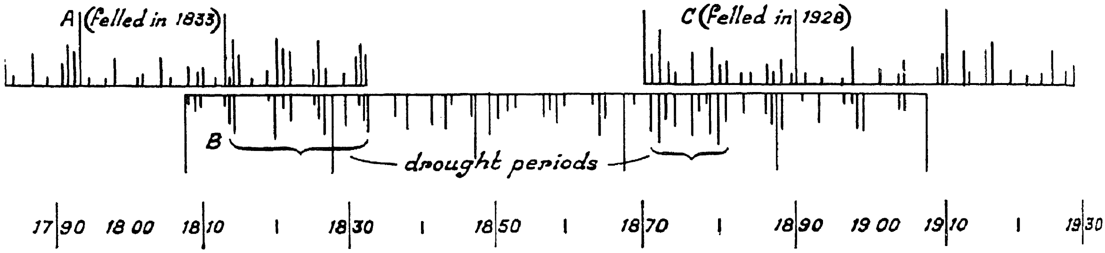

Fig. 1.
"Skeleton plots" showing small ring features of each timber specimen, and the process of matching characteristic groups of rings to build up a chronological table.

From a social aspect it is interesting to find that although the eclipse of the old Pueblo culture was in part due to a series of severe droughts, it was largely self-imposed through the wide-spread destruction of their upland pine forests by felling, burning, and heavy grazing. This was inevitably followed by excessive floods and droughts which rendered impossible their previous agricultural system of flood-water farming on the irrigable bottom lands along the outflows from these pine forest catchment areas. This corresponds roughly with what is happening to-day in many of the drier parts of the United States and the drier tropics of India and Africa, where the

natural vegetation has been destroyed by gross over-grazing and injudicious ploughing of natural grass-lands. In such places the contemporary local tree growth records will be found as a lengthening series of microscopic rings, just as in the period when the Pueblo culture was rapidly dying out. Dry spells may be inevitable, but their effects could largely be mitigated if we could, through a better knowledge of climatic cycles, foretell their arrival, and prepare for them through a more conservative use of the local resources of grass and timber. It is to be hoped, therefore, that some research may be taken up to show how far such data can be used to solve Indian problems in human and climatic history.

On the Structure and Function of the Ascidian Test.

By Dr. S. M. Das, D.Sc.,
Department of Zoology, Lucknow University.

THE present communication is intended primarily to supplement our knowledge of test of Tunicata, and secondarily to demonstrate that the test should not, as in the past, be regarded merely as an exoskeleton but should be considered as a medium for the communication of the animal with the outer world—comparable to the skin of the higher animals. The author's investigations were carried out on the test of the ascidian *Herdmania*, this animal being of a fairly large size and well represented in the coastal waters of South India.

The test of ascidians has been described by many authors in the past. Of recent years, Morgan[1] (1891) described the origin of the test cells; Herdman[2] (1899) gave a detailed account of the test in *Ascidia*; while Miss Herdman[3] (1924) worked out the histology of the test of *Botryllus*. None of these investigators, however, makes any mention of the presence of nerve-cells or of any nervous mechanism in the test. The author[4] has, however, demonstrated the presence of nerve-cells, nerve-fibres and receptor cells in the test of *Herdmania*.

The test, which except for the branchial and atrial apertures is the only part of the animal visible externally, surrounds the body of the ascidian and is about 4 to 6 mms. thick. At the postero-ventral end of the animal, however, the test is 2 to 3 cms. thick and constitutes a "foot" by which the animal remains attached to the sea-bottom. It is soft and leathery, more or less translucent and on sectioning cuts like soft cartilage. As in other ascidians it is composed of tunicine[5]—a close ally of cellulose. The general substance of the test consists of a clear matrix in which are present a large number of cells, interlacing fibrils, minute spicules and branching and anastomosing vascular tubes.

Test Vessels.—There are two main blood vessels, the *sub-endostylar test vessel* and the *sub-intestinal test vessel*, which enter the test and ramify into innumerable fine branches in its substance sending a few large branches into the "foot". These test vessels branch, anastomose and send fine branches towards the outer surface of the test where they end in ovoid or rounded terminal knobs or ampullæ (Fig. 1). The ampullæ appear red in colour due to the presence of red pigment in the ectodermal cells which cover them. These ampullæ appear very close to the outer surface of the test and thus bring blood into close contact with the oxygenated water in which the animal lives. They, therefore, form an apparatus for accessory respiration, which may be compared with the cutaneous respiration in other animals. The only other description of a respiratory organ besides the branchial sac (pharynx), in Tunicata, is that of Herdman[6] (1885).

The Spicules.—The spicules found in the test are of two types: the *microscleres*, which are very small in size, and the *megascleres*, which are much larger. They are all calcareous and have a definite shape

(Fig. 2). The microscleres are found in large numbers scattered throughout the test substance. Each spicule consists of a knob-like head and an elongated body bearing spines arranged in rings. Two kinds of megascleres have been found: the *spindle-shaped* and the *pipette-shaped* spicules. The spindle-shaped ones are enclosed in a connective tissue sheath and are present mostly in the postero-ventral half of the test, where they form a covering round the larger vessels traversing the test. As in the case of microscleres, each spicule has a large number of rings of spines. The pipette-shaped spicules are larger than the spindle-shaped variety and differ from them in having a swelling in the middle. They are, however, never found in the test, being confined mainly to the mantle. Herdman[7] (1885) gave a description of calcareous spicules in Tunicata and later[8] (1891) founded the genus *Rhabdocynthia* (*Herdmania*) on the presence of spicules. But he seems to have missed the pipette-shaped spicules altogether and has also made no mention of the exact structure, arrangement and distribution of the spicules.

Test Cells.—The *cells* of the test are of many different kinds. Five different kinds of cells can be discerned in *Herdmania* (Fig. 3) besides the nerve-cells and receptor

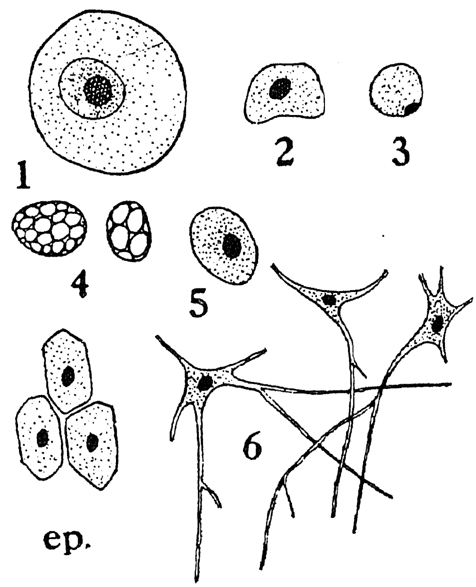

Fig. 3.

Cells found in the test.—1. Large eosinophilous cell; 2. Amœboid cell; 3. Small eosinophilous cell; 4. Vacuolated cells; 5. Granulated cell; 6. Nerve cell; *ep.*, epithelial cells from an ampulla.

cells described later. The largest of these are (1) the few *large eosinophilous cells*,

---

[8] Herdman, W. A., "A revised classification of the Tunicata", *Journ. Linn. Soc. Zool.*, **23**, 575.

usually spherical in shape and staining a bright red with eosin. The cytoplasm consists of a thin homogeneous mass of fine granules and the nucleus is a large vesicular structure in the centre of the cell. Next to these in size are (2) the *amœboid cells*, which are few and far between. The most abundantly represented cells, however, are (3) the *small eosinophilous cells* each with an excentric nucleus. They are scattered throughout the substance of the test but are more abundant in the inner half of the test than the outer. Further, there are (4) the *spherical vacuolated cells*, each of which may consist of three to four chambers or may contain a large number of small vacuoles. A nucleus cannot be seen in these cells. Lastly, near the outer surface of the test are (5) a few *granular cells*[9] with large nuclei, around which the nerve-fibrils of the test get specially concentrated. The large bladder-cells present in the test of *Ascidia*[10] and some other ascidians are not represented in *Herdmania*, unless the small spherical vacuolated cells are to be regarded as remnants of them.

Nerve-cells and Nerve-fibres.—When an ascidian is kept in a tank containing fresh sea-water and the stimulus of contact applied to various parts of the external surface (test), the animal is seen to respond to the stimulus in a definite manner. On touching the siphons with a hard body they are seen to contract, usually closing the branchial and atrial apertures in this way. The rest of the test, however, is not so sensitive as the siphons. Nevertheless, a sharp pin-prick on the test of the body proper also causes an immediate contraction of the part stimulated followed by a general contraction of the siphons and the body proper. The idea naturally followed that nervous tissue should be present in the test to enable the animal to feel the prick. Quite thin sections of the test, properly stained, revealed on examination a large number of cells in the test substance which resemble very much the nerve-cells of the higher animals.

Each nerve-cell (Fig. 3, 6) is pyriform, triangular or polygonal in shape, contains a large nucleus and gives out two to six dendrites which get very much elongated, join similar processes from other nerve-cells and form a network of nerve-fibrils in the matrix of the test. The nerve-fibrils thus serve to connect the various nerve-cells with one another. The nerve-cells are more numerous in the test of the siphons than in that of the body proper and more so in the outer part of the test than in the inner. This is as it should be, if we take into account the greater sensitivity of the siphons and the fact that stimuli always affect the outer part of the test first.

Receptor Cells.—The external surface of the test of *Herdmania* can be divided into (1) the vascular areas, which have numerous vascular ampullæ, and (2) the non-vascular areas which have no ampullæ. Sections through the vascular areas of the test, when properly stained, revealed the presence of fine nerve-fibrils leading distally into the polygonal ectodermal cells surrounding an ampulla, usually a single nerve-fibre terminating in each cell (Fig. 4). Proximally, these nerve-fibres run on for some distance towards the base of the ampulla and then join to form a thicker nerve-fibril that runs on in the matrix of the test and is continued into the processes arising from the nerve-cells. It is quite clear, therefore, that in the vascular areas of the test, the epithelial cells surrounding the ampullæ form centres for the reception of stimuli. The nerve-fibrils communicate

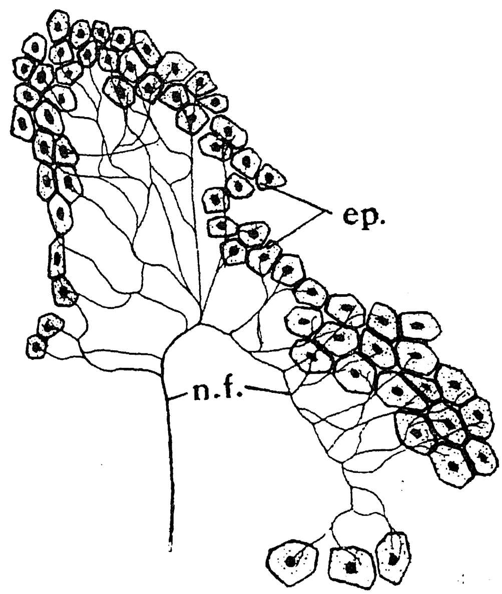

Fig. 4.

Nerve-fibres of an ampulla.—*ep.*, epithelial cells; *n.f.*, nerve-fibres.

[9] See account of receptor cells.

[10] Herdman, W. A., "L. M. B. C. Memoirs", I, *Ascidia.*

the stimuli to the nerve-cells. Experiments, however, showed that not only were the vascular areas of the test sensitive but that a pin-prick on the non-vascular areas of the test also produced similar effects though less marked in degree. Sections of the test through the non-vascular areas, revealed the presence of some ovoid cells, around which the nerve-fibrils of the test get specially concentrated. The presence of these cells in the non-vascular areas of the test, and their absence in the vascular areas, give additional proof that they have the same function here as that of the epithelial cells in the vascular areas.

Stimuli are, therefore, received by these receptor cells in the test and conducted by the nerve-fibrils which transmit them to the nerve-cells. Further, some nerve-fibrils from the nerve-cells pass into the mantle and finally join the nerves leading into the nerve-ganglion or brain. The instantaneous reaction to stimuli clearly shows that the nervous mechanism of the ascidian—though the nerve ganglion is said to be the degenerate representative of the larval brain and nerve-cord—is really very well developed.

Growth and Organisation of the Test.—The test in a living ascidian is continually worn at the surface. Growth takes place by the formation of tunicine by the ectodermal cells lining the inner surface of the test and also by the mesodermal cells which migrate into the test through the walls of the test vessels and the vascular ampullæ.[11] The new test always gets organised by the immigration of the various kinds of cells into it. The test as a whole, therefore, not only serves for the protection and attachment of the animal (facts mentioned in most text-books of Zoology) but also acts as a respiratory and a receptor organ.

Mention must be made here of the fact that this is the first time in the history of our knowledge of the Tunicata that a definite nervous mechanism has been demonstrated in the test or outer covering of these animals. The author wishes to express his thanks to Dr. Sundara Raj of the Madras Fisheries Department for placing the resources of the Tuticorin Fisheries Station at his disposal for the collection of material. Acknowledgments are also due to Prof. N. J. Berrill of Montreal and Prof. E. S. Goodrich of Oxford for their kind suggestions. To Prof. K. N. Bahl of Lucknow he is very much indebted for taking keen interest in the progress of the work.

Theoretical Biology.

To promote the study and work in the field of Theoretical Biology, a foundation for Theoretical Biology of animal and man, has been founded at the University of Leiden. In memory of the late Professor of Zoology, Van der Hoevèn (1801–1888), the author of the "Philosophia Zoologica," it is called "Professor Dr. Jean van der Hoeven Stichting von theoretische biologie van dier en mensch". The chief objects of the foundation are (1) to arrange for lectures at the University of Leiden, (2) to bring to Leiden, biologists who are interested in theoretical biology into contact with their colleagues in Holland and abroad, to bring about a contact for scientific purposes and organisations between theoretical biologists all over the world, for instance, by arranging international symposia on theoretical biology, (3) to publish articles on theoretical biology, and (4) to found a library on this subject. Directors of the foundation are Dr. C. J. van der Klaauw, Professor of General Zoology and Dr. T. A. T. Barges, Professor of Medical Anatomy, both at Leiden, and Dr. Adolf Meyer, Professor of Theoretical Biology at Hamburg.

Obituary.

Dr. Paul Brühl (1855—1935).

PROF. PAUL JOHANNES BRÜHL was born in Saxony on the 25th February 1855 and was the only surviving son of Michæl Brühl. He finished his early education in German schools and colleges and joined the botanical touring party obtaining the travelling scholarship, as was customary during those days. He walked all the way through Central Europe, Asia Minor and Armenia after halting for a short period at Constantinople where he worked as a teacher for some time. During his tour he made valuable botanical collections. He reached India in 1881 and joined the Rajshahi College in 1882 as a teacher of Natural Sciences. In 1883 he married Annie Betts Fox. His botanical interest was known at this time and the reputed Botanist Sir George King, the then Superintendent, Royal Botanic Garden, Calcutta, got him transferred to the Bengal Engineering College in 1887. Here Prof. Brühl taught various subjects such as Chemistry, Physics, Geology including Mineralogy, Heat Engines and Agriculture. His vast knowledge in many subjects and more than fourteen languages and art of teaching and laboratory methods were of a high standard which soon gained explicity all over this country. His popularity and sympathy towards his students and his keen interest in their welfare made Prof. Brühl's name a household word in many a Bengali house. His research work in Botany during his off time after the teaching work at the Engineering College found expression in such voluminous publications as *A Century of New and Rare Indian Plants* in collaboration with Sir George King. This work was published in the *Annals of the Royal Botanic Garden, Calcutta*, Vol. V, part II with 102–200 plates, most of which are Brühl's own sketches. His papers on "Plant Immigrants" is an important contribution towards the distribution of foreign plants in India. He officiated as the Principal of the Engineering College for some time. He retired from the Engineering College in 1912 and in recognition of his valuable and faithful service for forty years in the Government Educational Department, the title of Indian Service Order was conferred upon him by the Government of Bengal. After his retirement from the Government service his interest for research work did not abate. In 1912 from October to March, he worked in Chemical Geology in the Indian Institute of Science, Bangalore. He was for some time teacher in Geology and Mineralogy at the Presidency College, Calcutta, and officiating Patent Secretary to the Government of India. At the request of the late Sir Ashutosh Mukerjee, he accepted the post of the Registrar, Calcutta University, in 1913, and worked as a Registrar, Controller of Examinations and Secretary of the Arts and Science Department of the post-graduate classes which was just developing at this time. He had also to offer his valuable suggestions in building up the Post-Graduate Laboratories and was subsequently entrusted to build up the Biological Laboratory of the Calcutta University and was appointed the University Professor of Botany. His scientific investigation was recognised by the University in offering him Doctor of Sciences as *Honoris Causa*. As a University Professor he is one of the pioneers in the investigations of the Lower Cryptogams and in forming the present Indian Botanical Society of India. Here, as a teacher of the post-graduate classes in Botany again, he was able to contribute a large number of papers in Botany—his much beloved subject—in collaboration with his students. As president of a Committee appointed by the Government of Bengal, his research work, financed by the Government of Bengal, on the eradication of Water Hyacinth from 1925 onwards resulted in the publication of many papers which suggested various avenues of investigation on this vital question.

Among his many publications his latest contribution entitled "A Census of Indian Mosses" published in the *Records of the Botanical Survey of India*, Vol. VIII, 1930, and his book on "Sikkim Orchids" are of the greatest value to the botanical investigation in India.

He has left one son and three daughters and many successful students, friends, colleagues and admirers to mourn his loss.

K. BISWAS.

Letters to the Editor.

The Nature of the Transition from Troposphere to Stratosphere and Upper Air Temperatures over India in the Winter and Hot Seasons.

USUALLY in the tropics, the decrease of temperature with height which characterises the lower atmosphere, ceases suddenly at a height of 16–18 gkm. and a rise of temperature with height commences. In the winter and early hot season in N. India, below the above-mentioned inversion, there is often found another inversion or isothermal layer or layer of very small positive lapse-rate which may be more than 2 or 3 km. thick. Examples of such layers are shown in Fig. 1. The lower limit of this region may sometimes be as low as 10 gkm. in N. India. Dr. K. R. Ramanathan and Mr. K. P. Ramakrishnan in their paper on "Sounding Balloon Ascents at Poona and Hyderabad" explained this type of structure as being due to a meridional movement of air near the tropopause, the upper transition corresponding to the usual tropopause of tropical latitudes and the lower one to that of temperate latitudes. With a view to analyse the conditions of

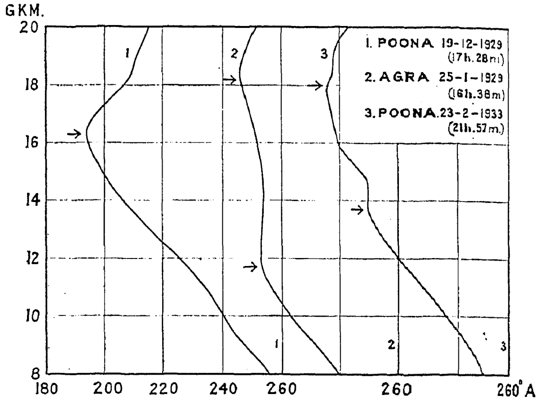

Fig. 1.

upper air temperature associated with this composite type of tropopause, the available sounding balloon data at Agra during the

period November-March 1925–31 were arranged into three groups: (1) when a lower transition was present between 10 and 12 gkm., (2) when it was present between 12 and 14 gkm., and (3) when there was no evidence of such a transition below 14 gkm. Fig. 2 shows the average temperatures at different levels corresponding to each of

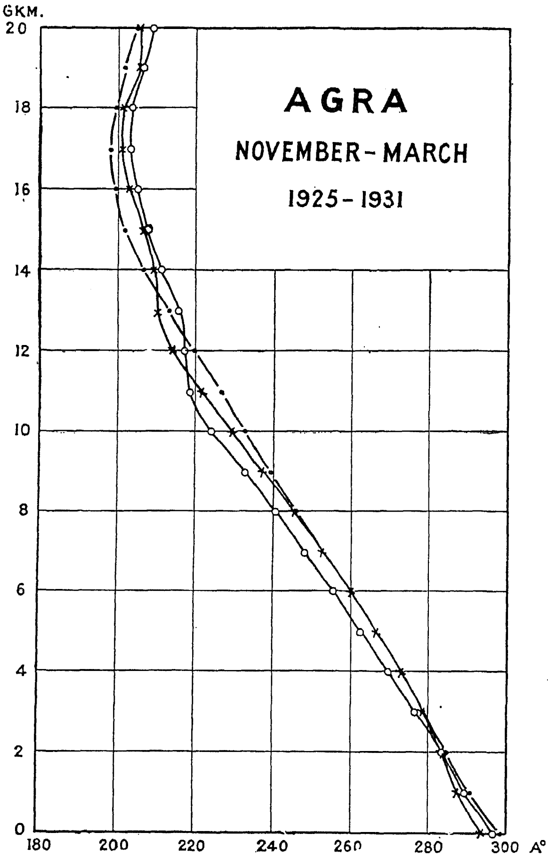

Fig. 2.

Mean Height Temperature Curves on days when a large decrease of lapse rate occurred.

(1) Between 10 & 12 gkm. O—O
(2) ,, 12 & 14 gkm. ×—×
(3) Above 14 gkm. ●—●

these three groups. It is clear from the figure that on the average, the presence of a lower transition is associated with abnormally cold air between 4 and 12 gkm. and abnormally warm air above 13 gkm. The occurrence of the tropical type of tropopause in this season goes on the average with higher temperatures upto 12 gkm. and lower temperatures above.

The frequency table (Table I) given above shows that while the presence of a lower transition is generally associated with abnormally low temperatures for 3–6 gkm. below that level, the converse proposition that extra low temperatures at say 8 to 12 gkm. are generally accompanied by a lower transition immediately above, is less certain.

As the upper inversion at 16–18 gkm. is present in more or less pronounced form on all occasions, we have to consider that it is due to some permanent cause—probably the presence of ozone. When meridional advection brings up air of lower latitudes to north India at these levels, the upper inversion may be expected to be more pronounced and conversely, when air from higher latitudes is brought over, the inversion will be less pronounced. Over Poona, the composite type of tropopause is less common, and when it occurs is less well-marked than

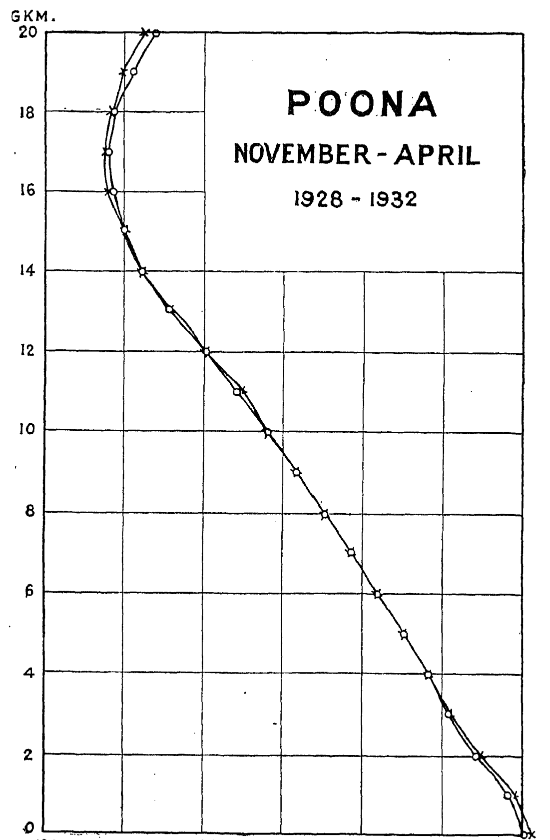

Fig. 3.

Mean Height Temperature Curves on days when a sudden decrease of lapse rate occurred.

(1) Between 13 & 15 gkm. O—O
(2) Above 15 gkm. ×—×

over Agra. It was therefore considered sufficient to analyse the Poona data into two groups: (1) when there was evidence of a lower transition between 13 and 15 gkm. and (2) when there was only one transition above 15 gkm.

Fig. 3 gives the average temperatures at different levels over Poona corresponding to each of these two groups. The difference between the two sets of averages is insignificant. Meridional advection can be expected to show the characteristic double transition best in those latitudes where the rate of change of height of tropopause with latitude is large. Agra lies in such a region in winter while Poona does not.

I am thankful to Dr. K. R. Ramanathan for suggesting this analysis.

Poona, M. W. CHIPLONKAR.
September 27, 1935.

Further Observations on the Diamagnetism of the Trivalent Bismuth Ion.

IN our note on the subject,[1] the value (43·80) for the diamagnetism of the trivalent bismuth ion was obtained by modifying the original Slater formula by assigning for electrons in the lower groups instead of shells and the *d* and *f* groups a value 0·85 instead of the usual 1. We have now calculated the value for Bi^{+3} by the orthodox Slater formula and its modification proposed by Angus and obtain the following results:—

		Experimental	Slater	Angus
$-x\times10^6$	Bi^{+3}	41·24	42·23	42·09

The agreement is as good as can be expected particularly on the Angus formula. More so when one realises that the Slater method is strictly valid for ions of the closed configuration type. Kido has brought out an interesting empirical relationship which seems to hold for a number of ions according to which the difference in the susceptibilities of ions due to two electrons is of the following order:—

	$-\Delta x\times10^6$
$P^{+3}-P^{+5}$	= 9·4
$As^{+3}-As^{+5}$	= 8·2
$S^{+4}-S^{+6}$	=10·4
$Se^{+4}-Se^{+6}$	= 9·5
$Cl^{+5}-Cl^{+7}$	=11·1
$I^{+5}-I^{+7}$	=12·5

The value for Bi^{+5} for which the Slater and Angus formulæ should strictly apply, has been calculated to be 29·22. The difference between Bi^{+5} and Bi^{+3} calculated on the Angus formula is 42·09—29·22=12·87, which is of the same order as suggested by Kido and is of particular significance.

It may be recalled here that out of the many compounds of bismuth mentioned in our last note, the susceptibility values of four are described in the *International Critical Tables* (Bi_2O_3, $BiCl_3$, $BiBr_3$, BiI_3). Three of these are in excellent accord with our values and only one has been shown to have a lower value.

Full results are being communicated to the *Journal of the Indian Chemical Society*.

Some Aspects of the Mechanism of Non-Symbiotic Fixation of Atmospheric Nitrogen.

PREVIOUS studies on the economy of carbon during fixation of atmospheric nitrogen by Azotobacter, particularly by Stoklasa[1] and by Ranganathan and Norris[2] would suggest that the nitrogen fixers derive their organic nutrition chiefly from carbohydrates, though small quantities may be fixed in presence of other organic substances as well.

Our studies with the mixed flora of the soil showed that glucose which was provided as the organic nutrient was completely decomposed in the course of the first four days, being mostly converted into gases. Of the residual organic matter, 44·1 per cent. was accounted by micro-organisms (living as well as dead), 34·0 per cent. by organic acids (chiefly lactic, acetic, propionic and butyric) and the rest in some (yet unidentified) water soluble form. During this period only about a third of the usual quantity of nitrogen was fixed, and of this, the major part was present in water soluble form. In the course of the next four days a large part of the organic acids was lost, accompanied by corresponding increase in mucilage. There was also rapid fixation of atmospheric nitrogen, the C-N ratio of the organisms changing from 62·1 to 20·6. Between the 8th and the 12th days, there was very little change in the other constituents, but there was further fixation of nitrogen. After the 12th day, there was

slight loss of organic carbon, but there was no appreciable fixation of nitrogen.

TABLE I.
Distribution of Organic Carbon.

Time in days	Carbon in mg. (as present in 50 c.c. of medium)				
	Total organic carbon	Sugar	Organic acids (so far identified)	Microbial tissue	Unidentified
0	173·7	170·4	Nil	Nil	Nil
2	111·7	83·6	13·2	13·6	Nil
4	55·0	Nil	19·8	24·2	7·7
8	53·4	Nil	5·8	39·8	4·5
12	55·5(?)	Nil	4·8	39·9	7·5(?)
16	50·5	Nil	..	39·4	..

Carbonate carbon (including dissolved CO_2) was estimated at each stage, but has not been included. The soil used for inoculation contained 3.3 mg. of carbon.

TABLE II.
Nitrogen Fixed and C-N Ratio.

Time in days	Nitrogen fixed in milligrams in 50 c.c. medium		C/N	
	Total	In bacterial tissue	In the whole medium	In bacterial tissue
0	Nil	Nil	..	..
2	0·78	0·39	143·2	43·9
4	1·26	0·39	43·7	62·1
8	2·42	1·93	22·1	20·6
12	3·07	2·90	18·0	13·8
16	3·15	2·95	16·0	13·4

TABLE III.
Distribution of Organic Acids (so far identified).

Time in days	Organic acids in mg. of carbon (in 50 c.c. medium)					Total acids
	Non-volatile	Volatile				
	Lactic	Acetic	Propionic	Butyric	Total	
2	6·1	2·7	0·6	3·8	7·1	13·2
4	12·8	3·1	0·4	3·5	7·0	19·8
8	Nil	..	..	..	..	5·8
12	Nil	..	..	..	..	4·8

It would be seen from the above that (*a*) the carbohydrate contributes only partly to the fixation; (*b*) organic acids are mostly utilised for the growth of the organisms and fixation of nitrogen; and (*c*) the production of mucilage and nitrogen fixation, though related, are not directly proportional to each other.

That the immediate products of decomposition of sugar are utilised in the fixation is further proved by the following results (Table IV):—

TABLE IV.

Time in days	Nitrogen fixed in mg. (in 50 c.c. of medium)	
	Residue sterilised and freshly inoculated	Unsterilised (control)
4	0·25	2·10
8	1·62	2·62

Further work is in progress to determine (*a*) the manner in which organic acids or their calcium salts assist in fixation, and (*b*) the nature of the water-soluble nitrogen formed in the early stages and its relation to the subsequent fixation. The studies are also being extended to pure strains of nitrogen fixers.

The Occurrence of Azotobacter at High Temperatures.

A GOOD deal of controversy has been going on for some time past, with regard to the action of light in tropical soils on such important soil phenomena as Nitrification, Nitrogen fixation, etc. Since Azotobacter and other Nitrogen-fixing organisms flourish the most between 25°C. and 30°C. and undergo encystment at higher temperatures, it is assumed by some investigators that when soil temperatures are higher than 30°C. in summer, no physiological activity can be expected from the Nitrogen-fixing organisms. It would perhaps be

worth while to test the correctness of the assumption by actual examination of the soils which have attained higher temperatures in summer for the presence of Azotobacter and other Nitrogen-fixing organisms. We have endeavoured to find information on this point by examining a few soil samples taken in June last when typical summer conditions were prevailing.

The following table would show the atmospheric temperature, soil temperatures and moisture contents of the soils:—

Soil Used	Atmospheric Temperature. °C.	Soil Temperature °C.	Moisture Contents %
1. Cultivated soil with low Moisture Content ..	49	44	8·6
2. Cultivated soil with high Moisture Content ..	,,	42	21·1
3. Garden Soil	,,	42·5	19·5
4. Grass Soil	,,	45	0·36

Samples of soils mentioned above were divided into two portions of equal weights, one lot of each soil was heated upto 80° C. for ten minutes so as to kill all the vegetative forms, and the other lots were left unheated.

A small quantity from each of these eight soil samples, *viz.*, four heated ones and other four un-heated ones, were inoculated in the liquid Ashby's mannite medium. After a few days' incubation at room temperature the pellicle was observed in all the unheated soils, while no pellicle could be seen in the heated samples. Dilutions were also made from each flask and each dilution after addition to Ashby's mannite Agar was plated out in sterilized Petri dishes. In a few days' time the Azotobacter colonies appeared along with some other bacteria in the plates of the unheated soils. In the plates of heated soils, however, other types of bacteria appeared while Azotobacter colonies were very few or none at all in number. Pure cultures were made from Azotobacter and other bacterial colonies appearing on the plates and are kept for further work.

It is not possible at this stage to write definitely regarding the species of Azotobacter which have been observed at such high temperatures in all the samples stated above, but the view held by some investigators that photo-fixation of Nitrogen is the only process of Nitrogen-fixation prevailing at temperatures higher than 30° C. can no longer be maintained, because it has been amply proved that Azotobacter cells are present in the vegetative state in the soil at temperatures as high as 45° C.

This is probably an instance of the frequently observed phenomenon of the adaptation of living organisms to their environments.

Pungency in Chillies (*Capsicum annum*) A Mendelian Character.

Chillies (Red pepper) is one of the important agricultural crops of South India and it is grown mainly for the pungent fruit which is an indispensable item in the dietary of Indians. There are ever so many varieties differing in size, shape, colour and pungency of the fruits. While the varieties grown as field crops are all highly pungent, those grown on a smaller scale and used mainly as a vegetable are not so. The pungent varieties are generally small fruited and contain a large amount of seed while the non-pungent ones are big fruited, more fleshy and contain less of seed. Evidently the evolution of the big-fruited varieties has taken place with the loss of pungency. The variety (*Capsicum frutescens*) which still grows wild in several parts of the Presidency has extremely small fruits and is the most pungent of the group.

The inheritance of a large number of characters in chillies has been studied by Deshpande[1] (1933) but we have not come across any reference to the inheritance of pungency. It has therefore been considered that the information given below with regard to this character will be of interest.

We have been growing recently a large number of chilly varieties at the Paddy Breeding Station, Coimbatore and we have also made some crosses amongst them. One of these crosses was between a variety 'Elephants-trunk'—a long big fruit without any pungency and another small-fruited variety but extremely pungent. The F_1 was found to be pungent and a portion of the F_2 has been raised recently. Due to the unfavourable season, several of the plants had

succumbed to wilt and thrips after transplanting, leaving only 25, which matured and bore fruits. The fruits of these plants were examined individually and it was found that 18 bore pungent fruits while 7 were definitely non-pungent. The non-pungent fruits were easily distinguishable from the pungent though there was a good bit of variation in the latter.

The active principle in chillies which accounts for the pungency is an organic compound with a definite constitution and it is possible, its presence or absence may be tested chemically, but so far as our examination recorded here is concerned, we classified the plants by actually tasting the fruits of each plant. Some more of these F_2's have since been grown and in addition to pungency, other characters like size and shape and the amount of seed present and their association with the pungency character are under study. The results will be published separately.

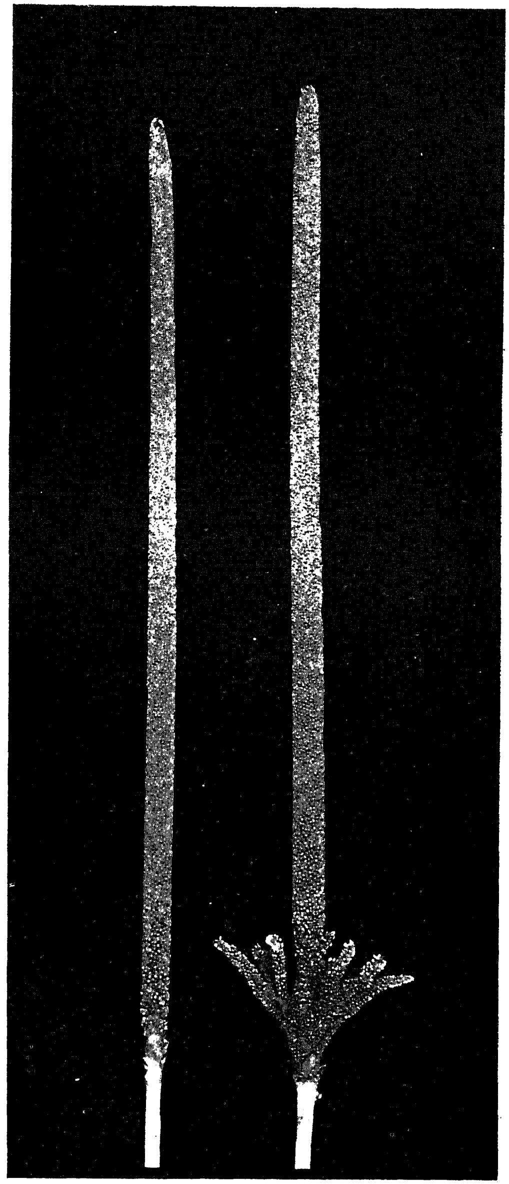
Basal Branching in the Earheads of the Pearl Millet—*Pennisetum typhoides*, Stapf and Hubbard.

THE inflorescence of the Pearl (Spiked) Millet is its characteristic rod-like false spike. Round a central axis are clustered together a number of fascicles having short pedicelled flowers. The hermaphrodite and antheriferous flowers together with the bristle brush constitute the fascicle. This rod-like disposition eminently meets the necessities for the fertilisation of this protogynous, lodiculeless millet with its delicate stigmas.

As recorded by Bews,[1] starting from the spreading type of panicle the main evolutionary trend in grasses has been "towards contraction, condensation, reduction and as a result increased protection". The protogyny and absence of lodicules impose additional needs for this protection in this millet.

Stapf in his description of the Pennisetums of Tropical Africa[2] mentions the occasional occurrence in some specimens from Nigeria of an abnormality in which "many of the lower and intermediate fascicles are replaced by slender spike-like branches up to 8 inches long". Such an abnormality has been experienced at Coimbatore in the case of an odd plant from a variety of the Bellary district.



In the year 1934 in some Sorghum seed imported from Nigeria, there was an odd seed of pearl millet which gave rise to an earhead whose unusual length attracted attention. The basal portion of this earhead was normal and unbranched. The

seeds from this odd plant were sown and a crop raised. In this population a clear segregation between entire and branched bases was noticed. Counts were taken and gave 342 unbranched and 127 branched bases (*vide* illustration). The segregation was sharp.

The branching occurred over an area of two inches at the base. An analysis of this area together with a corresponding two inches of the normal unbranched area gave the following figures:—

	Unbranched area	Branched area
Number of branches ..	..	28
,, fascicles ..	142	1,446
,, grains	437	1,431
,, grains in a 2 gm. weight ..	135	263
Weight of grains (gm.) ..	6·39	10·95
,, chaff (gm.) ..	·96	2·95

The above table clearly reveals the economic disabilities of this branched atavistic condition which has proved a simple recessive to the normal rod-like inflorescence of this millet.

Peucedanum graveolens—A New Host of Powdery Mildews.

DURING the last winter season a local variety of *Peucedanum graveolens* commonly known as soâ—a herbaceous plant used in curries and cultivated for its seeds and leaves—was found to be attacked by powdery mildews. Subsequent observations indicated that the first sign of the disease is found in the appearance of small white specks on the lower filiform leaves. The infected spots enlarge, coalesce and gradually cover the entire assimilating surface. With advance in season, the fungus spreads from leaves to the stem and finally infects the inflorescence. In severe cases the attack is damaging and the seeds fail to mature properly.

The usual organism appears to be similar to what has been described by Uppal and Desai on *Cuminum Cyminum*.[1]

Detailed investigation is, however, in progress and will be reported subsequently.

The Method of Selecting a Representative Sample in Social Research.

By P. V. Sukhatme,
Department of Applied Statistics, University College, London, W.C.1.

IN Social Research, it is often required to estimate the average value of a character of some individuals. Such averages may be calculated whenever possible from the data supplied by the decennial census in India. These data do not, however, always provide the necessary material required for all types of population research and it is, therefore, imperative that fresh inquiries should be undertaken from time to time to collect the material.

It is, however, obvious that an *exhaustive* inquiry cannot be undertaken every time for want of both time and money. Nor is it necessary for the attainment of sufficiently accurate results. It is therefore advisable to base the results on the data supplied by the process of sampling. This process has been termed the 'Representative Method'.

It has been shown by Dr. J. Neyman that the most general aspect of the representative method is that of random stratified sampling of groups.[1] The method consists in dividing the population studied into parts called 'strata' and in sampling randomly from separate strata. The number of sampling elements to be chosen from each stratum may be determined by any one of the following methods :—

(1) The method of proportional sampling suggested by Professor A. L. Bowley.[2]

[1] J. Neyman, *Jour. Roy. Stat. Soc.*, **97**.
[2] A. L. Bowley, *Bull. Int. Stat. Inst.*, **22**.

(2) The method suggested by Dr. J. Neyman.[1]

The first method consists in choosing a number of elements from each stratum proportional to the total number of elements M_i in that stratum. The second consists in choosing a number from each stratum proportional to the product $M_i \sigma_i$ for that stratum. (σ_i^2 denotes the variance of the elements of the ith stratum about the mean of that stratum.) If σ_i^2 has different values in different strata, as is invariably the case, the second method is known to be more accurate than the first.

In general we do not know the values of σ_i. They can, however, always be estimated by means of a preliminary inquiry. It has been shown that if the σ_i's are estimated from sufficiently large samples (each of the order of 20 elements), then Dr. Neyman's method will almost invariably lead to more accurate results. Further it has been found that if the variability of the character sought within the single strata is very different in different strata, the gain in accuracy is of considerable magnitude.

The question of expense connected with the preliminary inquiry has also been considered and it has been found that in most cases Dr. Neyman's method is still advisable and may not prove too expensive.

The details will be found in the forthcoming issue of the Supplement to the *Journal of the Royal Statistical Society*, London.

Occurrence of Lime in Edible Momordica.

By H. L. Chakravarty, M.Sc.,

Herbarium, Royal Botanic Garden, Calcutta.

ABUNDANT deposit of lime in the form of crystals or cystoliths have been observed in the body cells of our common "Uchhya or Corola" (*Momordica charantia* Linn.) and Kakrol (*Momordica cochinchinensis* Spreng). Lime as calcium carbonate occurs in the form of cystoliths in leaves and as calcium oxalate it occurs as crystals mostly in stems and petioles. Portions of the cuticular membrane of the under-surface of the leaves of the two species when seen under the high power of a microscope, groups of globular deposit of calcium carbonate over a cellulose skeleton are visible. Such an aggregation of globular deposit of lime is defined as cystolith. These cystoliths are frequently present in the lower epidermal cells of the leaves and due to deposits of large quantities of calcium carbonate the epidermal cells grow considerably in size. Sometimes they are as large as ten times that of the size of an ordinary epidermal cell. These inflated cells containing cystoliths are gradually pushed into a considerable depth of the mesophyllous tissue and hence in a transverse section they seem to arise from the spongy tissue of the mesophyll.

The presence of the cystoliths of *Momordica charantia* was first observed by an Italian scientist, Dr. Otto Penzig,[1] in 1881. He determined also the nature of the structures of the cystoliths. Zimmermann[2] in his recent monograph on Cucurbitaceæ has described a few European and African Momordica. It appears that no contributions have yet been made towards the anatomical nature of the leaf-cells containing cystoliths of Indian species of Momordica. I have therefore made an attempt towards this direction. A group of cystoliths is the separate deposit of lime in various fantastic aggregations on a central skeleton. Cystoliths generally occur in groups of 2–7. In Fig. 1(A), Plate I, we find a cystolith of triple group as is found in *M. charantia*. In this species cystoliths occur also in groups of 2–4. Sometimes cystoliths are present in as many groups as seven (see Fig. 2(A), Plate I). Such groups of seven are seldom met with. In the process of the growth of cystolith calcium carbonate is strongly impregnated over a cellulose skeleton and when the deposit of calcium carbonate is dissolved in dilute HCl a skeleton of cellulose with concentric stratification makes its appearance. The cystoliths of *M. charantia* are more or less of definite regular oval-shaped structures and are non-branched and monoplanous.

The cystolith of *M. cochinchinensis* appears to have not yet been reported by any previous worker (see Figs. 3, 4). They are mostly irregular in structure, branched and

heteroplanous. In the beginning of the formation of cystoliths in this species the cystoliths do not show much difference from those of *M. charantia* but as they grow up they branch off and ultimately show the characteristic structure as shown in the figure. Here also as in the previous species,

THE STORY OF ISOTOPES.

A HISTORIC account of Isotopes has to begin with Prout's speculative suggestion that all atoms are made up of the particles of some primordial substance. It follows as the result of this hypothesis that the atomic weight of an element must be expressed in whole numbers. It was soon found by chemists that this was not the case and the hypothesis was thus abandoned.

The next landmark in the progress of the idea of Isotopes is to be found in the remarkable statement of Crookes in his Presidential Address, Section B, at Birmingham in 1886, "I conceive, therefore," he said, "that when we say the atomic weight of, for instance, calcium is 40, we really express the fact that, while the majority of calcium atoms have an actual atomic weight of 40, there are not a few which are represented by 39 or 41, a less number by 38 or 42, and so on". These hypothetical components, he called 'meta-elements', but this suggestion of Crookes did not bear any fruit.

The discovery of radio-active phenomena in which the attention of the experimentalist is focussed on the behaviour of individual atoms, led the way to the discovery of elements with identical chemical properties but different atomic weights. The first definite indication of the existence of such elements is to be traced to the discovery by Boltwood in 1906 that ionium and thorium, when mixed together, could by no known chemical process be separated from each other. The radio-active law that when a radio-active element loses an α-particle, it goes back two places in the periodic table and by the loss of a β-particle, it goes forward by one place, may be taken as the first definite formulation of the nature of Isotopes.

Soddy was the first to call two elements having identical chemical properties and difficult of separation when mixed, Isotopes or Isotopic elements, because they occupy the same place in the periodic table. Uranium lead which results from uranium of atomic weight 238 by the loss of eight α-particles has an atomic weight of 206 and thorium lead which results from a loss of six α-particles from a thorium atom has an atomic weight of 208. Soddy put forward the view that the atomic weight of the lead found in uranium minerals must be less and that of the lead found in thorium minerals, more than the atomic weight of ordinary lead, *viz.*, 207·2. In modern nomenclature, it is generally accepted that Isotopes are elementary substances having the same atomic number but different atomic weights. We know now that most of the chemical and physical properties of the isotopes of any element are identical.

Dr. Aston points out that orthodox science was very reluctant at the beginning to accept the view that elements with different atomic weights could have identical chemical properties and he says, "This reluctance of orthodox science to accept the theory was, I think, a perfectly natural and healthy reaction. Criticism very seldom destroys enthusiasm and is usually the best stimulant to further research."

The next advancement in the experimental study of isotopes was the 'parabola' method of positive ray analysis started by Sir J. J. Thomson. These investigations of Sir J. J. Thomson led to the discovery of the two Isotopes of Neon of masses 20 and 22. Aston points out that in these investigations he was associated with Sir J. J. Thomson and as a result of this association, he, after a series of difficult diffusion experiments, was able to show that Neon was not homogeneous by getting two samples of Neon which differed in density by about 0·7 per cent.

It is undoubtedly the mass spectrograph of Aston that placed the existence of Isotopes beyond any possibility of doubt. With the aid of the mass spectrograph, Aston showed that Neon consisted of atoms of mass 20

and 22 in relative abundance of 9 to 1, so that we get the mean atomic weight 20·2. Chlorine, bromine, krypton, xenon and others were analysed and found to be mixtures of Isotopes of different masses. It was established that the "whole number rule" indicated that atomic nuclei were built up of the units, protons and electrons, in appropriate relative numbers to give the atomic number. Dempster at Chicago, with a mass spectrograph of his own design, made Isotopic analysis of magnesium, calcium and zinc.

The two main methods of obtaining the necessary rays for analysis are (1) the ordinary gas discharge which requires that the element under examination should be volatile or should form suitable volatile compounds and (2) the anode ray discharge in which the compound of the element is the anode in a low pressure discharge. In this connection says Aston with truth that "Our knowledge of the mechanism of the discharge in both methods is far from complete, so that working with them is still rather an art than a science. The element of luck has played an important part in cases where the properties of the materials are unfamiliar and unfavourable to the conditions of the discharge."

The four elements, palladium, iridium, platinum and gold, remained without mass spectrograph data. Recently, however, Dempster has analysed platinum and finds five Isotopes. Gold, he says, is single. It is found that no element of odd atomic number has more than two Isotopes. In the case of even elements, *i.e.*, elements with even atomic numbers, the finding is different; tin, for instance, having as many as eleven Isotopes ranging from 112 to 124 in mass numbers. It is also found that up-to the number 210, a stable elementary element atom is known for every number, and often there are 'Isobares,' that is, there are elements with the same atomic weight but different atomic numbers.

Next Aston discusses the technique of the determination of the relative abundance of the Isotopes of an element. The question of 'packing fractions' and the contribution of Bainbridge to the study of Isotopes are discussed. Then in an account of the sensational discovery of the now well-known Deuterium, the heavy Isotope of hydrogen with mass number 2, of the Isotopes of oxygen 17 and 18 and other relevant questions, are taken up for consideration.

"In the field of Isotopes," says Aston at the close of the address, "as in so many fields of physical and chemical research to-day, the objective we now aim at is the next decimal place, an elusive object which always appears to be running away from the observer, like a distant spiral nebula..... In artificial radio-activity and transmutation we see the real beginnings of a great new subject, the nuclear chemistry of the future....... Armed with reliable equations, and thereby with more and more definite knowledge of nuclear construction, he (the chemist) will transmute and synthesise atoms as his elder brother has done molecules, with results to be wondered at and possibly even misused by his fellow creatures. I foresee a time, not immeasurably far distant, when it will be possible for us to synthesise any element whatever, whenever and wherever we please; alchemy indeed in the service of man."

Chemistry.

President : PROF. W. N. HAWORTH, F.R.S.

THE MOLECULAR STRUCTURE OF CARBOHYDRATES.

PROFESSOR W. N. HAWORTH'S address is a welcome synopsis of current views on the architecture of carbohydrates, the class comprising sugars and the various forms of starch, cellulose and vegetable gum. To their economic and alimentary importance must be added their significance in the development of organic chemistry, throughout whose course the attraction of their changes and the repulsion of their properties have afforded its practitioners a constant allurement. They are so closely interwoven in the fabric of this development that organic chemistry without the carbohydrates would seem as unsymmetrical as the Taj Mahal with only three principal minarets.

Since the death of Emil Fischer a substantial change in the structural presentation of sugars has been consolidated. Fischer's most notable activities in this field were directed towards elucidation of configurational problems, and although he did not exclude the possibility of a cyclic structure, in fact adopting it for the glucosides, common practice continued to represent the parent sugars by hydroxylated carbon-chains including an aldehyde-group (the aldoses), or a keto-group (the ketoses). It is these groups that lead to the glucosidic, or the oxide, ring. Haworth (1925) presented a structural

model of glucose in the form of a six-atom cycloid, and the supporting experimental evidence now accumulated is formidable.

By the new (amylene oxide) presentation, normal glucose and fructose are derivatives of tetrahydropyran, and are therefore denominated pyranoses, while the γ-isomerides are recognised as derivatives of tetrahydrofuran, and are classified as furanoses. This redisposition has been made without requiring to disturb the configuration of hydrogen atoms and hydroxyl groups previously distinguishing the hexoses, which are now identified by names recalling both origin and structure, *e.g.*, glucopyranose, mannopyranose, glucofuranose, fructofuranose, etc. From this groundwork, disaccharide-formation follows the two-fold course revealed by the properties of the products, namely, those (*a*) which retain a potentially free carbonyl group, *e.g.*, maltose, lactose, cellobiose, and (*b*) which have lost this feature, *e.g.*, sucrose, trehalose ; and it is now possible to identify the carbon atoms of each combining pyranose or furanose which is concerned in the union. For example, maltose-formation involves carbon atoms 1 and 4 of the two combining glucopyranose molecules, while sucrose arises by uniting carbon atom 1 of glucopyranose with carbon atom 1 of fructofuranose. This type of diagnosis has latterly been greatly extended, penetrating the obscurities of the polysaccharides inulin, cellulose, starch and xylan (wood gum).

The majestic edifice of carbohydrate chemistry now rising on the foundation so truly laid by Fischer, and to which Haworth and his collaborators have contributed very substantially, could not have reached its present ample proportions without the device of methylation, introduced by Purdie and Irvine (1903), and with suitable modification since applied to di- and polysaccharides. Crystalline tetramethylglucose heralded a long series of polymethylsaccharides whose physical properties are more helpful than those of the parent hydroxy-compounds ; they are easily crystallisable from organic solvents, show definite melting points, and in some cases may be distilled under greatly reduced pressure. It was from a study of tetramethylglucose and of its methylglucoside that the pyranose-form in hexoses and pentoses came to be verified ; and the survival of polymethylated hexose-units from careful hydrolysis of polymethylated di- and polysaccharides has vividly illuminated the structure of these elusively complicated materials. The address under review portrays in striking manner the combination of cellobiose-units in a continuous chain to form cellulose, and compares the latter with starch, correspondingly formed by combination of maltose-units.

The picture thus presented harmonises with the results of X-ray analysis, and a chemical estimation of the cellulose chain-length has indicated 200 glucose-units as the most probable approximation. Some explanation must therefore be given to account for the wide incongruity between this molecular weight and that indicated by physical methods, and in Haworth's view this is owing to natural cellulose consisting of aggregated chemical units, associated perhaps by co-ordinated co-valencies, catamaran-wise. Many of the changes incurred by cellulose in the laboratory and in industrial processes involve a disaggregation of the physical unit preceding chemical transformation into derivatives.

Elucidation of the starch-complex reveals corresponding general features. Methylated starches from three sources are uniform in the chain-length of their chemical unit indicating a combination of 25 glucose-units, while the physical method of molecular weight determination manifests a far higher value. As in the case of cellulose, this discrepancy may be explained by aggregation of chemical units, because, by a simple method, Haworth has prepared a disaggregated starch which, in the form of its acetyl and methylated derivatives, has the same molecular weight as determined alike by viscosity and by gravimetric assay of the terminal group. This disaggregated starch is not degraded, but is probably the chemical unit, capable of undergoing re-aggregation to physical assemblages of increasing viscosity. Glycogen specimens, on the other hand, with chain-lengths of 12 or 18 glucose-units, display little or no tendency to molecular aggregation.

The polysaccharides levan (from grass-leaves) and inulin, analogous condensation products from fructofuranose, are reviewed in the address, and lichenin (from lichen cell-walls) is shown to resemble cellulose in structure with a considerably shorter chain-length of about 80 glucose-units. Xylan (from esparto) has 18 or 19 xylopyranose-units terminated by an arabofuranose which can be removed intact, when the residual chain comprises only xylopyranose-groups. At least one method by which Nature effects

the synthesis of these complex molecules is indicated by reference to the constructive action of micro-organisms on solutions of glucose and other sugars, when the resultant polysaccharides are found to contain hexose-units in which, very surprisingly, the glucose-configuration has been changed. Finally, it is anticipated that advances in medical knowledge will arise from polysaccharides having immunological function, which are not simple in structure, and probably have a molecular weight exceeding 2,000.

It is unusual to find in the lay press a pertinent inquiry relating to carbohydrates but Dr. A. S. Russell, writing in *The Listener* (August 28, p. 361), asks why the *d*-glucose-configuration holds a unique place among the sugars. When there are sixteen possible distributions of hydroxyl groups and hydrogen atoms why, he asks, should the dice be loaded so heavily in favour of *d*-glucose ? It seems to suggest that Nature is not a communist. The question is well worth asking, and perhaps Professor Haworth will one day be able to answer it.

Geology.

President: PROFESSOR H. G. A. HICKLING.

SOME GEOLOGICAL ASPECTS OF RECENT RESEARCH ON COAL.

THE conception that coal is a metamorphic rock is ancient but evidence to establish this has been obtained only by recent researches. In the eighteenth century knowledge about coal was confined to the conditions under which coal had been formed—the *in situ* and drift theories of origin of coal—but little was known as to the nature and general mass of the rock itself. There was uncertainty, as to whether the major differences in coal were determined during the accumulation of the deposit, by the kind of plant materials and by their state of decay or whether the chief factor was the effect of physical forces brought to bear on the deposit after its burial in the crust. The recent researches of palæobotanists and fuel technologists have clarified these points to a considerable degree.

The uncertainty regarding the structure of the coal in earlier days was due to the difficulty of preparing thin slices for microscopic examination. Henry Witham in 1833 prepared sections of coal and from their studies William Hutton concluded that every variety of coal is of vegetable origin and the difference of the nature of these varieties has most probably arisen from an original difference in the nature of the vegetables of which they were composed. During the greater part of the eighteenth century progress in the study of coals was slow, though bleaching and macerating agents were used to elucidate the plant structures. The modern period of coal petrology is the offspring of the palæobotanical research of the nineteenth century and this work has given a precise knowledge of the structure of the plants which formed the coals and a clear picture of the condition of some of the coal peats at the time of their deposition. During this period the technique of microscopic examination and section cutting advanced rapidly due to the researches of Jeffreys Theissen, Lomax, Winter and Seyler.

Before the time of Witham and Hutton coal was regarded as a deposit from solution —a kind of vegetable extract, but microscopic examination limited this idea by revealing the abundance of organised plant structure in coals and the abundant presence of the characteristic " uniform brown substance "— the " lignitoid material " of Jeffreys or the " anthroxylon" of Theissen. Stopes classified the types of coal substance seen in bituminous coals and gave an account of their constitution as revealed by the microscope, and emphasised the laminated character of coal. Later researches have shown the abundance of plant structures in " coal substance " and that coal is a characteristic mixture of this " coal substance " and other ingredients. However the " uniform brown substance" could not still be resolved entirely and at present there are two views regarding the nature of this material. Some contend that it is entirely made up of plant fragments, while others suggest that a large part of the substance decayed to the condition of a true fluid which solidified as a structureless gel which acted as cement to the whole mass. Two distinctive features of this substance are the low ash content and little variation in its organic composition as compared with other constituents of coal. This substance may be called " Vitrinite ".

The other components of coal, though subordinate in quantity to vitrinite, determine largely by their varying quantities different varieties of coals. Chief among these is fusain or " mineral charcoal " formed from woody tissue and characterised by low hydrogen and oxygen content. The next group of coal components may be designated the " high hydrogen group ",

the outer coatings of stems, leaves and spores, which are characterised by an accumulation of waxes, fats and resins. Their presence alters the composition of coal specially in hydrogen content. There is still another ingredient of coal characterised by its minute state of fragmentation a sort of residuum to which Stopes has given the name—micronite. The cannels and boghead coals have different structures and have the distinctive presence of microscopic oil-bearing algæ—essentially similar to the living oil alga—*Botryococcus braunni.* The presence of this constituent has the striking effect of increasing the hydrogen content of these coals.

An examination of the types of coal aggregate shows variations in the quantity of coal components which possess different grain sizes. As the average size of the particles in any coal aggregate decreases, the proportion of vitrinite lessens while there is a corresponding increase of the "high hydrogen group" and the micronite, thus determining the exact quality of coal. Differences in coal have resulted not only by the type of aggregate but also by the degree of alteration (the rank of the coal) to which the original composition of the aggregate was subjected. There is considerable divergence of opinion in assessing the relative importance of these variable factors in determining the differences in the quality of coal. Chemically considered coal components consist mostly of carbon, hydrogen and oxygen,–these being marked variations in their hydrogen content. Representative analysis of bituminous coals shows the following limiting variations, hydrogen 4·5 to 6, carbon 65 to 90 and oxygen 5 to 30%. The variation in hydrogen content of these coals is largely determined by the character of the original materials but the carbon: oxygen ratio is determined solely by other considerations. It is this difference of oxygen content which denotes the rank of coal distinguishing the lignites, bituminous coals and anthracites.

Thus we see that the rank of a coal is the measure of the alteration in composition which the deposit has suffered in consequence of rise of temperature and increase of pressure resulting from burial in the crust. Observations on the relation between the rank of coals and their distribution in the rocks have shown that change of rank has been caused by geological factors and is quite independent of the original constitution of the seams. This relation is expressed by Hilt's law which states that "in any vertical section the deeper seams are of higher rank than the upper seams". Experimental evidence points to the fact that pressure is more responsible for inducing differences in rank rather than temperature. It is thus obvious that coal can be used as a combined "geological thermometer and barometer".

Zoology.

President: PROF. F. BALFOUR-BROWNE.

THE SPECIES PROBLEM.

PROF. F. BALFOUR-BROWNE in his address on "The Species Problem" questions the validity of Wallace-Darwin concept of the Theory of Natural Selection and comes to the conclusion based on an intensive study of the habits and structure of water beetles that Natural Selection plays but a small part in the origin of species.

The carnivorous group of beetles Hydradephaga and vegetarian group Hydrophilidæ affect isolated habitats which can be grouped as ponds, lakes and rivers and the beetles occupying any one of these habitats form a well-marked community. Each community under an intensive scrutiny reveals a large number of species. This has brought to light an interesting feature that the species composition of a community of insects affecting one habitat differs fundamentally from that of another.

The classification of the habitats into ponds, lakes, etc., is purely an arbitrary one as one passes into the other imperceptively due largely to the frequent changes happening in these habitats. It is interesting to note that a changing habitat is closely associated with a changing community.

Prof. B. Browne discusses further whether adaptation in response to a keen struggle for existence is an explanation sufficient to account for the origin of species. He cites a number of examples to suggest that choice plays a part not merely in determining the food of insects but that it also has a profound influence in the selection of the habitat and draws the inference that neither soil nor plant environment has any direct effect on the community. He suggests that the active factor must be the internecine strife of the animal population.

The purity of a community is usually maintained by the destruction of immigrants and at no time of the year do we find a general mix-up of the communities; for

even new generations seem to emigrate exercising a well-marked choice in the selection of their new habitats. The examples cited show that "Choice plays a part in the composition of these communities." If choice should account for localisation and distribution of species, an even more important rôle is suggested for choice in the study of biological races. By careful experimentation it is possible specially in the case of vegetarian species to induce the insects to develop a decided preference to certain kinds of plants so that we may ultimately succeed in getting at a race of beetles which restricts itself exclusively to that food plant. The changes of habit have not produced any morphological changes to any appreciable degree, though Cameron and Nuttal seem to suggest certain changes in the thickness and length of the antenna and the length of the legs of the insects due to changes in the feeding habits. Nuttal associated these changes with physiological influences.

A study of any group shows that species differ in their relation to one another. Some form clusters while some stand apart. The clustered species of water beetles are usually members of the same community or sometimes even inhabitants of the same districts. In the several examples quoted it is suggested that there is no interbreeding between the related forms and no intermediates have been recognised. However, it is suggested that some clusters may prove to be intermediates between biological races and species.

Prof. B. Browne's study of a series of insects with Deronectes depresses and D. elegans occupying the extreme ends with well-marked specific characters and with an equally well-pronounced geographical distribution may in due course offer an answer to the question whether the climatic or edaphic conditions have a control over species formation.

The inheritance of acquired characters is still a pious hope and proof of it is still lacking. The study of water beetles does not offer any evidence that species characters distinguishing pairs are really heritable. A study of other groups of animals shows that acquired characters do not disappear directly after the stimulus which caused them has been removed.

Work on Drosophila and Oenothera has shown that new characters may arise from changes in the chromosomes of germ cells and the question whether the ancestors of water beetles got into water by choice and then developed adaptive characters or did the changes in form and structure create the choice by reason of which these beetles took to an aquatic life, still remains unanswered.

An analysis of the characters on which classification has based shows that in some cases special structural modifications have enabled the insects to live in water while in others functional changes explain adaptation.

Prof. B. Browne suggests that the species characters are for the most part non-vital and some of the main characters from which the classification of Dystyscidæ is based show a progressive development. These are not vital to their possessors since the various stages in their developments exist side by side and natural selection could have nothing to do with their progress.

The chromosal theory of heredity points to a chromosal control of characters and the orthodenetic tendencies may be the outcome of mutations, caused by external stimulus. Some authors look upon directional evolution as an inherent problem of the organism. If function can cause variation in structure, these evolutionary lines may be responses to the physiological activities assuming that acquired characters are inherited. Inheritance of characters must also depend upon the effect on the germ-cell chromosomes of changes and habits, physiological activity and in the structure of the individuals. The chief struggle for existence seems, therefore, to be in the chromosomes which perpetually endeavour to maintain their normal constitution and relationship.

Geography.

President: PROFESSOR F. DEBENHAM.

SOME ASPECTS OF THE POLAR REGIONS.

THE remoteness of the polar regions from the centres of civilization, and the inhospitable conditions of their climate, no less than the dangers surrounding their approach had delayed their exploration until comparatively modern times; but with the scientific advances recently made in navigation, and with the perfection of equipment for long and dangerous voyages, the search for these unknown areas has been renewed with considerable success. The snowy skies and ice-encumbered seas must make stern demands on the physical endurance of voyagers, and evoke their most heroic

qualities, seldom witnessed under the soft-handed influence of temperate latitudes. In the fifteenth and sixteenth centuries, the motive inspiring the voyages into the unchartered frozen zones of the earth's surface was the desire to discover new routes to China and India for the expansion of trade, and new continents for the extension of territorial boundaries. Although the discovery of more favourable and easy routes to the East, and of new continents for economic development and colonisation, put the political interest in the polar regions temporarily in the background, their geographical problems continued to stir the imagination and the spirit of daring of the voyagers. It may not be the privilege of all geographers, nor even of all the intrepid explorers, to visit personally the drifting of ice-masses and blinding snow storms which surround the Arctic and Antarctic seas. It is, however, within the reach of all to obtain a clear and vivid picture of these strange and weird regions from the published descriptions of the explorers, the accounts of the Press, and the exhibition of motion pictures; and in the perusal of the rapidly growing literature of the polar regions, one is thrilled by the dangers encountered, and is fascinated by the courage and determination of the heroic explorers, so much that one rarely gets a comprehensive view of the territory explored as a whole. This strong human element inevitable in such works, appeals to the emotions of the reader and must account for regarding the polar regions as lying outside the real comity of the world. From the days of Pierre Bouvet and Martin Frobisher down to more recent times, the principal aim of the promoters of the polar expeditions has been one of ultimate gain in securing vested interests in hunting, fishing and mining, and the cryolite mines of Ivigtut and the ivory of primeval mammoths, the furs of seals and bears and the blubber of whales invested commerce in the North with a strange romance.

The story of Arctic adventure and trade has a grim and melancholy aspect in that several of their ventures have brought animal life in the polar regions almost to the verge of extinction. With the progress of long-distance aviation, the idea of using the northern latitudes for passenger and freight traffic in the air has become insistent, and if the greatly improved aeroplanes are diverted from their legitimate purpose, and are used to explore the possibilities of the wealth of animal products, fatal consequences will overtake the most interesting and valuable animals known to science. The cupidity of man and his unwillingness to co-operate are at the bottom of all international troubles. The wealth of the Antarctic and Arctic regions lies in the seas which surround them, which are free to all nations, but their claims to ice-covered land sectors without harbours and without any economic value, have been the subject of international negotiations which illustrate that there is always an aggressive and capricious spirit in international affairs. "It is probably too late for any alternative arrangement to be adopted, but had there been a League of Nations in existence at the beginning of the century, before any claims had been laid in the Antarctic, the protection and administration of this last and least useful continent would have been a most appropriate subject for League administration as an international park of vast proportions which should be open to all nations who would respect its amenities." The passion to possess Antarctic lands arises from the voyagers' tales of their untapped mineral resources and at the moment, nations are apt to forget that they are covered by thick ice-sheets or are rendered inaccessible by topography and climate. Professor Debenham concludes the section of his address relating to the economic survey of the polar regions, by expressing the hope that future developments in the science of physics and of engineering might enable man to harness the Antarctic blizzards and the great ice movements for generating power in the maintenance of industries when coal becomes scarce and oil exhausted, and all the water-power in the temperate latitudes is fully utilised.

If we ask ourselves why so many people have risked their lives in the past by going to the polar regions for other than economic reasons, the answer must be "the lure of the wide open spaces" with their immense solitary grandeur, and the irresistible spirit of curiosity to penetrate the unknown. There is the possibility of the holidays of civilised people, being taken nearer to the polar latitudes, with the increasing rapidity and safety of air transport, and it may not be a fantastic forecast that "there may be a Brighton of Spitzbergen, a resurrection of the Smeerenberg of two centuries ago". The consideration of the polar regions as a holiday resort for the citizens of crowded

cities raises the question of where health is best to be sought. It is true that the temperate zone, provided it is not too far from the sea, is perhaps the healthiest belt for man, but the polar regions are definitely the healthier segments of the earth's surface for the simple reason that the climate though bleak for man must be impossible for disease-bearing vermin. Apart from the healthiness of these regions, the value of their climate for curing diseases contracted in temperate latitudes is an aspect of geographical study worth investigation. Perhaps medical researches on the curative proportions of the air in the polar lands especially in pulmonary affections might yield results which would favour residence in them rather than in the Sanatoria of the Alps, and in such circumstances the polar regions have an importance to mankind far more valuable than all the industries they will ever support. This is an aspect of medical research which falls within the purview of international bodies such as the Rockfeller Foundation, which has done so much for remedial medicine.

Professor Debenham, referring to the value of polar explorations in regard to science, both pure and applied, pointed out that the subject of meteorology was likely in the future to gain most by a prolonged and intensive investigation in high latitudes. The phenomena of magnetism and aurora, which are akin to those of meteorology, are best studied in the higher latitudes which favour investigations of ionosphere. The science of geology, especially in its branch of tectonics though there must be difficulties in the study of rocks covered by sheets of ice, must be interesting the nearer one gets to the axis of earth's rotation. The geologists attached to the British Graham Land Expedition are engaged in the investigation in the Antarctic continent how and where the folded ranges of South America and Graham Land merge into or butt against the faulted escarpments of the Australian Sector of the Antarctic. The discovery of coal beds by Admiral Byrd's geologists, within 300 miles of the South Pole, and the controversies whether the Poles have shifted in the past and whether continents are drifting and other similar geophysical problems must keep the attention of geologists on polar lands. The biological problems of high altitudes, such as the drift of oceanic waters, the presence or abundance of plankton and the movements of the great animals, have already made rapid advances through researches conducted by the Discovery Committee over all the waters of the Antarctic ocean. The value of the polar regions as an outlet to the spirit of adventure and urge for exploration is psychological rather than geographical, and practically in all polar expeditions, the motive is a curious combination of an urge to test the summit of human qualities and a desire to accomplish a great deed for the sake of the deed itself.

The potentialities of these uninhabited zones are undoubtedly great and the interest in the polar regions is bound to become increasingly practical with the progress of our knowledge of the higher latitudes in all their multifarious aspects.

Engineering.

President: Mr. J. S. Wilson, F.C.G.I., Hon. A.R.I.B.A., M.I.C.E.

THE STABILITY OF STRUCTURES.

The meaning of stability is not easy to define. In dynamics and mechanics we have stability of steady motion and stability of equilibrium of position and of friction. In civil engineering it is usually applied to the power of a structure to withstand for an indefinite time all the loads and forces that may be brought to bear on it.

The great pyramids of Egypt, the tall brick chimney that stood till recently at St. Rollox in Glasgow, the masonry dams built across valleys to impound water and arches constructed across rivers and in great buildings are good examples of stable structures. The strength and stability of these structures depend mainly on the resistance to compression offered by the materials, *viz.*, stone or brick. In the case of the complimentary form of structure, such as a suspension bridge, they depend almost entirely on the tensile resistance of the chains or cables. In most iron and steel structures such as girder and canti-liver bridges the resistance of the material to both tension and compression contributes to their stability in equal proportions. In reinforced concrete the great strength of concrete to resist compression is combined with the power of steel to resist tension. Due to the facility with which it can be built and shaped it has been applied to many large structures which present problems in stability of considerable interest. Tunnels of masonry or brickwork and cast-iron lined tube tunnels, subject to the pressure of great depths of earth, are forms the stabilities of which are not easy to calculate.

In estimating the stability of a structure the principal factors are the strength or resistance to rupture of the material and the balance or direction of the forces or loads brought to bear on it. In structures subjected to prolonged stress the factor of safety is a vital consideration and the correct factor of safety to be adopted, in each individual case, has still not been accurately fixed and, so far as civil engineering structures are concerned, the advance made in this direction has not been very great.

The rupture or breaking down of a structural element by a force is dependent on the detail of its incidence and the resulting intensity of the stress induced in the material.

The conception of action of forces along lines was introduced at an early stage. The position of such a line with respect to the boundary of a member offering resistance governs the distribution and intensity of the stresses in the material. In estimating the intensity of stress the position of the line in a lamina of the part under consideration is usually considered and in it the distribution of the stress follows the "Trapezium Law" which is a particular case of Galileo's solution of the beam problem.

In a pier or buttress which supports and at the same time resists the thrust of an arch the line representing the resultant of the weight and thrust of the arch is deflected downwards by the weight of the buttress and the shape of the structure has to be so decided as to keep this resultant line of pressure as far as possible near to the centre of pressure so as to obviate very high concentration at one end or appreciable tension at the other.

This rule applies to all cases of masonry such as ordinary walls, abutments, piers, retaining walls, dams and arches.

In this connection the problem of the masonry arch which is very interesting deserves special mention. The arch form of construction has been known for thousands of years and several magnificent arches built by the Romans are still in very good state. Although the arch form of construction was generally used there was always a feeling of uncertainty as to their strength and stability.

Up to the first half of the 19th century knowledge of the strength and characteristics of materials and of applied mechanics was not sufficient to establish or disprove the accuracy of the various theories propounded from time to time and any efforts made in the problem depended almost as much on dialectics as on mechanical principles. Throughout the 18th and 19th centuries mathematicians tried to find the exact form of the line of thrust that would ensure equilibrium in a mass of masonry bridging a void bounded by the horizontal line representing the road on the top and the intrados of the arch at the bottom shaped to conform to the line sought. The effect of hollow spaces over the haunches was investigated also and the influence of a moving load was regarded as negligible.

The correct shape of the arch to be adopted was also a point in dispute and the indefiniteness on this point was so great that about the year 1759 a controversy arose between the two designs submitted by two persons, Mylne and Gwyn, for a bridge, across the Thames at Blackfriars, one with an elliptical arch and the other with a semi-circular arch, and it was held that elliptical arch was stronger than a semi-circular one contrary to the every-day experience of the egg being weaker along the sides than on the ends.

Differences of opinion on the correct proportions of an arch also were very sharp. Some maintained that the thickness of an arch at the crown should be proportional to the radius of curvature while others held that the span of the arch should be the governing factor.

These contradictory opinions of the people who were considered to be authorities on the subject did not help architects and engineers who went on taking additional precautions by binding stones with iron cramps and for many years architects and builders were extraordinarily lavish in their use of cramps even in places where they could have no beneficial effect, notwithstanding the fact that these cramps did more harm than good to structures by corrosion.

Fine masonry arches of 300 feet span have been built. The construction of arches of larger spans has been made possible by improved technique in building. For longest spans reinforced concrete has now superseded masonry and arches with spans as great as 590 feet have been constructed.

In his monumental work called *Grandes Voutes* Paul Sejourne has given particulars of all arches of appreciable size throughout the world with details of construction and comparative analysis of the proportions. But the mathematical theory of the stability and strength of the arch, however, is of comparatively recent solution, due mostly to eminent engineers like Unwin and

Rankine. It may be added that Rankine's mathematical treatment of the subject has been further developed by his pupils, Alexander and Thomson.

The problem of the stability of masonry dams had exercised the minds of engineers and mathematicians for many years and the failure of the Bouzey dam in France in the year 1895 gave prominence to the subject. The maximum pressure on the masonry was the only factor considered in calculating its proportions in designing it and it was held by some that the failure was due to its incapacity to withstand the great tensile stress brought to bear on it and by others due to shearing. After the disaster, the French Government introduced a regulation that on horizontal joints of dams there should be a vertical compressive stress at the water face equal to not less than the water pressure at the joint. In 1904, Prof. Karl Pearson and Mr. Atcherley published a memoir entitled "Some Disregarded Points in the Stability of Masonry Dams" in which they stated that although a dam might satisfy the usual conditions regarding the stress on horizontal planes, it might still be subjected to dangerous tensile stress on vertical planes in the vicinity of the down stream toe. But the elaborate and careful experiments held jointly by the late William Gore and the President on these points showed no evidence of the tensile stress at the down stream toe; the shear stress diagram was practically a triangle with the maximum at the down stream edge and the vertical stress distribution agreed substantially with the Trapezium law. These experiments helped to re-establish the confidence in the method that had been in use for estimating the stability of masonry dams. During the last few years, investigations, both experimental and mathematical, of problems relating to the design of concrete dams and curved dams have been made in the United States. The influence of heat, both natural and that generated by the setting of cement, on stresses and stability has received much attention.

The suspension bridge is a fascinating type of structure and there have been astonishing occurrences in the course of the development of its design and stability. Suspension bridges formed of strong flexible climbing trees or roots have been used by primitive people. Examples made of wrought iron appear to have been in existence in the eighteenth century. Telford's famous bridge across the Menai Straits with a span of 570 feet completed in 1826 and one built across the Thames at Marlow by W. Tierney Clerk, F.R.S., in 1829 are still in use. The former is of the simple suspension type; the latter was the first to be built with stiffening girders. A supposed improvement was introduced by a Mr. James Dredge in 1836, which was much applauded and several bridges were built according to his specifications, some in England and some in India, all of which however failed. These failures created a strong prejudice against suspension bridges of all kinds and retarded their development.

The flexibility of the suspension bridges under heavy moving loads is a source of trouble and of wear and tear of the platforms. Nevertheless, when the chains are pulled by the loads into a line of equilibrium, so long as the anchorages are secure and the towers are sound, the stability depends solely on the tensile strength of the chains, and under these conditions almost all suspension bridges have a substantial margin of strength or stability. If over-loaded, long before the rupture of the chains would occur, the sagging or deformation of the platform would act as a warning. Where the ultimate strength depended mainly on the resistance to compression of the platform, as in Dredge's bridge and others built about the same time, the failure by the buckling would be sudden and disastrous.

In the modern suspension bridge the stiffening girder is as important a feature as the chain or cable and its introduction has made it possible to construct the gigantic bridges in the United States. The latest example is of a span of 3,400 feet. Cables composed of thousands of steel wires, four times as strong as iron, take the place of iron chains and the flexible timber platform has been replaced by deep steel stiffening girders with upper and lower decks providing double tracks. Instead of the stability of the structure being a matter of dispute and of the extraordinary uncertainty as before, the stability is now determined and gauged by calculation based on applied mechanics.

Anthropology.

President: SIR ARTHUR S. WOODWARD, F.R.S.

RECENT PROGRESS IN THE STUDY OF EARLY MAN.

SIR ARTHUR WOODWARD'S address on the recent progress in the study of early man is a

condensed account of the researches leading to the establishment of a number of genera of prehistoric man known to-day. Sir Woodward is admirably fitted for his task, being not only an anthropologist but a geologist and a palæontologist as well.

Any history of early man is closely bound up with the history of mammals associated with him as well as the implements he used. And a correlation between these three factors is a study which has often received scant attention and the more than usual interest in the address lies in the fact that Sir Arthur Woodward has taken all these facts into consideration in adjudging the value of the different human remains.

The most significant fact that has emerged out of the studies on fossil man is that man did not originate in Europe and the fossils known from this continent belonged to men who were immigrants from some other region. The investigations of Sir W. Boyd Dawkins on the mammals associated with early man in Europe have all pointed to the same conclusion, that they are immigrants from the Arctic regions, from Asia or from Africa. Africa as the home of early man is known only by a single skull of uncertain age named Australopithecus by Prof. R. A. Dart in 1925. While this skull which belongs to an ape certainly shows more human characters than does that of any other existing ape, a complete account of it is still being expected. It is on the other hand more likely that the origin of man is to be traced to Central Asia and the geographical distribution of the known fossils of early man is quite in consonance with this view.

The geological age of Eoanthropus from Sussex is the most difficult to determine but a close examination of the nature of the stratum as well as the mammals that occur associated with this fossil goes to show that Eoanthropus belongs to the beginning of the Pleistocene age. The difficulty is much less in the case of *Protanthropus heidelbergensis* which was found in association with mammals typically lower Pleistocene and it is the general opinion that it is unlikely that there is much difference in age between the Piltdown and Heidelberg men.

Pithecanthropus, discovered in Java, has been said to belong to the beginning of the Pleistocene period. The more recent Sinanthropus found in a cave in China and associated with a number of characteristic mammals and even with the remains of fires, seems to have been a contemporary of Eoanthropus and dates back to the early Pleistocene period. This latter skull is important in that it combines the characters of the other skulls.

Geologically latest is the Neanderthal or Mousterian man and this marks a fresh stage in the history of the evolution of man, since by this time man had learnt to bury his dead. Later discoveries of the Neanderthal man in Palestine have definitely enabled us to think that here is the modern man in making.

Dealing with the fossil remains of man found in other continents Sir Arthur Woodward points out that the fossils found in Australia relate to a fairly advanced type of modern man, as Australia was separated from the rest of the world throughout the tertiary age. The fossils in North America are also recent and relate only to the later part of the Pleistocene age. The work of Dr. Peter Wilhelm Lund in South America also points to the same conclusion.

Physiology.

President: PROF. P. T. HERRING, M.D.

THE PITUITARY BODY AND THE DIENCEPHALON.

THE address is devoted to considering the anatomical and structural features and the functional activities of the pituitary body which until recently was an organ of great speculative interest. In 1832, its dual mode of origin was discovered, the gland being composed of a ventral evagination of the twixt brain (the nervous lobe) and an epithelial accession (Rathke's pocket) from the buccal cavity. This union of buccal epithelium with the nervous element appears indeed to be to some extent a symbiosis, a view which is supported by experiments of transplantation. The coming together at an early stage of development of the pituitary body of two hollow processes, the one from the dorsal surface of the buccal cavity and the other from the ventral wall of the diencephalon throws light on an obscure point in the evolutionary history of the vertebrates, containing perhaps a suggestion that the union denotes an old association between the alimentary canal and the nervous system not unlike what occurs in the invertebrates. Thus Rathke's pocket may be regarded as the vertebrate representative of ancient invertebrate mouth (Palæostoma) and a comparison of the pituitary body with the ascidian subneural gland as homologous structures is often

made in Zoological works. The history of the pituitary is one of great significance, and the epithelial components make up the greater part of the organ in all vertebrates, forming the pars glandularis (anterior lobe), the intermedia (intermediate lobe) and pars tuberalis (tuber cinerium). The fourth part, pars nervosa, is the derivative of the twixt brain.

The anterior lobe contains chromophobe cells (mother cells), which make up the greater part of pars intermedia,—which are able to give rise to acidophil and basophil cells. There is evidence to show that chromophobe cells with filamentous golgi networks give rise to acidophil cells and those with perinuclear golgi rings, to basophil elements. The relative proportion of these cells is liable to variation in the different parts of the pituitary and also in the same part under different physiological conditions. The histological character of the pituitary can be varied and changed rapidly.

The epithelial lobe, whose circulation is sinusoidal, provides for its secretion to enter the blood directly, which is obviously destined more for general purposes in the body than for action localised to its immediate neighbourhood. The posterior lobe (pars nervosa) contains granular particles, derived most probably from the epithelial investment and the ependyme cells and secretes the pressor substance and other hormones which in their activities do not differ from the extracts of the epithelial lobe. The secretion of the posterior lobe may be absorbed into the blood vessels, penetrate the adjacent nerve floor and also enter the cerebro-spinal fluid.

The pituitary body is closely bound up with the floor of the third ventricle, and non-medullated nerve fibres arising from cells in the supraoptic, paraventricular and inferior hypothalamic nuclei have been traced to pars intermedia, pars tuberalis and islands of epithelium in the pars nervosa, besides sympathetic nerve fibres and the carotid plexus. Experimental work supports the view that the nuclei in the diencephalon exercise a controlling influence upon the secretion of the pituitary, as is shown by the observations on the female rabbit, the removal of whose pituitary within an hour after copulation (but not later removal) prevents ovulation. An injection of the extract of the anterior lobe brings about ovulation, and it is reasonable to infer that the stimulus of mating induces reflexly in the rabbit sufficient hormone for the purpose in about an hour's time. Zondek refers to the pituitary sex hormone which sets the reproductive cycle going, and Harvey Cushing comments that the emotional self-starter resides in the diencephalon. Evidence is accumulating that the hypothalamus (comprising the tuber cinerium, copus mammilare, infundibulum and pars nervosa of the pituitary body, optic chiasma and subthalamic tectal region) is an important site of integration of the basic activities which are common to the life of all vertebrates. The pituitary body is an essential part of hypothalamus which controls the metabolism of solids and water, with its accompaniments of hunger and thirst, the regulation of body temperature, emotional reactions, sleep, mating and reproduction.

Hormones have been separated in more or less pure form from the anterior lobe which stimulate growth and exercise a controlling influence over many important organs of the body, the glands, thyroids, parathyroids, thymus, cortex of the suprarenals and the mammary glands. The gonadotropic hormone is probably a product of the basophil cells. Harvey Cushing and his co-workers have drawn attention to the changes in carbohydrate metabolism which are exhibited by patients and experimental animals in hyper and in hypo-pituitary states, and injections of anterior lobe extracts have been found to produce ketonuria, lipæmia and cholesterolæmia, in addition to hyperglycæmia and increased resistance to insulin. The posterior lobe furnishes an extract pituitrin which contains two active principles, a pressor substance (β-hypophamine, vasopressin or pitressin) and a substance acting upon uterine muscle (α-hypophamine or oxytocin). The hormone of the posterior lobe extract which produces a diuretic action, probably resides in vasopressin. Harvey Cushing expresses the view that the grey matter in the hypothalamus, possibly the nucleus supraoptics is an important cell station for the integration of nerve impulses regulating water intake and output, and that the hypothalamus and the posterior lobe of the pituitary body make up a neuro-epithelial structure, the parts of which are mutually interdependent in their functions. A multiplicity of actions can be evoked by the extracts of the posterior lobe but it is doubtful if all of them are normal functions.

The diencephalon and pituitary body form a working unit, having functions of far-reaching importance in the control of fundamental physiological processes. It is probable that the pineal body is another part of the same mechanism, but its functions are still obscure.

Psychology.

President : DR. LL. WYNN JONES.

PERSONALITY AND AGE.

DEFINING personality as an integration of all the marks of mind and body as affected by nature and nurture, Dr. Wynn Jones presents a most interesting review of recent attempts to correlate it with age. He accepts five great classes of factors in personality, namely: (1) intellect, (2) disposition, (3) temper, (4) temperament, and (5) character, regarding them as largely, but not entirely, independent variables in the weaving of personality. Difficult as are the qualitative aspects of the problem, their quantitative assessment presents at the moment almost insuperable obstacles, because among other fogs enveloping the subject, recognition of the onset of senility is astonishingly variable. The German investigator, Giese, lately invited newspaper readers to declare the age at which they first noticed signs of advancing years, and to specify the signs: analysis of the replies placed the average at 49, but the age varied with the individual from 18 to 82! What can you do with that?

This inquiry, although doubtless amusing to the newspaper readers, does not strike the layman as contributory to the investigation, because while some people notice the passage of years by disabilities of the body, others are more impressed by changes in the mind. Moreover, in the latter class, 38 per cent. recognised their increasing age by treatment received from associates, while 44 per cent. relied on self-diagnosis: it is curious to note that the remaining 18 per cent. resisted the suggestion of senescence altogether, some with indignation. Whether contributory or not, however, it does illuminate the complexity of the subject, compared with which the study of child-psychology, a happy hunting-field for psychologists during the past thirty years, is almost child's play. Nevertheless, attempts have been made to extend, with suitable modifications, the methods of child-psychologists to the subsequent five or six decades of human life, and some of these are helpfully reviewed by Dr. Wynn Jones.

Among them is E. L. Thorndike's *Adult Learning* (1928), which examined the changes in (1) amount, and (2) nature of the ability to learn displayed between 15 and 45, especially between 25 and 45. One definite outcome is that nobody under 45 need shrink from trying to learn in the belief that he is too old to learn. This is good news for the opsimath, or late learner, and an authoritative encouragement of university extension courses. "If he fails in learning it, inability due directly to age will very rarely, if ever, be the reason. The reason will commonly be one or more of these: He lacks and always has lacked the capacity to learn that particular thing. His desire to learn it is not strong enough to cause him to give proper attention to it. The ways and means which he adopts are inadequate, and would have been so at any age, to teach him anything." Here psychology confirms commonsense, and in this connection there should be noted a conclusion of W. R. Miles, namely, that when speed is the stressed element in an intelligence test for adults, then the decrement due to age is greater than it is when power in unlimited time is emphasised.

Quantitative results are more easily obtainable in the athletic field studied by Professor Charlotte Bühler (1933) to ascertain the effect of age on various motor abilities, from which it appears that those demanding a maximum expenditure of energy per second are associated with the youngest average age, while older athletes excelled in exercises demanding economy of effort and its optimum distribution. Thus the following scale emerges:—sprinters and long-jumpers (23·5); hurdlers, high-jumpers, pole-vaulters and weight-putters (24·5 to 25·5); long-runners, rowers, weight-lifters and hammer-throwers (25·5 to 31·0). In group sports distinguished from individual contests the sequence was:—boxers (21·9); wrestlers (22·3); footballers (23·8); hockey players (26·4); tennis players (28·5); polo players (up to 50). To these Dr. Wynn Jones adds (for 1934) cricketers (30 for batting, 30 for bowling; 34·5 for those exceeding 3,000 runs) and golfers (35 as the median age of the forty who headed the open championship; and 31 as the median age of thirty-seven open champions since 1894).

One of the most baffling and least easily

measured factor in assessment of personality is temperament, *i.e.*, as defined by psychologists, the influence, direct or indirect, of bodily metabolism upon the psycho-physical processes of the nervous system; but the address does not expand this vitally important element. In passing, it may be questioned whether this definition of temperament coincides with common acceptance, the above-mentioned influence in the lay mind being that exerted by general health, while temperament usually connotes a predominant quality, as in 'lively temperament,' or 'phlegmatic temperament'. An appreciation of the recently published *Diary of Robert Hooke* (*Nature*, September 7, p. 358), to which Professor Andrade has gracefully brought his wit and erudition, makes it clear that Hooke, "generally allowed to have been one of the greatest promoters of experimental natural knowledge, as well as ornaments of the seventeenth century" (Richard Waller), was a permanently sick man, victimised by chronic inflammation of the frontal sinuses. Nevertheless he passed the sixty-seventh year, but the temperamental effect of his disorder, his crooked figure and his shrunken limbs cannot be computed; how confusing to the age-personality connotation, therefore, would have been his treatment by modern therapy. Every middle-aged man can recall from individual experience unfortunate examples of personality influenced by health; so much so that the benevolent minded, in contact with a thoroughly objectionable temperament, instinctively seek a physical explanation, and commonly find it.

Another factor in personality not merely unexpanded by Dr. Wynn Jones, but even unmentioned, is matrimony. To the Indian observer this may not seem important, because in this country (*a*) to remain unmarried is most unusual, and (*b*) matrimony appears to present less variable impingements on personality than among Western peoples. In the other hemisphere quite a significant proportion of people with personality inviting study remain unmarried, while those who do venture on matrimony cannot escape a modification of their personality, sometimes profound, owing to its influence. This is perhaps more conspicuous in the United States, but it is easily recognisable elsewhere. Reduced to a simple form, this factor would involve examination of the woman's personality in addition to the man's, a complication giving fresh terror to this branch of psychological inquiry—or further attraction, according to the age and personality of the investigator.

Botany.

President: F. T. BROOKS, M.A., F.R.S.

SOME ASPECTS OF PLANT PATHOLOGY.

BIFFEN'S discovery that susceptibility and resistance of wheat varieties to yellow rust are inheritable characters, led plant breeders to evolve new varieties of crop plants, which while retaining the valuable commercial qualities of the older crops, would resist specific diseases. Genetical and selection methods have led to the successful control of certain wilt diseases but in certain cases the plant breeder is faced with almost insuperable difficulties, since there is often complete or almost complete linkage between susceptibility to a specific disease and high quality which is extremely difficult to break. Another problem which the plant breeder has to face is the fact that one crop is liable to attack by several diseases and resistance to one disease is transmissible independently for each specific disease. Again he has to reckon with the fact that a variety bred for resistance in one locality may become susceptible if transferred to a different environment.

Parasitic organisms are liable to evolutionary change just as their hosts are and one cannot therefore postulate that their parasitic proclivities will remain constant over long periods of time. New physiologic forms evolve both by hybridisation and by mutation, and this capacity of micro-organisms to change, introduces enormous complications into the problem of disease control.

Another advance in the control of plant diseases lies in the greater attention now paid to plant sanitation or plant hygiene. Such preventive treatment, following the same lines as in medical and veterinary sanitation, aims at the abolition of the sources of infection wherever possible. The efficacy of plant sanitation is best seen in intensive cropping in fruit plantations and under glass. For instance, by preventing the fungus *Stereum purpureum* from spring within and on the confines of fruit plantations, risk of Silver-leaf disease is appreciably reduced.

Seed-borne diseases are controlled by fungicidal treatment of the seed before sowing, the control of some epidemic diseases by spraying the shoot system with fungicides, and the

protection of wounds in woody plants against parasitic invasion have met with a considerable degree of success.

More care is now paid than formerly to growing plants under the best environmental conditions with a view to diminution of parasitic attack, including modifications of cultural practice which tend to favour the host at the expense of the parasite. The ecological study of disease in plants is only in its infancy, but it promises to be one of the most fruitful aspects of plant pathology.

Another branch which is receiving much attention at the present time and which will probably assume greater importance in the future is the influence of one micro-organism on another in the establishment of disease.

The effects of associations of micro-organisms in culture are often profound. A mixed culture of two organisms can often produce a result which neither of them alone can induce. Such an effect has been termed "synergism" by Holman and Meekison. One organism may change the substratum so that it becomes suitable for the growth of the other, but the interactions of the two associates on the original medium are sometimes of a more intricate nature.

The effect of micro-organisms on one another is frequently also one of antagonism. Two organisms may mutually inhibit the development of each other, or one may be greatly impeded in its growth by the other. In the latter case one organism may exercise some toxic influence on the other or it may utilise the available food material so rapidly as to starve the second organism. Factors of this kind may perhaps play an important part in the specificity of saprophytism exhibited by certain fungi.

Of particular interest and of great importance is the antagonism shewn by certain saprophytes to pathogenic fungi which invade the underground parts of their hosts: indeed it is not too much to say that a new chapter in soil microbiology has been opened with the recognition of this factor of biological antagonism. In 1923, Millard demonstrated that *Actinomyces scabies*, a commonly occurring soil organism which causes potato Scab, could be prevented from attacking potatoes by incorporating large quantities of green manure in the soil.

During the early development of plant pathology little attention was paid to the study of disease in plants of a functional kind, *i.e.*, to disease not induced by parasitic agency. In certain ways non-parasitic diseases of plants are more difficult to investigate than those due to parasites, and not much progress can be made with the elucidation of some of them until more is known about normal plant physiology. Warrington and Brenchley startled the botanical world some years ago by demonstrating that boron was an essential element in the proper nutrition of certain green plants. Since then Brandenburg has suggested that boron-deficiency in the soil is the cause of the serious "heart-rot" disease of sugar beet and mangolds. Another element having the property—formerly unsuspected—of exercising an important rôle in the nutrition of some plants is manganese. It has long been known that oats did not thrive on certain soils unless salts of manganese were added. On such land the oats were stunted in growth, the leaves were affected by grey blotches, and the plants died prematurely, the disease being known as 'grey leaf' or 'greyspeck'. Small amounts of manganese sulphate applied to the soil enabled a healthy crop to be grown. Samuel and Piper have shewn by careful experiments that minute quantities of manganese must be available in the soil to allow of the normal nutrition of oats and certain other plants. Such a disease as that of 'grey leaf' of oats is now known as a "manganese-deficiency" disease. Another interesting example of the importance of nutritional factors in the maintenance of well-being in crop plants is afforded by the researches of Storey and Leach on a grave disease of tea bushes in Nyasaland, which causes chlorosis and rapid death. They have demonstrated that this disease is due to insufficiency of available sulphur in the soil.

Educational Science.

President: DR. A. W. PICKARD-CAMBRIDGE, D.LITT., LL.D., F.B.A.

EDUCATION AND FREEDOM.

THE address is devoted to examining the two opposite tendencies at work in the world of modern Education; the one, a tendency more or less antagonistic to freedom and the other, a tendency laying claim to freedom in ways which it is not always possible to defend. The latter is reflected in a number of educational theories which

would so far as possible exclude discipline from life in the supposed interests of free development, and also in a certain impatience with all forms of authority, manifested by the younger generation. But the other tendency is the outcome of the political doctrines adopted in countries such as Russia, Germany and Italy, where we witness a complete subordination of the individual to the State, not only in his external life and action but also, so far as education and propaganda can achieve it, in thought and will. In all the three countries the method adopted is the same, namely, anything which runs counter to the ideas promulgated by the dictator is sternly discouraged. This phenomenon is not confined to Central Europe and its manifestation even in democratic countries is discernible. The great feature of party government in England is party discipline, which essentially deprives the individual of all freedom of action and speech, and the members of the party have to subordinate their opinion and will to the interests of the organisation to which they might belong. Naturally the schools managed by such parties will gradually acquire the rigidity under which the political organisations conduct the public affairs.

Some of the recent works in fiction such as Aldous Huxley's *Brave New World* and H. G. Wells' *The Shape of Things to Come* which are most popular with the younger generation, clearly envisage and apparently approve the political and educational systems based upon the complete elimination of individuality. "Democracy," says Wells, "asks people what they want; what is required is to tell them what they want and see that they get it." His new government was meant to rule not only this planet, but the human will. It is open to treat such works as fiction but the events of our own times show that the constructors of imaginary Utopias are almost prophetic. It has been shown in most countries that it is possible so to educate and to govern as to eliminate freedom of thought and life and to make human beings efficient cogs in an all-embracing machine and to convince them that that is the best life for them. The acceptance of such views in the political organisation will lead to a passive acquiescence of them in the field of education, with the consequence that the curricula of studies, the methods of imparting instruction and the teachers and pupils must come under a thorough-going espionage.

But is it not a fact recognised and practised from ancient times that individual freedom, subject to such a minimum of restriction as is necessary for life as a member of a community, is the indispensable condition of a good and even tolerable existence? Plato and Aristotle thought that it was the business of education to bring up young citizens in what they called the 'Spirit of Polity' and it makes all the difference in the world when Russia, Germany and Italy substitute the word 'State' for 'Polity'. Where the State assumes the authority for directing and controlling education, the result must inevitably be a standardised and unresisting mentality, which education in the spirit of a polity of free men and women must above all train them to think freely and accurately and to desire to carry the results of their thinking into action. Such a freedom includes the power of the individual to realise the good, as he understands it, in his life, and the power to take an equal share with any other citizen in determining the action of the community in the realisation of public good as a whole. So far as the community is concerned, the ideal state will be a democracy in which every individual is free to realise the highest values, physical, moral and spiritual; and the realisation of some of these is only possible if he can enter into freely determined mutual relations, with others, participating fully in the life of the community, communicating his share of good to it, receiving his share of good from it.

Freedom desired for the individual encounters obstacles of more than one kind; and it is in a great measure with these that education has to deal. They are partly in himself, partly in the community. The powers of an individual to make a free and correct choice from out of the lower and higher values, obviously depends upon the training, as well as upon his natural endowments. Every one is greatly hampered by the effects of heredity, and by the influence of early environment. The whole process of education is to set the higher values before the immature mind in such forms as it can understand and encourage the habit of choosing them. The importance of such discipline depends upon the fact that without it, the immature personality may not discover that it has the freedom, to choose something other than that which immediately appeals to it. Discipline, correction and guidance reveal the power of choice; in

time self-discipline follows and freedom to pursue and realise ends or values increases. Much of the discipline imparted by education in the cause of freedom is apt to be counteracted by the faiths, prejudices and party feelings of the community. The interests of communal organisation do not always coincide with those of education and more often than not, the purpose and intentions of education are vitiated by personal rancour and malice of those entrusted with its management.

It must be remembered that before life is far advanced the simple problems and issues of early life are merged in far more complicated issues of the community, requiring the utmost clarity of thinking. For effective thinking the younger generation should have access to truth about facts and the mind should have been disciplined in the habits of working accurately and honestly. If freedom in political and private life is to be preserved, those who educate young men must put them in the way of obtaining truth about facts and of distinguishing truth from falsehood in what is presented to them and in their own reasoning. It is in this way that they can be trained to citizenship in democracy and to the conception that it is less a system of equal rights than a system of equal responsibilities and co-operative endeavour for the good of the community as a whole.

Dr. Pickard-Cambridge examines the relative values of the school subjects which afford opportunities for the formation of habits of careful and correct judgment. The task of the teacher is to encourage his pupils to think by the presentation of evidence or of opposite points of view; the desire of the politician is to prevent his adherents from thinking so that they may swallow his particular notions. It is in the school room that the dangers of dependent, unventuresome and servile mentality must be countered. Young people are much more likely to think for themselves within the framework of school discipline (which is scarcely felt so long as it is wisely controlled) and do think for themselves. Dr. Pickard-Cambridge next proceeds to observe how the system of public examinations as they are at present planned and conducted, militates against the results of education.

The suggestions made in the Presidential address as regards educational theory and practice are no matters merely of finance, administrative and political convenience, but of vital and immediate urgency if we are not unconsciously to bring up a race, which with its mind stunted, its capacity for freedom undeveloped, will fall an easy prey to the politician, the journalist and the dictator: and that if a free democracy is to continue, we must educate for it, for in many respects, the present educational practice is better calculated to produce a servile and passive mentality than to evoke an activity of mind and freedom of judgment worthy of free men and women.

Agriculture.

President: J. A. VENN, LITT.D., F.S.A., J.P.

THE FINANCIAL AND ECONOMIC RESULTS OF STATE CONTROL IN AGRICULTURE.

THE Presidential Address of Dr. J. A. Venn before the Agricultural Section of the current year's session of the British Association for the Advancement of Science deals not with any aspect of the service or practice of agriculture but, as the above title indicates, with some of the economic factors upon which the prosperity of agriculture is coming to depend more and more in recent years. It does not seem to matter how high or low efficient one's production may be, it is really, on the other hand, the price one's produce is able to fetch that is the deciding factor. This would indeed be a truism hardly worth stating were it not that in the modern state the prices of commodities are not regulated in the way known to economists by the interaction of demand and supply in a world market but by a whole battery of protectionist weapons, both offensive and defensive, whose result cannot be foreseen and which have to be constantly changed and adapted to varying conditions. It is the story of how Great Britain leaves off her *laissez faire* free trade policy and falls into line with the universal protectionist tendencies of the world, to what extent this change of policy has brought relief to agriculturists, what the cost has been to the State Exchequer, how conflicting interests like those of the home producer, manufacturer and the Empire producer, or again those of the consumer, middlemen, landlord, tenant and agricultural labourer are sought to be served and what a variety of purposeful measures of State action these have introduced—it is the story in fact of their new economic regime of the latest convert to protectionism and State control that Dr. Venn unfolds in his address. Frankly, he plays the rôle of only an

'expositor' and gives us little more than a narrative of these developments together with a picture of their historic background without attempting any criticism of the merits or imperfections of the measures or offering any suggestions or alternatives, or developing any particular theme or view. He alludes, however, in passing to various dangers and risks to which this kind of elaborate artificial propping by means of State control and aid may in time lead. It is not difficult to see that his sympathies are with the old-time free-trade policy and that like most British people he looks upon these measures as a necessary evil, perhaps only temporary in character to give place in time to the free play of natural forces whose result will admit of a reasonable amount of forecasting and of suitably providing against. He quotes the following dictum uttered recently by one of the world's dictators:—"What the situation calls for is the free movement of goods, of people, of capital and of credit," and adds that "We in these islands have more to gain than any other nation by such a consummation." This consummation is, we are afraid, a long way off, and will like the horizon keep moving farther and farther as long as nations can set no limit to their ambitions of conquest and domination, political or economic.

In his historic survey, Dr. Venn traces the close parallel that exists between the remedial measures against the depression at various periods including the present one and that many mistakes and much needless expenditure of money could have been avoided if only this parallel had been better known. The results of successive acts of amelioration by the State during the past are described, such as the wiping out, by remission of a big load of agricultural taxation, the provisions for the better housing, education and health of rural workers, the institution of small holdings and the provision for agricultural research and technical instruction for the farmers. Attention is also drawn to the change in the farming methods that has proceeded side by side with this State action, by which the British farmer turned from arable farming to the more remunerative fields of dairying, the production of fruit, vegetable and other foodstuffs of a luxurious character. The story is brought down to the period of the Great War and the rigid State control of agriculture necessitated by that crisis. Into this, however, the address does not enter, for Dr. Venn's main theme relates to the peace time activities of the thirteen-year period subsequent to 1922, during which the new measures of State aid and protection have been in full blast. He divides those thirteen years into two distinct periods, the first one being the period of subsidies, grants-in-aids and reliefs from taxation, and the second that of the control of home production and of imports accompanied by the imposition of protective duties. The several measures under the first are duly catalogued, their features being only broadly indicated, and the monetary gain to agriculture itemised and estimated. The estimate is interesting and is as follows:—wheat deficiency payments, £ 7,180,000; sugar-beet subsidy, £ 2,820,000; meat subsidy, £ 3,300,000; milk grants, £ 1,600,000; small holdings and allotments grants, £ 900,000; afforestation grants, £ 450,000; ministry of agriculture and development commission, £ 2,500,000; tax remissions, £ 15,000,000;—making up a total of £ 33,750,000. A deduction of £ 10,250,000 is made on account of payments by statutory wages by farmers bringing the total net gain to British agriculture to £ 23,500,000. The result has been an increase in the acreage of wheat, a new and prosperous beet sugar industry, an increase of 50% in milk cattle and so on, all of which may be taken to justify the expenditure incurred by the new policy. Dr. Venn points out in this connection that the chief beneficiaries of these grants have been the tenant-farmers and agricultural workers, but not the landlords, whose position has continued to deteriorate. But the landlord's wail is a familiar cry all the world over, for the tendency throughout has been to assist the actual farmer, be he owner or tenant, and to take little notice of the mere rent-collecting owner, and even in England, the drastic step of State ownership of all land with a system of granting land on a cultivating tenure has been proposed by land reformers.

The second set of measures comprises the restriction of imports, improvements in home marketing methods for capturing the home market, the enactment of marketing Acts, and trade agreements fixing export quotas from foreign countries. The increase in price brought about by these measures, Dr. Venn estimates at some £ 17,000,000 of increased receipts to the producer, which added to the gain from the

direct grants and remissions, brings up the total gain to agriculture to £ 40,000,000. In respect of these measures too, Dr. Venn refers to the almost revolutionary break with the age-long British tradition implied by the powers granted under the marketing Acts, whereby "co-operation" is made "compulsory". Mention is also made of the irksome red tape, supervision and interference by officialdom which one has to put up with, not to speak of the penalties and fines imposed for infraction of the Act. All this is no doubt true, but the bulk of even the latest opinion is solidly in favour of a continuation of the various subsidies (including the much-debated sugar beet subsidy), the milk 'pools' and the various other measures of State control. The nation is evidently quite willing to pay this price for the well-being of its agriculture.

There is, we cannot help noting, a strong under-current of disapproval of these measures running throughout the address which does little justice to the aims in view or the unavoidable difficulties that beset their attainment. When all is said and done, British agriculture cannot adequately feed the British people, and there was a time when hardly a quarter of her food requirements was produced within her limits and it is a well-kept war-time secret that during the winter of 1917–18 food stocks had run so low that proud and wealthy England was perilously near starvation. Such a situation, it would obviously be suicidal to allow to recur and it is not difficult to appreciate the outlook of British statesmen. To enable British agriculture to support her population out of her own resources if possible or supplement by Empire resources if necessary, is evidently the objective; to gain this end all these superhuman endeavours are being made. Dr. Venn himself testifies to the results that have already been achieved in the desired direction and this should be the justification for the vast sums being expended for the pursuit of the economic 'heresies' and the unwelcome encroachments of the State on the liberty of the individual. One wishes, on the other hand, that here, in India, our own Government would accord to Indian agriculture a suitable measure of similar support and financial help.

Conference of Delegates of Corresponding Societies.

President: PROF. P. G. H. BOSWELL, F.R.S.

THE PRESERVATION OF SITES OF SCIENTIFIC INTEREST IN TOWN AND COUNTRY PLANNING.

THE study of the regional aspects of geography is intimately connected with the consideration of the safeguarding and appropriate preservation of sites and objects of scientific, historical and archæological importance and interest in the course of town and country planning. In 1924, Prof. J. L. Myres discussed the problem of the conservation of such sites and indicated four categories of objects worthy of preservation. In pursuance of the resolution passed at the Conference of Delegates, the Council summoned a meeting, the outcome of whose deliberation was that all learned societies should take concerted steps to promote legislation wider in scope and more strictly worded than the Ancient Monuments Act. Formerly the success of efforts directed to the preservation of sites and objects of scientific interest was due to the enthusiasm of advocates and the broadmindedness and public spirit of landowners and benefactors. While this work will, it is hoped, still continue, a large share of power is now in the hands of the people, who must possess sufficient knowledge as a requisite for useful action.

How can the British Association, and in particular the Corresponding Societies, inform the people and assist them to safeguard their national memorials?

The frequent references in the public press to this and cognate subjects indicate the people's awareness of the necessity and desirability for preserving sites and objects of scientific interest. The creating of public opinion must depend upon making known such objects and the information regarding all such sites is still incomplete. So far as Botany or Zoology is concerned no systematic attempt to compile a list was ever made in any country, but by the exertions of the Geological Society, a valuable list exists. If all the learned societies could co-operate in the preparation of a complete list of sites and objects of botanical, zoological, geological, historical and archæological interest, and communicate their results to the British Association, consideration of steps to be taken to secure legislative protection, will become easy and effective.

There are two aspects of preservation which might appear conflicting. Beauty spots and magnificent sceneries must always be accessible to the public and must be preserved from the encroaches of agriculture and industries. These are nature reserves. There may be a few spots possessing both scientific and æsthetic aspects, as for instance the area surrounding Downe in Kent, and when the Town and Country Planning Act is applied to this country, there is obviously a clear case that the planning should not be allowed to obscure the scientific and æsthetic interest associated with Darwin and Lord Avebury. The British Correlating Committee for the Protection of Nature submitted in evidence before the National Park Committee in 1929, a comprehensive list of areas where nature reserves are most required. In East Anglia there are a number of scenic types not exemplified elsewhere in Britain, and the whole place is littered by sites of such geological and archæological importance that the interest in the study of Pliocene and Pleistocene geology and in the records of pre-historic man has always attracted bands of students for study and research.

It may be recalled that in 1797, the discovery of palæolithic implements from Hoxne near the country boundary of Suffolk and Norfolk led to investigations revealing the great geological and archæological interest of the succession of ancient lake-deposits and early human industries, with the result that Hoxne has proved to be unique in Britain on account of the detailed evidence that it affords of inter-glacial climatic fluctuations. Another equally interesting place is the Gipping Valley-system north-west of Ipswich which has yielded a series of sub-crag rostro-carinate implements and flakes and a succession of human industries in the succession of glacial and post-glacial deposits. The Derby Road, which disclosed an inter-glacial lake-area similar to that at Hoxne is all but lost to Science.

Professor Boswell concludes the address with a significant observation that "Our duty as trustees for the future lies clear before us if only we adopt the view, that by acting now to safeguard sites of scientific interest, we are in effect taking steps to preserve some of the very title-deeds of our intellectual possessions."

Chemotherapy of Malaria.

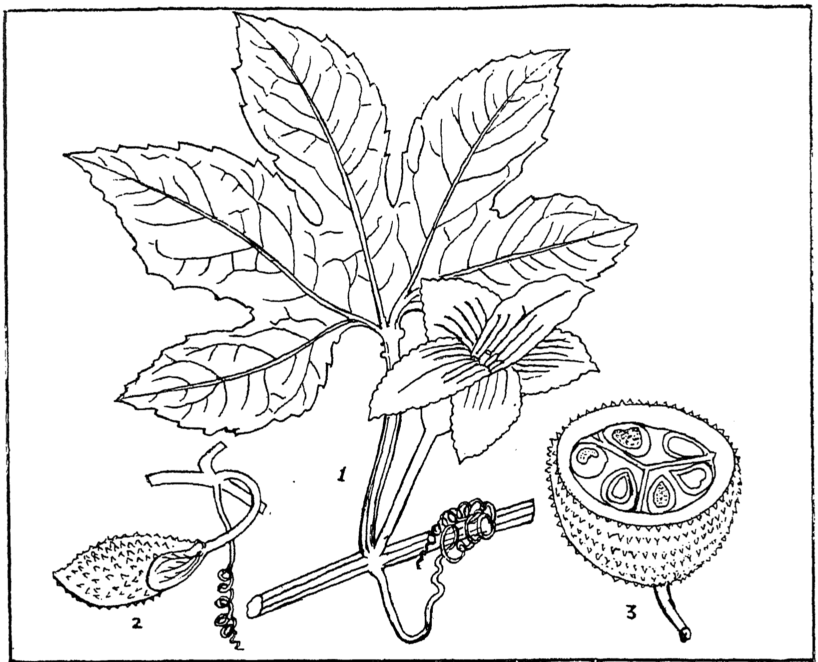
AT the recent session of the British Association, a discussion was held on the chemotherapy of malaria. Lt.-Col. S. P. James, F.R.S., in opening the discussion said, "The British Empire, with its vast malarious territories in the tropics, is more concerned with the provision of effective anti-malarial drugs than is any other nation in the world.

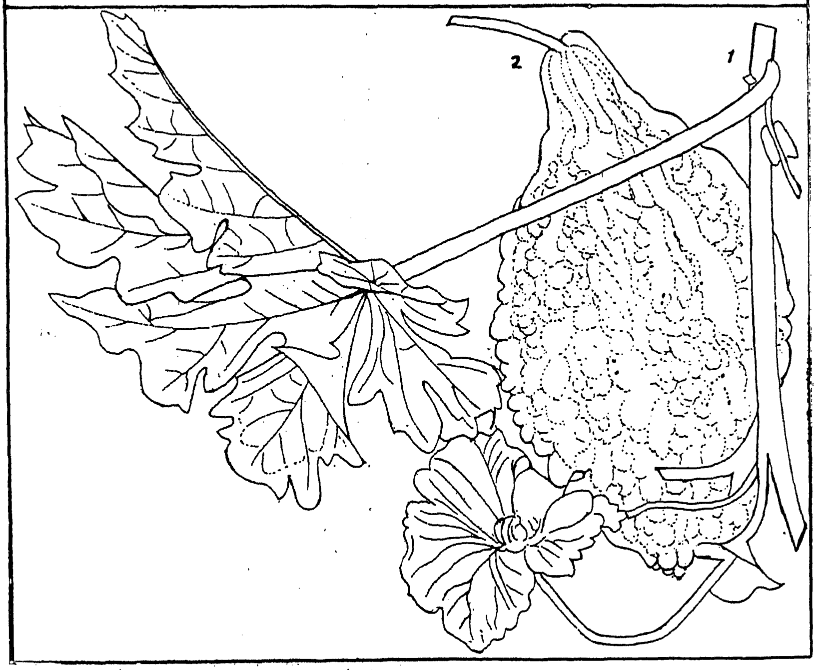
"Until recently the alkaloids of cinchona bark were the one and only effective remedy available. These natural products, however, are not effective for certain therapeutic purposes, particularly for true causal prophylaxis, the prevention of relapses and the prevention of spread. The aim of chemotherapy is to find preparations which will be effective for those purposes.

"Two remarkable synthetic anti-malarials, namely, plasmochin and atebrin, have been discovered and prepared on a large scale in Germany and their merits and defects for the particular purposes mentioned are now being assessed in the laboratory and in the field. Their discovery has given a great stimulus to chemotherapeutic work."

Lt.-Col. James gave an outline of methods and plans which are being tried or have been suggested for extending anti-malarial chemotherapy research in England, "where as yet it has been entirely neglected by the chemical industry and has received almost no financial assistance from Government or other sources."

Momordica cochinchinensis Spreng.





Momordica charantia Linn.

PLATE II.

the lime is deposited over a cellulose skeleton. This branched skeleton shows stratification of cellulose also when $CaCO_3$ is dissolved in dilute HCl (Fig. 5). As in the former species cystoliths occur in the lower epidermal cells which are much enlarged in size as usual.

In the cells of the basal hairs of *M. cochinchinensis* we also find deposit of calcium carbonate in a circular group (see Fig. 6). But here lime is not deposited on a skeletonic structure of cellulose and hence they are conveniently called pseudocystoliths. In the

other genus of Cucurbitaceæ similar deposit of lime in the leaves may be found—as for example, in the upper epidermal cells of the leaf of *Cephalandra indica* Naud, there is a considerable deposit of calcium carbonate. Such heavy deposits often impart dotted appearance on the leaf surface and give an impression of gland dotted structure (see Fig. 7). It seems that heavy quantity of lime (calcium carbonate) is deposited in these plants during the process of metabolism. According to Haberlandt[3] the deposit of calcium carbonate may be redissolved by the plant when the system demands it.

As mentioned before, lime in the form of calcium oxalate crystals is present in stems and petioles of Momordica (*M. charantia* and *M. cochinchinensis*). Most of the crystals are solitary. They are of rhombohedral types belonging to the monoclinic system (see Figs. 2, 3, 4, 6, (B), Plate I). Numerous other crystals of monoclinic system in the form of twin or clustered crystals are also deposited in the stem and petiole of these species (see Figs. 5, 8, 9, 10, (B), Plate I). Twin crystals (star-shaped) and combination of monoclinic and tetragonal system with crystals of other different structures making complex or composite forms have also been observed in the petiole of *M. charantia* (see Figs. 13, 15). Twin crystals are mostly present in the petiole, though a few may be found in the stem. The star crystals of *M. charantia* differ from those of *M. cochinchinensis* in having more projected and prominent star ends (compare Figs. 8 and 16). The crystals in *M. cochinchinensis* are less numerous and smaller in size than *M. charantia*. In both of these species the crystals are completely absent in the roots. In the stem they are more distinct and larger in dimensions. They are scattered everywhere in the ground-tissue and are absent in the epidermal cells and very scantily present in the vascular bundles.

If we trace the crystals of Momordica from the petiole to the leaf blade through the midrib we find that the size of the crystals is gradually reduced and thus the shape is not prominent, so much so that they are not distinguishable even under the higher power of a microscope, hence the term "dust crystals" are applied to them. Upto half of the midrib these crystalline dusts may be traced but beyond that they are invisible.

[3] Haberlandt, G., *Physiological Plant Anatomy*, 1924.

It is to be remembered that sufficient amount of calcium oxalate is manufactured in these plants as a product of metabolism. Prof. Haberlandt remarks that oxalic acid is formed in the plant body as the result of a variety of metabolic processes particularly in connection with protein synthesis but this substance is poisonous to the protoplasm and is accordingly rendered innocuous by combination with calcium to form the very insoluble oxalate of the metal; calcium must therefore be present in the plant in heavy quantity. According to some Plant Physiologists[4,5] calcium oxalate which is an excretory product may be redissolved by the plant when there is a deficiency of calcium food.

I am indebted to Mr. K. Biswas, Superintendent, Royal Botanic Garden, Calcutta, (Offg.), for favour of his kindly going through the paper and making valuable suggestions.

Chimera in Pineapple.

By I. A. Sayed, B.Ag.
Government Farm, Kumta.

A PINEAPPLE plant exhibiting the combined characters of the two varieties, *viz.*, Queen and Kew (Smooth Cayenne) grown on the Kumta Farm (North Kanara) was observed recently growing in a plot. A critical study of the same was undertaken with a view to differentiate the outstanding characters and ultimately determine its possible origin. The following are the most important distinguishing characters in which the plant was found to differ prominently from the existing two types.

The leaf margins like the Queen are armed with conspicuous spines but the surface resembles very closely the leaf surface of the Kew which has a distinct brown centre along its entire length with green edges. The leaf surface of the Queen, however, has a uniform reddish brown colour to about half the length, the base being greenish. The leaf margins of the Kew are perfectly smooth.

The tendency of the chimeric plant towards the production of 'seed' (planting material) has been found to be similar to that of the Kew which is a very shy bearer of suckers and more so of slips. The Kew variety produces on an average two suckers but instances of plant producing slips are very few and far between. The Queen pine, on the other hand, bears suckers and slips freely, often profusely; the average being four and five respectively.

The fruit and the crown consisting of cluster of leaves resemble very closely the fruit and the crown of the Kew, particularly in the colour of the 'eyes' which is deep purple. The contrast lies in the crown leaves, the margins of which are spiny like the Queen. It may be pointed out here that at the final stage of ripening of the fruit, all the 'eyes' not only showed a perceptible increase in dimensions but had completely flattened thereby giving the fruit a striking resemblance to the fruit of the Kew.

The foregoing distinguishing characters of the plant lead to the conclusion that the exposition of the plant in the present form is mainly due to the combination of characters of two distinct varieties and, therefore, it is difficult to determine its right origin.

However, the only possible explanation of this phenomenon is that the present chimera seems to have arisen from the Queen so far as vegetative characters are concerned, while the fruit gives a clear indication of its source from the Kew. And, since these have combined in a bud sport, it is reasonable to presume that the two types, *viz.*, Queen and Kew, must have arisen from a common stalk retaining the potentiality to mutate in either direction, *i.e.*, towards Queen or Kew when conditions were favourable.

Man and Woman.*

THE recent work of Havelock Ellis, *Man and Woman* which ostensibly sets forth to examine the leading characteristics of man and woman from the biological standpoint, provides an admirable background for the exposition of socio-economic problems. The fundamental point on which the main thesis is developed is that it is possible to regard the determination of sex as independent of any possible intervention by sex chromosomes, and also to recognise an essential sameness of sex in all organisms, the sexes being due to the action of two opposed sets of influences, one tending to produce the characters called female, the other tending to produce the characters called male. Apart from the physical structural differences, men and women usually display traces of dispositions belonging to the opposite sex, while it is not uncommon that the play of these traits may result in a physically homosexual condition. This conception of men and women underlies the doctrine of the entire equivalence of the sexes; and the investigation of the secondary and tertiary sex characters tends to point out that the unequal and unlike values are, in all their differences, of equivalent weight. Secondary sexual characters, supposed to be the product of sexual

*"Man and Woman". A Study of Secondary and Tertiary Sexual Characters. By Havelock Ellis. (Eighth Edition, Revised.) [William Heinmann (Medical Books) Ltd., London, 1934.] Pp. vi+469. Price 10*s*. 6*d*. net.

selection, are those obvious characters which render the sexes attractive to each other, while the tertiary characters which are not usually so obvious, and which may not be confined to only one sex, are generally predominant in one sex, such as height, stature, the structure of internal organs and the differences of endo-skeleton. There is a complete review of the anatomical features and physiological differences of man and woman, based on the conclusions deduced from scientific and statistical investigations, and the mass of information contained in the twelve chapters devoted to the treatment of the subject is simply prodigious.

The present knowledge of men and women can only tell us what they are under the influence of civilisation, but cannot tell us what they might be or what they ought to be; and even a precise knowledge of the degree of their modifiability will not enable us to limit the respective spheres of men and women. Men are more variable and women are more precocious involving greater rapidity of growth and its early arrest; these facts have consequences of wide significance. The whole physical and psychic organism of the average woman is unlike that of the average man, on account of this fact alone. Another fact of equally far-reaching character is that the average man diverges to a greater extent from the child-type than the adult woman. It may almost appear paradoxical to state that the growth of man, from about the third year onwards, is to some extent growth in degeneration and senility, through an absolutely necessary adaptation to environment, and that the human infant presents in an exaggerated form the distinctive characteristics of humanity, *viz.*, the large head and brain, the small face, the hairlessness, delicate bony system and enlarged endocrine glands. In many respects women remain somewhat nearer to children than to men, to that extent they occupy a higher scale in the line of evolution.

The facts of physical and psychical organisation of women have a profound practical bearing on the spheres of activity into which they are entering in increasing numbers. They are an important industrial factor, although a large portion of them may not remain as life-workers. Apparently, as a sex, they seem to lack both a man's ambition and his disinterested mental curiosity. Because of the possible transitoriness of their engagements, it is difficult to estimate the force and soundness of their disposition to be trained for skilled and responsible positions. At present, it is only in Scandinavia that women as a sex seem to be demonstrating any aptitude for the more skilled branches of technical work and obtain employment on equal terms with men. This is largely due to the fact that the economy of reproduction under improved conditions has given greater freedom to women and conferred on them a greater control of their own energies. The activities of men and women in all gainful occupations are bound to become competitive and their harmonious and wholesome relationship must depend in all such adaptations upon the preservation of the fundamental and natural constitution of each sex. The doctrine of the equality of the sexes led to unregulated industrialism, with consequences most injurious to women as is reflected in the condition of the physical and mental health of women labourers.

It seems fairly certain that women are not going to outstrip men or even to equal them, in the fields in which men are certainly successful. It is only in one country that they seem to be rising to the most responsible type of position and that country presents conditions both unusual and abnormal—Russia.

We have read this book with great pleasure. The interest of the book extends far beyond the limits of biological implications of sex. The study of secondary and tertiary sexual characters opens a new field of investigation of the social and economic problems, and their readjustment and final solution should not be subordinated to political doctrines.

The book is a profound philosophical treatise on the most fundamental human problem in its varied and complex aspects, and the clarity of vision, scholarship and above all the total absence of prejudice and conventional formulas which distinguish its pages are a contrast to the common-place literature on the subject of sex. Havelock Ellis is a wise thinker and his outlook may even be conservative, but his contributions to contemporary thought on psycho-physical subjects are marked by deep sympathy and wise scholarship. His *Man and Woman* is undoubtedly a great work and students of Anthropology, Sociology, Economics and Politics will find in it a wealth of information such as few books can provide.

Research Notes.

The Zeroes of the Riemann Zeta-Function.

RIEMANN conjectured that all the complex zeroes of $\zeta(s)=\sum_{n=1}^{\infty}\frac{1}{n^s}$ where $s=\sigma+i\,t$ lie on the line $\sigma=\frac{1}{2}$. No one has proved, till now, that the above famous conjecture is either correct or false. Extensive calculations of numerical kind have, however, shown that the conjecture is true for t lying between 0 and 300 and that the function has 138 zeroes in the above interval. Recently, Dr. E. C. Titchmarsh [*Proc. Roy. Soc.* (*A*), 1935, **151**, 234] has extended the numerical calculations by developing suitable formulæ and has found that the Riemann conjecture is true for t lying between 0 and 390 and that all the zeroes in the above interval, 195 in number, lie on the critical line $\sigma=\frac{1}{2}$. He has also presented some theoretical considerations on the problem of the zeroes.

Combined Influence of Electric and Magnetic Fields on the Line Spectrum of Helium.

THE effect of crossed electric and magnetic fields on the line spectrum of Helium observed by W. Steubing (*Sitzb. d. kgl. Preuss. Akad. d. Wiss.*, 1935, pp. 1–16) has already been described in these columns (*Curr. Sci.*, 1935, **4**, 114). We may now notice the effect of coaxial electric and magnetic fields. There are a number of alterations in this case also, but the broadening of the Stark effect components does not occur. The Zeeman effect and an alteration of the intensities of the Stark components are observed.

I. Doublet separation is found only in s-components while the p-components (see III however) remain sharp and unaltered.

II. The sharp series shows a sharp Zeeman effect. The principal series is midway between the sharp and diffuse series in its behaviour.

III. In the diffuse series we have the null component (p and s) due to the magnetic field as a new line in place of the intense Stark effect pattern, and here the s-component becomes a doublet. The actual Stark components are present in the higher series members with low intensity, but their positions and relative intensities are as in the normal Stark effect, but the s-components all become double. The combination lines produced by the electric field vanish.

IV. With an electric field of 45,000 v./cm. and a magnetic field of 20,000 Oersted only the strongest Stark components of the diffuse series are faintly present. But with a magnetic field of 10,000 Oersted, the null line, which is very strong in the above case, vanishes while the normal Stark effect components are present.

The alterations in intensity are less important than in the case of crossed fields.

T. S. S.

The Relation between Atomic and Cosmic Constants in the Expanding Universe.

IT is now well known how Eddington has tried to bring about a relation between the dimensions of the atom and of the Universe in his theory of the fine structure constant. H. Ertel in the *Sitzb. d. Preuss. Akad. d. Wiss.*, 1935, deduces a relation between Einstein's cosmological constant λ, Newton's gravitation constant denoted by the author by the letter f, the proton mass m_+, the electron mass m, which is as follows:—

$$\frac{f\,m_+^2\,mc}{\pi h e^2}=\pm\sqrt{\lambda}$$

where c is the velocity of light, h is Planck's constant and e is the electronic charge. This result is deduced from Einstein's cosmological field equations and Friedman's differential equations which represent Lemaitre's theory of the Expanding Universe, together with a generalization of an equation given by Eddington.

If l_p and l_e are the de Broglie wavelengths of the proton and the electron ($=\frac{h}{m_+c}$ and $\frac{h}{mc}$) respectively, the above equation can be written in the more symmetric form

$$f\,\frac{m_+m}{e^2}=\pm\,\pi l_p\sqrt{\lambda}$$

$$f\,\frac{m_+^2}{e^2}=\pm\,\pi l_e\sqrt{\lambda}$$

With the numerical values $h=6\cdot547\times10^{-27}$ erg sec., $c=2\cdot998\times10^{10}$ cm./sec., $e=4\cdot770\times10^{-10}$ e.s.u., $m=9\cdot00\times10^{-28}$ grm. $m_+=1\cdot662\times10^{-24}$ grm., $m_+/m=1847$ and $f=6\cdot65\times10^{-8}$ dyne cm.^{2}/grm.^{2}, $\frac{1}{R}\frac{dR}{dt}=a$ (the Hubble factor) is calculated on the basis of the above theory to be $1\cdot812\times10^{-17}$ sec.$^{-1}$ while the experimental value is $1\cdot811\times10^{-17}$

sec.$^{-1}$ with an uncertainty of 20%. a is connected with λ by the equation

$$\frac{1}{R_0^{\,2}} + \left(\frac{a_0}{c}\right)^2 = \lambda = 3\left(\frac{a_\infty}{c}\right)^2$$

where R_0 = the equilibrium radius of the Universe and a_0 and a_∞ are the values of a for R tending to 0 and ∞. The theory gives $a_0 = 1 \cdot 134 \times 10^{-17}$ sec.$^{-1}$ and $a_\infty = 1 \cdot 833 \times 10^{-17}$ sec.$^{-1}$.

T. S. S.

Passivity of Gold.

THE resistance of gold to ordinary reagents and atmospheric influences has been traced to the formation of an adherent film of oxide on its surface. On the other hand, the anodic passivity of gold has been a matter of some controversy. Müller and Löw (*Trans. Far. Soc.*, 1935, **31**, 1291) have extended their "Surface Layer Theory" (Bedeckungstheorie) of passivity for gold electrodes. They have examined gold electrodes, under a reflection-polarisation microscope, when subjected to electrolysis in hydrochloric acid, taking care to protect the electrodes from convection currents. Simultaneous measurements of the current density have also been made. The surface at first appears dark under crossed nicols, and after a certain interval of time during which the current passes, it becomes bright. Corresponding to this latter stage when the current density falls, a diffuse layer of crystalline deposit is observed. The results show that gold exposed to air becomes coated with an oxide layer which is removed during anodic passivation in concentrated hydrochloric acid. An adherent film of the metallic salt now takes the place of the oxide layer. Discharge of OH^- ions at the anode can give rise to a 'secondary' oxide film. When the solution is well stirred the film of the metallic salt is easily disturbed. The natural oxide coating on gold is very stable and dissolves only in strong (5N) hydrochloric acid. The 'secondary' layer produced during anodic passivation is much less stable and disappears quickly even in dilute acids. In 5N hydrochloric acid, the 'secondary' layer formed, is dissolved out even during the passage of the current. The oscillations in current density when electrolysis is carried out are due to the alternate formation and dissolution of the film. The work of Müller and his co-worker brings out the close analogy between the behaviour of gold and of other metals less 'noble'.

M. P. V.

The Effect of Magnesium Deficiency on Crop Plants.

THE response of various crops to a deficiency of magnesium in the soil is described as the result of experiments conducted at the Massachusetts Agricultural Experimental Station by A. B. Beaumont and M. E. Snell (*J. Agri. Res.*, 1935, **50**, No. 6). Plants sensitive to magnesium deficiency developed characteristic physiological symptoms which have value in diagnosis. Chlorosis of the older leaves developed in the intravascular tissue. In the leaves with parallel veins this produced a striped appearance while in plants with a netted venation, a mottled pattern was produced. Curling of the leaf margins and marked necrotic areas also appeared in certain plants. Buckwheat and spinach were most affected, and turnips, mangels, corn and tobacco considerably so. The small grains, grasses, clovers and potatoes were only slightly affected. The addition of magnesium sulphate to the soil increased the percentage of magnesium in the plant or portions of it, the increase being greatest in the plants which were most affected in yield or appearance by a magnesium deficiency. It appears that to avoid magnesium deficiency a soil should contain from 30 to 40 parts per million of easily replaceable magnesium or 60 to 80 pounds per acre.

Pollination Studies in Toria and Sarson.

CROP improvement work relating to the two most important oil seeds of the Punjab *viz.*, Toria (*Brassica napus* L. var. Dichotoma Prain), and Sarson (*Brassica campestris* L. var. Sarson Prain) with particular reference to the special features of their pollination undertaken at the Lyallpur Agricultural College by Ali Muhammad is described (*Indian J. of Agr. Res.*, 1935, **5**, Part II). In both crops, cross fertilisation appears to be the usual method in nature chiefly through insect agency. Attempts at selfing under bags yield very poor results; in the six years' trials on the average only 12·3 and 20·3 per cent. respectively formed pods and many of these were not normally developed. The high self-sterility is surmised to be due not to external causes alone but internal causes also such as self-incompatibility. The explanation is suggested that the self-pollen is subject to an inhibiting action by the stylar tissue which makes it of slower growth than foreign pollen. The

observations also indicate that the inhibiting action is not equally effective in flowers of different ages, the secretion responsible for the action being produced actively between one to two days before and after flowering. Inbreeding and pure lines being thus of no economic value, group breeding has been resorted to and considerable improvement is reported to have been achieved already by mass-selection. It is stated as the result of hybridisation studies that self-fertility behaves as an inhibited character independent of the colour of the seed and that self-compatible brown seed plants have been evolved.

Spiral Structure of Chromosomes.

IN three papers of the July number of the *Proceedings of the Royal Society*, London, C. D. Darlington has described the detailed spiral structure of chromosomes in the several species of Fritillaria, and has deduced certain generalisations regarding the internal mechanics of chromosomes. The first paper [*Proc. Roy. Soc. Lond.*, (B), No. 807, 33], may be regarded as the general part where the broad features of spiral structure are described. The meiotic chromosomes possess both the major and the minor spirals and the first meiotic telophase, the major spirals relax to form relic spirals and by further expanding their loops form superspirals. The minor spiral does not relax. In the ensuing prophase the chromosomes contract and the relic and super-spirals disappear. The second metaphase chromosomes show similar spiral structures. During somatic mitosis only the minor spirals are present. The metaphase chromosomes show the threads very compactly coiled, while during the resting stage and during the later stage the threads divide. The nuclear cycle in mitosis shows that older coils are generally uncoiled externally while new coils are formed internally. In this respect prophase is a continuation of telophase and not a reversal of it as is usually supposed. The usual interpretation of the split nature of the metaphase and telophase chromonema are regarded as inconsistent with the spiral structure and with genetic and cytogenetic data. Several general assumptions have been made the chief of which are that the spiral arrangement is determined by a compensating molecular change, that there is a hysteresis or lag in the adjustment of the external form of the chromosomes to its internal molecular stresses and that paired chromosomes and chromatids on this account develop a "relational coiling".

In the second paper [*Proc. Roy. Soc. Lond.*, (B), No. 807, 59] a special study of the meiotic pairing in Fritillaria has been made. Pairing in this genus is incomplete and is liable to fail in parts attached to the nucleolus and the unpaired parts become relationally coiled. In fifteen species, pairing is interrupted very early and is therefore confined to the proximal regions. This leads to the localisation of chiasmata. The interruption of pairing is presumed to be due to the division of unpaired parts.

In the third paper [*Proc. Roy. Soc. Lond.*, (B), No. 807, 74] the relationship between chiasmata and the relational spiral is dealt with in detail. Three species of Fritillaria, *F. Elwesii* with intermediate localisation, *F. Meleagris* with extreme localisation, and *F. impirialis* with free distribution, have been studied. In the first two species the pairing is incomplete while in the last one it is nearly complete. Chromosomes remain associated at diplotene stages by chiasmata in the paired regions and by relational coiling in the intercalary unpaired regions. This can be understood if it is presumed that coiling occurs throughout the chromosomes but is replaced by chiasmata in the paired regions. In most organisms this replacement is nearly complete, but in diploid organisms with localised chiasmata and in triploids, coiling survives.

Dominance in Poultry.

A PRELIMINARY report of experiments of R. A. Fisher intended to throw light on the nature of dominance observed in certain well-marked breed characteristics in domestic poultry has recently been published [*Phil. Trans. Roy. Soc.*, 1935, **225** (B), 195]. The paper gives detailed data for the three factors responsible for crest, polydactyly and barred plumage.

The belief of Darwin and earlier writers that hernia was connected with the crest was abandoned by geneticists early in the 20th century on inadequate evidence but from his experimental data he has been able to conform completely with the view that crest and hernia are due to the same gene. This view also explains other significant features in the data; notably the complete absence of grown birds showing hernia without crest and the linkage relations with the Polish comb and with Pile.

Polydactyly when introduced into the wild jungle fowl is a typical example of the mutations with intermediate heterozygotes in which dominance is absent. The heterozygote is distinctly variable and occasionally overlaps the normal homozygote.

Barred plumage is more nearly a recessive than a dominant mutation; the heterozygous males are more like the wild than like the barred homozygotes. The barred hen when young is indistinguishable from the heterozygous male. The barred mutation thus introduces a sexual differentiation and when this sexual differentiation does not exist barred may be described as a dominant.

The three factors reported in this paper bear out the suggestions that the supposed "dominants" found in domesticated breeds of poultry show distinct lack of dominance when introduced singly into a wild strain. Any dominance shown by them in breed crosses must be due to modification during the period of domestication.

The Development of the Vertebral Column in the Haddock (*Gadus æglifinus*),

IN this contribution to our knowledge, a set of new observations is made on the vertebral column of the Haddock by A. J. Faruqi (*Proc. Zool. Soc. Lond.*, Part II, 1935, 21). The perichordal sheath forms the centrum of the vertebra in *Gadus* unlike in *Herring* where the notochordal sheath participates in it. The basi-occipital region is a composite structure incorporating in it an 'intercalary' neural arch. As opposed to the tetrapoda, the posterior zygapophyses take their origin from the centrum itself. Confirming the observations of Stannius, it is noted that the spinal ganglia in the trunk region become divided into two,—an upper accessory ganglion and a lower spinal ganglion and these two are connected together by a commissure.

On the Post-Embryonic Development of the Respiratory System of *Dialeurodes dissimilis* (*Homoptera, Aleurodidæ*).

BESIDES Fuller's pioneer work on the post-embryonal development of the tracheal system of termites, not much work has been done on this important problem. M. L. Roonwal gives us an account of the post-embryonic development of respiratory system in *Dialeurodes* (*Quart. J. Micr. Sci.*, 1935, **77**, Part IV, 605). The author points out that the number of spiracles in the nymphal instars is 4 and the tracheal system consists of paired ventral- and dorsal-longitudinal trunks. Tree-like branches arise some of which of course atrophy,—the final number being 156.

Larval Stages of Trilobites from the Middle Cambrian of Alabama.

C. G. LALICKER'S (*Jour. of Palæo.*, **9**, No. 5) observations on the Trilobite Fossils from Alabama show a series of changes in the larvæ specially in the "protaspis stage" not noticed hitherto—the most important being the appearance of eyes later than the facial suture, palpebral lobes and free cheeks on the dorsal side—instead of migrating from over the margin from the ventral side, as formerly suggested. This "spontaneous generation" of the eyes on the free cheeks seems to develop during some critical moult which takes place in some trilobites earlier than in others. Secondly, the migration of free cheeks from an early anterior position to a late lateral position indicates that during the protaspid stages the cephalon is of the proparial type, whereas it becomes opisthoparial in the meraspid and holaspid periods. These observations suggest that the appearance of eyes in a later stage was in the nature of an "adaptational control" as a result of the existence of both larvæ and adults under aphotic or nearly aphotic conditions.

Paleozoic Foraminifera, their Relationships to Modern Faunas and to their Environment.

OUR knowledge about paleozoic foraminifera was usually confined to the study of fusulinids. Improved technique and intensive collection in recent times have revealed a large foraminiferal fauna throughout the paleozoic. The development of the group indicates that the earliest types had chitinous tests. During the next stage there was attachment of various foreign particles to the chitinous test. The upper cambrian form—Spirillina—indicates that the earliest foraminifera were tubular and consisted of an early proloculum. Later on the foraminifera developed an elongate undivided chamber often coiled about itself in one plane. Foraminifera with calcareous tests have not been reported till carboniferous times and this suggests that the primitive forms were predominantly arenaceous. At present the arenaceous forms occur in various habitats but most commonly in waters of

medium depth in temperate regions. In waters where calcareous materials are abundant, the chitinous cement which would hold the foreign particles on the test would be converted to calcareous substance thus giving rise to calcareous tests. From these observations J. A. Cushman (*Jour. of Palæo.*, **9**, No. 3) suggests that calcareous foraminifera developed later and had a limited habitat.

C. P. K.

The Yeravas of Coorg.

By Rao Bahadur L. K. Ananta Krishna Iyer.

Introduction.—The *Yeravas* are the aborigines of Wynad, one of the taluks of South Malabar, from which they gradually spread to the forests of South Coorg. They are rarely found in the northern division. They are the lowest of the jungle tribes of Coorg. They appear to have been, from a remote period, in a servile relation to the *Betta* Kurumbas. They are now scattered all over the villages of the two *Nads* of Ponnampet and Srimangala.

Internal Structure of the Tribe and Habitat.—There are four endogamous groups, *viz.*, the *Panjiri*, the *Pania*, the *Badava*, and the *Kagi* Yeravas or *Karatte*. The *Panjiri* stand highest in the social scale, and the *Kagi*, the lowest, because of their habit of eating crows (*Kan Kagi*). The *Panjiri* Yeravas are divided into two sub-groups, *viz.*, *Ippumale* Yeravas and *Karatti* Yeravas. The former are said to have immigrated from *Ippumale*, which is situated beyond the Manantoddi river; and are generally found in Srimangala and Ponnampet Nads; and the latter in *Karattimale*, near Bythor. Though they belong to one and the same group, yet there is no intermarriage between them. *Panjiri* Yeravas have come from Mysore. The *Badava* Yeravas who are mostly found in Mysore near Heggadadevanakote, are rarely met with in Coorg. There is no interdining and intermarriage between these two classes. There is also not much difference between the *Pania* and *Karatti* on the one side, *Panjiri* and *Badava* on the other. The *Panias* and *Panjiries* neither interdine nor intermarry. A *Panjiri* can become a *Pania* but not *vice versa*.

Habitations.—The Yeravas live in thatched huts. The walls are made of bamboo reapers, interwoven and plastered with mud. They never build a house with mud walls because of their migratory habits. Frequently they run away without provocation from their old masters to some distant places in the forest and on settling down under another landlord, they proceed to build a fresh hut. Their dwelling places generally have a veranda of about 10 feet square. Walls are half built all round. Their fire-place is on one side. They have a small pit to pound paddy in. Their domestic vessels are mostly earthen pots and dishes. The latter are used for taking food. They rarely use copper or brass vessels. Before the occupation of a newly built house, the Yerava worships *Kuttathamma*, their chief deity and *Gulikan* (a demon) with offerings of rice, cocoanut, toddy, banana and fowl, with the prayer, "O! Ye Divine Beings, by your grace we have built this hut; keep watch and ward over us and our family."

Betrothal.—Cross-cousin marriage is in vogue amongst them. The Yeravas avoid all relations on the father and the mother's side. The Yerava adults have no voice in the choice of a maid for wife. It is generally their parents who negotiate for the marriage of their sons. When a young man has reached the marriageable age, and a suitable girl is found, his parents and the headman of the tribe* (*Kanalādi*) take the *tāli* or marriage badge, a *sādi*, and all the articles necessary for their food to the hut of the bride-elect. They prepare the food, light an oil lamp filled with cocoanut oil and offer sacrifice to their gods, *Kuttathamma* and *Gulikan* along with cocoanut and banana. Some rice also is placed in a sieve. The maid's *Kanalādi* asks them the object of their visit. The young man's *Kanalādi* replies that they have come to propose the marriage of their daughter to the young man. The girl and the young man's names are also given. Then, the bride's *Kanalādi* says in the presence of the gods and those assembled, that they are prepared to give the maid in marriage to the young man. She is brought to the presence of the parties assembled. They then pray to their gods to help them in the celebration of the marriage. The *Kanalādi* of the bridegroom-elect ties the *tāli* round the girl's neck, and gives the *sādi* to her with one *hana* (three annas). The parties sit together and partake of the food already cooked. The maid's *Kanalādi* fixes the date of marriage (*Mangala Kurippu*). Generally the betrothal takes place a month before the marriage, to the celebration of which the *Kanalādis* on both sides must consent. If the bride's party cancels the betrothal, they have to pay the expenditure incurred by the parents of the bridegroom-elect. If the fault is due to the indifference or neglect of the bridegroom's party they should forfeit everything given to the bride-elect.

Marriage Ceremonies.—On an auspicious day before the celebration of the marriage, the relatives of the bride and bridegroom assemble in the respective families. *Chapras* are erected with ten or twelve poles in front of the houses of both the bride and bridegroom. Pigs or fowls are slaughtered. Ancestors are worshipped. Parties assembled are treated to a feast. The night is spent merrily by the beat of drum and the tuning of pipes for dancing. On the day of marriage the young man is bathed, neatly dressed and adorned, and is conducted to the marriage in procession. He is seated on a tripod a foot high. A lamp is lit before him. His mother and other married women throw rice on him as a token of blessings, and give him a present of a few

---

*The name *Kanalādi* in Wynad and Coorg is applied to a class of men who act as "Oracles", "Fire-walkers" and "Devil-dancers".

annas. Then follow others, after which the members assembled there are sumptuously entertained. In the evening the bridegroom's party start in procession to the family of the bride-elect so as to reach it before day-break. They halt near the residence of the bride-elect. The bride's party welcome them with light refreshments and toddy. They are conducted to the marriage booth in front of the hut of the bride-elect. As the bridegroom-elect enters the booth, an elderly woman of the family washes his feet, for which one hana is paid to her service. He is then seated on a tripod. All the gods of both parties are served with parched rice, cocoanut and bananas. The bride and bridegroom are asked to stand together, and the gods are invoked to witness the ceremony and to bless them when the assembled guests throw rice and give them presents, varying from three pies to three annas. The *Kanalādi* asks the bridegroom to grasp the hand of the bride. The guests assembled there are treated to a feast, after which the bridegroom and his party with the bride return to his hut. Just then the bride's mother or some elderly woman stands at the gate, when the bridegroom gives her eight annas and requests her permission to take the girl. In the family of the bridegroom the same formalities are gone through. The bride touches the feet of everybody as a sign of obedience and respect to the elderly members who give some presents of coins which become her pocket-money. The *Kanalādi* comes on the fourth day. The bride is bathed, dressed and adorned in her best. She performs the *Gangapuja* and brings water to the hut in a few pots. She is then dressed in a new *sādi*. After a sumptuous meal the guests disperse. There is no special ceremony for consummation which takes place in the bridegroom's hut after his return with the bride. The married couple again go to the bride's family, stay there for a few days and then with the bride return home. Thereafter they live as husband and wife.

If the parents are unable to meet the expense of the ceremony, they connive at the young persons making friends, and the girl one day elopes with the young man, and remains in the forest for a few days, and then the girl returns to her hut. She is not allowed to enter it. Her parents inform the villagers who assemble to enquire into the matter. The *Kanalādi* comes. The couple confess their guilt, and pay a fine of a rupee or two, when they are condoned. The *tāli*-tying takes place. They become husband and wife. These formalities cost five rupees, while the marriage ceremony requires twenty-five rupees. A man can have more than one wife. The first wife has no special privileges. Concubinage is also allowed. Widow marriage is in vogue amongst them. On the day fixed for the marriage ceremony the man goes to her hut with his friends and relatives, invokes his gods for blessings, and ties a *tāli* round her neck, and gives her three annas. Thereafter they become husband and wife.

Adultery and Divorce.—Adultery and divorce are current among them. When a woman commits adultery with a man, and when that is known, a meeting of the tribesmen is called for to enquire into the matter. When it is proved the delinquent has to pay a fine of one to ten rupees. Sometimes he is compelled to marry her after payment of the marriage expenses for which he is responsible. A man can divorce his wife at his will and pleasure, when he simply takes her to her parents and says that he does not want her. This is the ordinary form of procedure. Sometimes the husband in a fit of provocation sends her out of the house, saying that he does not want her, and that she can go where she likes.

Pregnancy.—When a woman is pregnant her parents visit her during the seventh month, give her sweets and stay with her for a day or two, and then take her to their hut.

Delivery and Child-birth.—The Yeravas put up a temporary hut for the delivery and confinement of their women. When a woman suffers from pains of child-birth an elderly woman of the family—usually her mother—acts as her nurse. Soon after delivery, the mother and the baby are bathed in warm water, and this is continued during the period of uncleanliness. Soon after delivery, she is given a decoction of cumin seeds, ginger, asafœtida, and fed with rice *kanji*. The pollution is for eleven days and she bathes on the twelfth, when the naming, feeding, and cradling formalities are gone through. She continues to be in a state of uncleanliness for a period of forty days.

Family.—Family is patriarchal. In the absence of children to a man, he can adopt a boy, below twelve years of age. The *Kanalādi* comes and the boy is bathed and dressed in new clothes. Their gods are worshipped with offerings of rice puddings, cocoanuts and bananas. The *Kanalādi* holds the boy's hands and says that henceforth he is the son of so and so; "let the gods who are invoked bear witness". He hands over the boy to the person who adopts.

Every adult member of the family should work and earn his daily bread, unless he or she is sick, old and infirm. Not even one per cent. of the Yerava population owns lands. They are all coolies. An Yerava will preserve nothing for the morrow. He wants everything fresh. The family—both husband and wife—goes to work, and each member gets food and paddy as wages. They bring the paddy, and the woman pounds only as much of the paddy as the family requires for the night's consumption. The man will sit near the fire or in the moonlight during the dry weather beating his drum and singing. The boys and girls dance, sometimes the woman also joins the dancing party. At the time of the harvest and on full moon days the drumming and dancing will last throughout the night. They never use a lamp in their huts. Often a Yerava feels reluctant to work. He does not care for the urgency of his master. He will quietly walk with his wife into the jungles in search of honey, fruits, roots or fish. Generally the wife cooks the food. But there is no objection if the husband joins her.

Tribal Organisation.—The villagers assemble together at a certain place once in a year, the main object of which is to offer prayers with sacrifice to the spirit of the dead. The meeting continues for three days. Every family has to bring rice, cocoanut, toddy, etc. First they enquire into and discuss about cases of adultery, divorce, elopement, etc., if any. The *Kanalādi* presides and decides such cases. Then the deities and the names of the dead are propitiated with rice

puddings, cocoanut, toddy and fowl. The *Kanalādi* performs the rites, sings songs in praise of the sanity and powers of the tribal deities *Kuttathamma*, *Gulikan*, *Kuttichathan*, and the dead heroes who have done great deeds such as killing tiger, driving away demons and other spirits. When this is over they eat and make merry. The Yeravas have their own pipes and drums, and bring as many sets as they can afford. Young men, women and children join together and dance in a circle to the piping and beating of drums. This continues day and night. It is chiefly in this "*Pandalata*" that women (other's wives) and grown-up girls are enticed away by men. They quietly slip away at night and seek their abodes in the forest for some days or go away to distant villages where they live as man and wife. Those who escape into the forest return in a day or two. The *Kanalādi* fines them, compensates the husband of the woman by payment of a few rupees. If the fine is not paid, the culprits will be expelled. Nobody dares to go against the judgment of the *Kanalādi*. His post is hereditary.

Sorcery and Witchcraft.—They believe in magic, sorcery and witchcraft like the jungle tribes. Spirits and Gods are believed to enter into the body of *Kanalādi* or some other person appointed by him. The spirit or the God will speak through the man, give information of the past and prophesy. They believe in the potency of evil eye. All kinds of disease are brought about by the evil spirits or demons, and the gods of the *Panchamas* to obviate which talismans, enchanted threads and certain beads are worn by them.

They practise sorcery. The sorcerer draws the picture of a demon with rice powder and to make it appear fearful to look at, he puts powders, coloured red and black, here and there, and keeps cocoanut oil lamps. Bamboo sticks about a cubit long are sharpened at one end pointed like a pencil. Clean cloth is tied at one end, and then it is dipped in the oil and lit. This is the lamp used on such occasions. Beaten rice, etc., on plantain leaves is kept at one side. The sick man is made to sit before the leaves. The sorcerer with coloured water in his hand begins to utter his incantations and finally kills a fowl, after sprinkling the water on it.

In case of exorcism by dance the sick man is made to sit in the centre, and is decorated with flowers and *kunkum*. The sorcerer and his subordinates beat their drums and dance round the man singing peculiar songs. Sometimes the sick man if he is believed to have been possessed by a spirit, is beaten with a cane. He then runs; the sorcerer takes him to a tank or river and makes him dive and come out. He (sorcerer) gives him new clothes to wear. The spirit is then supposed to have left him by this time.

Religion.—Their gods are *Kuttathamma* and *Kali* who are believed to reside in a place near Kutta, a small town between Coorg and Malabar. *Chāmundi* and *Kāveri Amma* are their chief deities.

The routine form of worship is as follows.—The *Kanalādi* keeps rice, cocoanut, etc., in a neat place, lights a cocoanut or a castor oil lamp and stands before it, facing the sun, and prays to God, requesting Him to grant what the worshippers want. They keep no image, but plant a rough stone under a tree to represent their *Gulikan*. At Kutta their chief Goddess *Karingali* or *Kuttathamma* is represented by a stone. They offer toddy, a fowl or two with prayers when they worship. They worship *Ganga* (water goddess) during marriage ceremonies. They observe all the Coorg festivals and those of the high class Hindus, namely,

1. *Makara Sankramana* in January.
2. *Sivaratri* in February.
3. *Gowri* and *Ganesa* in September.
4. *Kalimuhurta* in September (Coorg festival).
5. *Kaveri Sankramana* in October.
6. *Hutri* in November or December.

The Yeravas have a *Karingali* mutt in Wynad. Some go there as pilgrims. They fast during *Kuttathamma* festival in February. This festival lasts for seven days. They do not worship rocks or trees, but plant rough stones under a tree to represent their gods and demons.

The fields are believed to be haunted by devils, for which they offer sacrifice. The *Kanalādi* comes to Kutta during the *Karingali* festival. He is the final authority on all religious disputes and on matters connected therewith.

The Yeravas worship the Mother Earth, the river Cauvery, *Lakshmanathirtha* and other springs. Before commencing to dig a well they consult their priest and sometimes they sacrifice fowls and offer cocoanuts.

Funeral Customs.—The dead are generally buried. The dead body is washed and covered with a new white cloth. It is then covered with earth. Some rice and milk or if milk is not available, cocoanut water are poured into the pit. Some rice and water are also placed close by. On the eighth or tenth day the funeral ceremony is performed. They call it *Kake Pile* (bali) and keep food for the crows. The hut is smeared with cow dung. All bathe. The *Karanavans*—all the dead—are offered food, meat and toddy. The *Kanalādi* calls upon the God and the Sun to give a good place to the spirit of the dead, and protect the living members of the family. The closest relations keep the offerings outside the hut for the departed soul. If crows do not eat it at once, the members of the family think that there has been something wrong, and also infer that gods and the departed souls are angry with them. Often they perform the ceremony again on another day.

Occupation.—The chief occupation of the Yeravas is agriculture. They have no lands of their own, but work for wages. They select auspicious days for ploughing, sowing seeds, transplanting and reaping. They also know which rain is the best one for each crop, and some foretell by the commencement of the rain, the year's crop. They perform no ceremonies either at the beginning or at the end of the agricultural operations. But like other agricultural communities they worship the implements, bullocks and the like.

Prædial Slavery.—Prædial slavery in Coorg differed only in a few respects from that in the districts below the ghats. The members here were condemned to this state of servitude and were in a complete state of degradation. They belonged to three classes, one below the other; and all belonged to the lowest grade of society. Three to five members were owned by a proprietor of a small estate. Though they were not treated with severity, the general conditions of their

service subjected them to great hardships. They were rarely sold, but were frequently given as security for the money borrowed. This was the most general mode of transferring the usufruct, and one, above all others, likely to produce the greatest wretchedness. The mortgagee had the benefit of their services for the time being, and this was considered as equivalent to the interest for the sum advanced. They are now free. The state of prædial slavery here described is to some extent similar to that of the rural vassalage yet known in Poland and parts of Russia.

The prædial servants of the agriculturists were obliged to perform the work of the Circar. The servants of every ryot were at the disposal of the Circar, and their service given as a matter of right which was generally admitted. Each cultivator had to supply a certain number in proportion to his means, and the *Parputty* of the *Nad* was entrusted with all arrangements regarding them. Each Nad had to furnish a certain number of labourers for work. This requisition extended also to the Nads below the ghats. The body of labourers thus always collected was generally employed at the Capital, (Mercara), where works of some kind or other were constantly undertaken. No compensation was given to the owners of the servants thus employed ; because it was termed *Kwhee* or voluntary, and consequently the servants got no wages. They were fed by the Circar during the period of work. This system pressed hard on both masters and servants, particularly the latter, who felt and considered it a serious evil. There were numerous other instances in which labour was supplied to the Government without any remuneration.

Social Status.—The Yeravas avoid the food cooked or touched by the Muhammadans, Panchamas and others who eat beef. They eat food cooked by the members of the other castes.

Appearance, Dress and Ornaments.—The Yeravas are diminutive in stature. Their complexion is dark, and their whole appearance carries with it an air of wretchedness. Their garments consist of a loin cloth, and they wear no head gear. The hair is tied into a knot on the top of the head, which gives them a wild and savage aspect. Those who have observed them confirm that they possess the Negroid characteristics with thick lips and compressed nose, though both features have been considerably effaced. Their curly hair is very much softened by combing.

Conclusion.—The Yeravas have very much improved of late. Both men and women are hard working, and they are therefore in great demand in coffee estates. They are not reliable, and the contact with estate coolies and maistries has spoilt their simple habits and made them adepts in cunning and cheating. They often decamp from their bamboo huts in the jungle, and travel with kin unobserved in one night out of reach of the pursuer. They often run away with advances, and extend their wanderings to Wynad, and on their return they easily find new masters with little or no chance of discovery especially when employed in Coorg houses during the working season. They conform as much as practicable to the mode of life and worship of the Coorgs. Like the Kurumbas they are chiefly found in Kiggatnad and Yedalknad taluks.

Science Notes.

Some Observations on the Thermal Structure of Cumuliform Cloud:—R. G. Veryard (Indian Meteorological Department, Scientific Notes, Vol. VI, No. 61).—During 1932 and 1933, a number of observations were made at Peshawar, Kohat and Risalpur, in the N. W. F. P., of the temperatures (dry and wet bulb) inside and outside cumulus and cumuliform clouds. Although the readings cannot be accepted as reliable to within less than 1°F., they are interesting inasmuch as they confirm that the temperature inside cumuliform cloud may be higher or lower than the temperature of the surrounding air. An analysis of the results shows that (*a*) on thirteen out of the fourteen occasions when the cloud was observed to be dissolving, its temperature was mainly lower than that of the surrounding air, and (*b*) out of twenty occasions when the cloud was observed to be growing, its temperature was mainly higher than that of the surrounding air on ten occasions but mainly lower on six occasions. With regard to the question of supersaturation, the observations do not show convincingly that supersaturation occurs in cumuliform cloud.

* * *

The Geological, Mining and Metallurgical Society of India.—At the 10th annual meeting held in August, the following were elected members of the Council for 1935-36:—

President: Prof. N. P. Gandhi. *Vice-Presidents*: Mr. P. Evans and Mr. J. K. Dholakia. *Joint Secretaries*: Mr. N. N. Chatterjee and Prof. S. K. Bose. *Treasurer*: Mr. S. L. Biswas. *Librarian*: Mr. B. N. Maitra. *Other Members of the Council*: Prof. M. Chatterjee, Dr. P. K. Ghosh, Mr. H. M. Lahiri, Mr. D. C. Nag, Mr. G. G. Narke, Mr. B. Rama Rao, Prof. S. K. Roy, and Mr. K. K. Sen Gupta.

In the course of his Presidential address, Mr. M. M. Mukherji dealt with the *Present Day Problem of the Indian Coal Industry.* The principal mining industry of India, *viz.*, the coal industry, is now practically on the verge of collapse. This is partly due to the economic depression and partly due to the very wide margin that exists between demand and the immediately available productive capacity. The latter is really more serious because the surplus productive capacity of the mines induces the owners to sell their coal at any price, which ultimately proves detrimental to the producers as a class.

The question is how to rescue this industry from the quagmire of depression ? The one immediate remedy suggested is the closing down of the Railway Collieries. Out of the total consumption, the Railways account for over ·34 per cent. Although it is true that at present the Railway collieries supply only a part of this, they possess potential possibilities for supplying the whole of the Railway requirements. Their closure will automatically restrict the output and cannot

fail to have a salutary effect on the industry. The Railway Authorities contend that the closure of the collieries would mean a recurring expenditure of 41 lakhs of rupees a year for maintaining them in good working condition. Mr. Mukherji suggests that the coal trade will not probably be unwilling to pay this amount, if Government would collect that sum by levying some cess on coal despatched as long as Government is not in a position to sell those collieries at a fair price.

Mr. Mukherji also dealt with the problem of metallurgical coke. This particularly valuable class of coal far from being conserved for use in industries, for which they are eminently suited, is being used for purposes where inferior grades would suffice. It has been estimated that for the years 1931 and 1932, of the total amount of coal mined in India suitable for the manufacture of metallurgical coke, only 13.9 and 14.7 per cent. respectively was used for the manufacture of hard coke. The Coal Fields Committee reported "that the Railways should be recommended to use more of inferior coals for shunting purposes in marshalling yards and that mills and other industrial consumers might also adjust a type of furnace specially designed for burning low grade fuel." The problem of conservation of metallurgical coal is of vital interest to the growth of the metallurgical industry in India.

The embargo placed on the export of coal in 1920, resulted in the "disappearance of Indian Coal for overseas market for the time being" and to recapture a lost market, strenuous efforts and Government's active assistance are needed. It is mentioned that India obtained in 1920 one and half crores of rupees by exporting coal, while in 1933, she realised only 41 lakhs through her exports.

* * *

International Commission of Agriculture.—The Commission held its general assembly at Brussels and Gumbloux (Belgium) under the chairmanship of the Marquis de Vogue (France), President. The assembly devoted special attention to the present condition of Agriculture, which appears to have grown worse in spite of the useful measures taken in certain countries. The two main problems which require solution are (1) the wheat problem, and (2) the edible fat problem. According to a report in *Nature*, the Commission resolved to hold its next meeting in 1936, in Oslo, and the twelfth International Congress will take place at The Hague in 1937.

* * *

Empire Meteorologists' Conference.—The third Conference of the Empire Meteorologists was held at South Kensington on August 12–21. The meetings provided an opportunity for Directors of Services to exchange views on diverse subjects. Considerable attention was devoted to meteorological arrangements necessary to meet the Government's requirements in connection with the Empire Air-Mail Service. A few problems arising in this connection are the making of synoptic charts on a uniform plan and the coding of reports from land stations and air-ships. Other subjects discussed concern meteorology for the Army and for the Navy, instruments, upper air observatories, marine meteorology, geophysics, climatology and agriculture and seasonal forecasting. In connection with geophysics, the Conference passed a resolution recommending the establishment of a station at Chesterfield Inlet, Hudson's Bay, Canada. This station would be in near proximity to the North Magnetic Pole and its situation would also be very favourable to auroral studies. The Conference also recommended the establishment of a station at Tristan la Cunha, observations from which, situated as it is, about midway between the Cape of Good Hope and South America, would be of great value. Regarding climatology and agriculture it was suggested that climatological data should be broadcasted. The outline of a scheme was proposed for broadcasting of brief data from related stations in each country on the fifteenth of the month following that to which the data refer.

Twenty-five dominions and colonies were represented at the Conference.—(From *Nature*, September 7, 1935).

* * *

The International Faculty of Science (Central Office: 85, Gloucester Place, London).—At the meeting of the Council and Executive Committee held on Wednesday last (September 4th, 1935), a resolution was unanimously carried "that Professor M. Sayeed-ud-Din be appointed a Vice-President of the Faculty for India, in the place of Professor Hunter, resigned".

* * *

Dr. Friedrich Levi has been appointed Hardinge Professor of Higher Mathematics, in the University of Calcutta. Dr. Levi was formerly extraordinary Professor of Mathematics at the University of Leipzig. The appointment is made for a period of five years.

* * *

Sir Josiah Stamp, statistician and reputed economist, Chairman of the London Midland and Scottish Railway, has been elected President of the British Association for the Advancement of Science, 1936.

The British Association will meet at Blackpool next year from September 9 to 16, and will visit Nottingham in 1937, Cambridge in 1938, and Dundee in 1939. The 1940 meeting will be in Australia.

It is suggested that a select party of the British Association be sent in winter of 1937–38 to take part in the Jubilee Meeting of the Indian Science Congress.

* * *

Mr. R. M. Statham has handed over charge to Sir George Anderson, as Education Commissioner to the Government of India.

* * *

Sir Richard Paget, Bart., recently announced at the International Congress of Phonetic Sciences that the most universal language is that of signs. Sir Richard has been comparing the sign-languages all over the world and he is of opinion that the sign-language is so fundamental and natural that uneducated deaf mutes from the Far East or African jungles can talk with English deaf mutes and make themselves understood.

* * *

Col. Gill, the Malaria Expert, who was specially appointed by the Government of Ceylon to investigate the causes of the epidemic in November last, has recently submitted his report to the Executive Committee of Health. The epidemic of 1934–35 which overtook that Island was of exceptional magnitude, and it is predicted that

for some decades to come an epidemic of that intensity will not occur. Another epidemic is however predicted in 1940. The last sweep accounted for over 38,000 deaths in three months, and forty lakhs of rupees have already been spent by the Government for relief measures, and a sum of fifteen lakhs of rupees has been provided in the new budget. It is understood that Col. Gill recommended the enactment of an anti-mosquito ordinance to arm Government and local authorities with powers to insist on tenants of houses and estate owners to carry out all reasonable anti-malarial measures. No special organisation for controlling malaria is called for, and the local malarial organisation should be sufficient to deal with the control measures.

* * *

Fridera.—The causes leading to the premature failure of wooden sleepers in railways, is due to (1) mechanical abrasion, and (2) natural decay. The former is accentuated by the looseness of rail fastenings; this is otherwise called 'Spike-killing'. The chemical destruction of wood fibres at the rail seat also adds to the failure of wooden sleepers, thus rendering them unsuitable, long before they become useless through natural decay. At the request of the Railway Board, the Chemical Branch of the Forest Research Institute, Dehra Dun, undertook to evolve a composition which could be melted and poured into the worn-out spike holes, and the spikes then fixed into position; when cold the composition would set hard and have a firm grip both on the wood and the rail. The manipulation should be made *fool-proof* and the composition should have a sufficiently high fusion point to withstand the summer heat of India (temperatures up to 150° F.). A composition has been evolved and patented by Dr. S. Krishna under the name of *Fridera.* The holding power of the composition is excellent, requiring a load of 6,000–7,000 lbs. to pull out the spike, the untreated wood requiring 3,000–4,000 lbs. only. Trials have been made upon tracks and proved satisfactory. Tests conducted by Mr. V. D. Limaye at the Forest Products Laboratories, Canada, have shown that *Fridera* does not lose its grip at low temperatures, as low as −20° F. It has thus been demonstrated that *Fridera* retains firm grip both on metal and on wood under extreme variations of temperature.

The Forest Research Institute has also been responsible for developing and patenting an efficient wood preservative under the name *Ascu* (Patented by Mr. S. Kamesam) which increases the durability and life of wood, and makes possible the utilisation of sap woods and jungle woods for construction purposes (see *Curr. Sci.*, 1935, **4**, 89). It is thus possible to reduce considerably the heavy expenditure incurred in renewal of sleepers by (1) minimising mechanical abrasion by the use of *Fridera*, and (2) by prolonging the life of the wood by treatment with *Ascu.* (Extract from *Indian Forester*, 1935, **61**, 660.)

* * *

In an interesting note published in *Nature* (September 7, 1935) Mrs. Barlow has, as a result of her examination of the unpublished Darwin manuscripts, brought out evidence to show that as early as September 1835 Darwin began to question the stability of species. It is generally held that during the weeks spent at the Galpagos Islands, Darwin first considered the possibility of the transmutation of species. The question, at what period during the *Beagle* voyage did his views crystallise?, appears to have been answered by the occurrence of a significant passage "for such facts would undermine the stability of species." in Darwin's unpublished manuscripts dealing with the fauna of Galpagos Islands.

Royal Institute of Science, Bombay.—Dr. T. S. Wheeler, Principal of the Institute, has been re-elected Dean of the Faculty of Sciences of the Bombay University for the next academic year.

Prof. P. R. Awati of this Institute and Dr. Venkatraman of the University Technology Institute have been appointed local Secretaries of the Second Meeting of the Indian Academy of Sciences, to be held next December in Bombay.

* * *

The Journal of the Indian Mathematical Society (New Series, Vol. 1, *No.* 6).—The conception of the line of striction of a singly infinite family of curves on a surface is due to C. E. Weatherburn (*vide Math. Gazette, Vol.* 13). Mr. V. Rangachariar (Patna) in a paper in the present issue of the *Journal* examines under what circumstances the line of striction of a system of asymptotic lines of a minimal surface can be a trajectory of the system.

Dr. R. Vaidyanathaswamy, M.A., D.SC., presents a paper on the Extension of the Determinant Concept, wherein by using methods based on Group-Theory, he improves upon a previous publication of his, entitled "On Mixed Determinants."—(*Proc. Roy. Soc. Edinburgh*, 1925.)

R. Vaidyanathaswamy and B. Ramamurti have a note on the "Rational Norm Curve", wherein they make a further study of a correspondence between quadric envelopes in S_n and linear line complexes in S_{n+1} studied by R. Vaidyanathaswamy elsewhere.—(*Jour. Lond. Math. Soc.*, 1932.)

Journal of the Bombay Natural History Society.—We have received Vol. **38**, No. 1, of the *Journal of the Bombay Natural History Society, Bombay*, and we note that it abounds in articles relating to faunistic and floristic natural history. There is a most thrilling article on Rhinoceros Shooting in Burma and it makes very interesting reading particularly after following Mr. Morris's account of the hunt for a rare species of Rhinoceros needed for the American Museum of Natural History. Mr. W. S. Thom, the author of the article in the journal, tells us that specimens of *R. sumatrensis* are very common

while the single-horned *R. sondaicus* is not at all met with though it is said to exist in Burma. There are other articles on Game birds, Game sanctuary, Ornithology of Travancore and Cochin, Caddis-flies, Flora of Bombay Presidency, Papaw tree, Beautiful Indian trees, Medicinal and poisonous sedges of India and others. Besides reviewing some important books, a large number of pages is devoted to miscellaneous notes and no less than 43 short articles of natural history interest are published under this head.

Announcement.—

Indian Central Cotton Committee.—Facilities for Training at the Technological Laboratory, Matunga, Bombay.—As in the past the Technological Laboratory will admit this year two students for training in the elements of spinning and the routine methods of testing cotton fibre and yarn. The selected candidates will be expected to join on the 2nd December 1935 and will conform to the Laboratory regulations regarding hours of work, etc. The course will normally last for a period of six months and a fee of Rs. 50 only will be charged for the full course.

Candidates desirous of admission should submit written applications to the Director, Technological Laboratory, Matunga, Bombay, so as to reach him not later than the 1st November 1935.

International Geological Congress.—Seventeenth Session, USSR, 1937.

In view of the fact that the twentieth anniversary of the existence of the Soviet Power will be celebrated in 1937, the Government of USSR has decided to summon the Seventeenth International Geological Congress that year.

The session will open in the beginning of August and July will be devoted to excursions before the Congress, and the second half of August and September for excursions after the Congress. The Organisation Committee has proposed the following topics for discussion at the session:—

(1) Problem of Petroleum and Petroleum Resources of the World.
(2) Geology of Coal Fields.
(3) Pre-Cambrian and Mineral Deposits in Regions of its Expansion.
(4) Permian System and its Stratigraphical Position.
(5) Correlation of Tectonic Processes, Magmatic Formations and Ore Deposits.
(6) Tectonic and Geochemical Problems of Asia.
(7) Deposits of Rare Elements.
(8) Geophysical Methods in Geology.
(9) History of Geological Knowledge.

The Committee welcomes suggestions regarding further topics suitable for discussion.

Five excursions taking 15–28 days have been planned before the session ; and four large excursions covering very wide regions and taking 40–50 days, after the session.

Those who wish to offer suggestions to the Organisation Committee concerning the Seventeenth International Geological Congress, are invited to communicate with the Committee, Moscow 4, Kotelnicheskaya Naberezhnaya, 17. Telegraphic Address : Moscow, Geocongress.

National Institute of Sciences of India:

August 24th, 1935. The following papers were read and discussed:—

(1) R. N. CHOPRA, S. N. MUKHERJEE AND K. V. KRISHNAN: *A Note on the Role of Electrical Charge in the Phagocytosis of Red Cells in Malaria.*—It is now an accepted fact that the immunity as observed in malaria is the outcome of the phagocytic activity of leucocytes. The idea regarding this activation on the part of the phagocytes still centres round the formation of a specific antibody in the system as in bacterial infections, although the existence of such an antibody could not be definitely established by different workers; (Thomson, J. G., *Brit. Med. Jour.*, 1918, **2**, 628; Kingsbury, A. N., *Trans. Roy. Soc. Trop. Med. Hyg.*, 1927, **20**, 359; Manson Bahr, P., *Trans. Roy. Soc. Trop. Med. Hyg.*, 1927, **21**, 63, etc.). Brown (*Brit. Jour. Exper. Path.*, 1933, **14**, 413) from an analogy of the changes in the proteins of the serum and in the electrical charge of red cells indirectly indicated the probability of the existence of an antibody which, by reducing the electrical charge on red cells, was instrumental in bringing about ingestion by leucocytes, though he admitted that the action of serum in such cases was not specific. The work of Chopra and Chaudhury (*Ind. Jour. Med. Res.*, 1933, **21**, 273) showed however that the electrical charge of red cells in human malaria did not always show a reduction, but on the contrary a marked increase in many cases. Hence the immunochemical explanation of the increased phagocytosis in malaria did not seem to be adequate specially in view of some definite biochemical alterations observed in the blood.

The present work was done on *Silenus rhesus* monkeys with a heavy infection (nearly 70% of the red cells) of *Plasmodium knowlesi.* Migration velocity in an electric field of infected and uninfected red cells were determined in the different stages of parasites' growth. The migration velocity of the reticulocytes, popularly believed to be free from protozoal attack, was also determined. The first point observed was an inequality of speed between infected and uninfected cells that was manifested by the overtaking of one cell by another. Infected cells, in general, were found to be slower. This was contrary to all experience in the case of normal cells. Secondly, a study of the variation of migration velocity in different stages of parasites' growth revealed an increase of migration velocity in the ring stage and a marked decrease in the fully mature schizont stage as compared to normal cells. The healthy cells in these infected specimens all along showed a slight increase. An inference was arrived at from these observations that towards the end of schizogony when the mobility was comparatively lower, the phagocytosis of such infected cells should be more prominent. The equality of the migration velocities of reticulocytes and adult red cells pointed to the possibility that reticulocytes should be equally liable to be infected with parasites as adult red cells are found to be. Infected reticulocytes were actually detected in one case and the relative freedom of these from infection was explained as not due to any peculiarity on the part of such cells but probably to their insignificant numbers in the blood, owing to which, according to the calculus of probability, a small infection should be the result.

The relationship between the migration velocity and the electrical charge was discussed in the light of Lamb-Helmholtz equation: $U_0 = D.E/4\pi$. The relationship between electrical charge and phagocytosis was again given by the term $e^{-q \cdot q'/D.d.k.T}$. U_0 represents migration velocity per unit time, per unit potential gradient; D, the dielectric constant of the medium; E, the potential of the Helmholtzian double layer: q, the charge on a red cell; q', the charge on an ingesting white cell; d, the distance between the centres of these two types of cells at the point of their nearest approach; k, the Boltzmann constant; T, the temperature in the absolute scale and e, the base of natural logarithms. This term was deduced from a consideration of the

electrical work necessary for the approach and collision between two similarly charged particles as in the case of colloid micelles. From this the inadequacy of the part played by the electrical charge of red cells alone in such phenomenon was clearly evident; the importance of the charge of white cells as well as of the dielectric constant of the medium was simultaneously brought out from a theoretical point of view. The changes in the cholesterol content of the plasma and its effect upon the phagocytosis of red blood-cells in a few cases justified our conclusions to a certain extent. The phagocytosis of the actual protozoa during their short extracellular existence was dealt with from the mathematical considerations of probability and finally the importance of the physical factors and of the biochemical alterations in the plasma were also brought out from a theoretical point of view.

(2) W. D. West: Nappe *Structure in the Archæan Rocks of the Central Provinces.*—Evidence is brought forward to show that around Deolapar, in the Ramte tahsil of the Nagpur district, there occurs a sharp discordance in the succession of the Sausar series, at which position one or more stages are missing. The trace of the discordance is an irregular closed line, and it is clearly not a simple thrust. The details of the structure suggest that there is a recumbent fold resting upon the surrounding rocks, from which it is separated by the discordance. Both the recumbent fold and the "slide" upon which it rests have been further folded into a syncline. A study of the lithology also supports this view of the structure, since the rocks forming the *nappe* are of a different facies from the rocks surrounding it. It is suggested that the two sets of rocks were far separated at the time of their deposition, and have since been brought into juxtaposition with one another by horizontal movement along the slide.

(3) Horace Barratt Dunnicliff and Jnanendra Nath Ray: *Loss of Morphine in Indian Opium on Storage.*—(*a*) Moist opium does not lose morphine on storage. (*b*) Opium dried at 60° C. stored in contact with air suffers a rapid loss of morphine. This is not completely prevented by storage in corked and paraffined bottles. (*c*) Opium dried at 98–100° and stored out of contact with air does not lose morphine to any appreciable extent. (*d*) There is no evidence of the formation of ammonium salts as a result of the oxidation. (*e*) An enzyme (peroxidase) has been isolated from Malwa opium which may be the factor responsible for the decomposition of morphine. (*f*) A fungoid growth noticeable on moist opium has been identified as that of *Scopulariopsis brevicavtis*, var. *glabra Thom.* (*g*) When this fungus is made to grow in a dilute solution of morphine hydrochloride in a suitable nutrient medium, a slight fall in the concentration of morphine is observed but the specific rotation of the solution does not change appreciably.

Indian Academy of Sciences:

September 1935. SECTION A.—R. Padmanabhan: *Fluorescence in Cyclohexane.*—With the help of a continuous distillation apparatus it is shown that pure cyclohexane has no fluorescence. K. L. Ramaswamy and G. Gundu Rao: *The Density and Compressibility of Silicane and Silicoethane.*—A convenient apparatus for their simultaneous measurement and the results obtained are given. R. S. Krishnan: *Molecular Clustering in Binary Liquid Mixtures (Variation with Composition and Temperature).*—A study of the intensity and depolarisation of the light scattered transversely by mixtures of phenol and water at different temperatures shows that formation of clusters and their size depend upon temperature and composition. M. A. Govinda Rau and S. Satyanarayana Rao: *On the Dipole Moment of Tetralin.*—The moment is only small of the order 0.4×10^{-18}, and not 1.66×10^{-18} as reported in the literature. B. V. Raghavendra Rao: *Doppler Effect in Light Scattering in Liquids. Part II.—Polarisation of the Transversely Scattered Radiations.*—With the typical liquids carbon tetrachloride, toluene and carbon disulphide, it is significant that besides the two Doppler components, the central component is also practically completely polarised. I. Chowla: *A Theorem on the Addition of Residue Classes: Application to the Number $\Gamma(k)$ in Waring's Problem.* V. N. Thatte: *Magnetic Double Refraction and Light Scattering in Fused Nitrates.*—The magnetic and optical anisotropies of the NO_3 group are the same as in nitric acid and crystalline nitrates. S. Ramachandra Rao: *Diamagnetism of Copper.*—On colloidalisation of copper, the diamagnetic susceptibility increases, the critical diameter below which large changes occur being $0.8\,\mu$. C. S. Venkateswaran: *The Raman Spectrum of Phosphorus.*—Yellow phosphorus as vapour, liquid, solid and solution in carbon disulphide has been studied. M. V. Nabar and T. S. Wheeler: *The Kinetics of Heterogeneous Organic Reactions: The Reaction between Benzyl Chloride and Solid Silver Nitrate.*—The reaction is independent of the amount of benzyl chloride but is proportional to the surface of silver nitrate present. C. S. Venkateswaran: *The Raman Spectra of Dioxane and Tetralin.* R. Ananthakrishnan: *The Raman Spectra of Heavy Water.*—The principal band is found to have a triple structure and two other new bands have also been observed. S. Bhagavantam: *Raman Spectrum of Deuterium: I.*—With deuterium at 17 atmospheres, five rotational lines and one vibrational line are recorded. The positions and intensities of these lines provide the first experimental confirmation of the theories regarding the D_2 molecule. S. Bhagavantam: *Raman Spectrum of Hydrogen Deuteride.* L. Sibaiya: *Hyperfine Structure in Selenium, Palladium and Gold.*—In Selenium and Palladium none of the levels examined reveals any even isotope displacement.

SECTION B.—T. N. S. Raghavachari and P. V. Seetharama Iyer: *The Use of Activated Carbon in the Purification of Water in the Tropics (The Madras City Water Supply).*—Activated granular carbon when used in a slow sand filter, as a sandwiched layer 1½″ thick, is effective in removing the colour, taste and odour. The organic matter is reduced; the carbon maintains its efficiency even after 2 years' continuous service. Charles S. Pichamuthu: *The Conglomerates and Grits of Kaldurga, Kadur District, Mysore.*—As the result of a detailed study of the pebbles and the matric, the writer has come to the conclusion that the conglomerates are not autoclastic as held hitherto, but that they are of a sedimentary origin.

M. J. PRESSWALLA AND C. J. GEORGE: *The Respiratory System and the Mode of Respiration of the Water-Bug*, Sphærodema rusticum *Fabr.*, *with Remarks on those of* Nepa, Laccotrephes *and* Ranatra.—The respiratory systems of the two forms of adult *Sphærodema rusticum* exhibiting peculiar alary dimorphism have been studied in detail. (MISS) KAMALA BHAGVAT AND MOTNAHALLI SREENIVASAYA: *A Dilatometric Method for Studying the "In Vitro" Digestibility of Milks.*—The dilatometric method affords an accurate and simple method for studying the digestions of milks. The behaviour of the casein particles in cow's milk towards tryptic digestion does not appear to be different from that of the casein particle in artificial solution. N. C. DATTA: *Investigations on Metallic Contamination of Foods. Part II.—Effect of Cooking and Storage of Food-stuffs in Aluminium Vessels.*—Feeding experiments with rats have shown that food prepared in aluminium vessels has no harmful effect on growth, reproduction and general well-being of the animals. H. B. SREERANGACHAR: *Dilatometric Studies in the Enzymic Hydrolysis of Polysaccharides. III.—Hydrolysis of Starch, Amylose and Amylopectin by Takadiastase.*—The depression per millimol release of maltose from potato starch, soluble starch (Lintner), amylose and amylopectin, are respectively 4.0, 4.0, 3.6 and 3·6 mm.^{3}. The depression per degree fall in rotation is 10.7 mm.^{3} in the case of both amylose and amylopectin.

Symposium:

October 5th and 6th, 1935. *Disease Resistance in Plants* (held at Coimbatore).

GENERAL.

(1) L. D. GALLOWAY (Pusa): *The Control of Fungal Parasites by the Plant.*—The control of harmful fungi can be considered under (*a*) infection, (*b*) humidity, (*c*) nutrition, (*d*) temperature, and (*e*) atmosphere. Infection may be seed, soil or air-borne and disease may be avoided by minimising chances of infection. In the study of the onset and progress of diseases humidity is an important factor but very little work appears to have been done. The problem of specificity of certain pathogenic fungi and the cosmopolitan nature of others has not been satisfactorily solved. The role of soil nutrient and the action of poisons and toxins on plants has to be clearly investigated. The growth of the parasites and the resistance of the host are controlled by temperature and the aid of certain chemicals like CO_2, NH_3, $CH_3 . CHO$, which have an inhibitory effect on the growth of fungi can be invoked for controlling several fungus diseases. The mechanism of disease resistance presents fresh series of problems for each host plant and each parasite and no general formula is to be anticipated.

DISEASES OF THE PULSE CROPS.

F. J. F. SHAW (Pusa): *The Inheritance of Morphological Characters and of Wilt Resistance in Rahar* (Cajanus indicus).—From a study of the F_1, F_2 and F_3 generations of a cross between a resistant and susceptible varieties of *Cajanus indicus*, evolved at Pusa, it has been shown that the resistance to wilt is conditioned by the presence of the complimentary character. Morphological characters like flower colour, erect or spreading habit of growth, tall or short structure of plant, crowded or open inflorescence and brown and grey markings of the seeds are inherited *independently* of the factors influencing the resistance to wilt.

V. RAMANATHA IYER AND R. BALASUBRAHMANYA IYER (Coimbatore): *A Preliminary Note on the Mode of Inheritance of Reaction to Wilt in* Cicer arietinum.—The reaction to wilt in this crop belongs to the blending type of inheritance manifesting transgressive variation. The type of branching and the colour of the seed coat do not bear any relation with the reaction to disease.

DISEASES OF THE COTTON.

K. N. AMBIGAOKAR AND YESHAVANT D. WAD (Indore): *Studies in Disease Resistance. I.—Cotton Wilt and Environmental Conditions.*—An account of three years' work on the physiology of the cotton plant in relation to wilt. Field observations showed that the progress of wilting in the field may be modified by soil differences, irrespective of its inhibition intensity. Root activity in the upper soil zones was found to be significantly less in diseased plants than in healthy ones. An excessive supply of nitrogen, alone or with phosphate, increased susceptibility. Farmyard manure had no influence.

I. MADHUSUDAN RAO AND YESHAVANT D. WAD: *Studies in Disease Resistance, II.—Leaf-Roll and Red-Leaf in American Cottons.*—Physico-chemical studies of the saps of healthy and affected wilt plants have been made. The pH was greater and the osmotic pressure lower in healthy leaves than in the diseased ones. Studies on soil profiles and the root systems of healthy and affected plants have been carried out in detail. There is generally no visible difference in the soil profiles, under healthy and diseased plants. The root-studies indicate that the high death-rate (as compared with that in normal plants) in the active roots in the upper zone (1 foot) reduce the activity in the roots of lower zone in diseased plants. The disease was produced whenever the surface soil was deflocculated after long continued wetting.

SPIKE-DISEASE OF SANDAL.

M. SREENIVASAYA: *Spike Disease and Resistance in Sandal* (Santalum album *Linn.*) *with Special Reference to its Control.*—The control of this disease presents special problems since the disease affects an extensive crop which takes several years to reach a stage of exploitable maturity. The plant demands during this long period a considerable amount of care and attention by way of tending, host conservation and fire protection. The selection of suitable host plants has proved useful in imparting immunity to sandals effecting rogueing by defoliation has proved useful to detect masking plants. While enforcing methods of plant sanitation has proved helpful in controlling this infectious disease, success has not yet attended the attempts to evolve resistant strains.

B. N. SASTRI: *Physiology of the Spike Disease of Sandal.*—The factors responsible for the accumulation of starch, mannitol and succinic acid in spike tissues have been discussed.

PIRICULARIA ORIZÆ.

K. RAMIAH AND K. RAMASWAMI: *Breeding for* Piricularia *Resistance in Rice* (Oryza sativa).—Breeding work has resulted in obtaining two strains which are not only resistant to the disease but also give a bigger yield than the suscepti-

ble variety. The inheritance studies in this cross would make it appear that resistance to *Piricularia* is a simple recessive.

DISEASES OF SUGARCANE.

C. S. KRISHNASWAMY: *Studies in Disease Resistance in Crop Plants in the Madras Presidency. II.—Estimation of Disease Resistance in Sugarcane Mosaic.*—150 varieties of cane have been tested since 1926 for their resistance to mosaic. The percentage of incidence of mosaic in a variety when interspersed with the diseased cane Co 213, which is taken as standard, gives a measure of the relative resistance of the variety under trial. The studies have shown that immune varieties are rare as even highly resistant varieties are capable of taking up infection under special conditions. An analysis of the factor of disease resistance on morphological and histological characters has been made.

N. L. DUTT, SYED ABBAS HUSSAIN AND M. K. KRISHNASWAMI: *A Note on the Breeding of Sugarcane Varieties Resistant to Mosaic.* As a result of the extensive inter-varietal, inter-specific and inter-genetic crosses, a large number of seedlings are available representing all gradations of resistance, to mosaic, from susceptible to immune. Seedlings which contain the blood of *Saccharum spontaneum* have proved highly resistant or immune, while on the other hand those that do not contain *spontaneum* blood show a high percentage of mosaic infection. With regard to the mosaic resistant varieties, cases have been recorded where the resistance is found to vary geographically. This is perhaps due to the existence of physiologic races of the causal agent.

K. L. KHANNA: *Some Aspects of Disease Resistance in Sugarcane. I.* Plant Vitality, Tentative 'Susceptibility' and 'Resistance' ranges to incidence of pests (shoot borers) and diseases (top rot and red stripe), at different stages of growth, in different seasons and from different treatments such as manures, irrigation and soil types, have been measured and by injecting oxidising agents and certain chemicals and also exposure to component rays of white light, it is possible to raise the vitality of the plants to resist diseases and pests. *II. Morphological and Physiological.*—Some of the characters responsible for differences in varietal predisposition and resistance have been noted. *III. General.*—The relative position of 'major' and 'minor' diseases has been discussed in relation to the rapidly changing varieties as a result of breeding improved types of sugarcane.

SHOOT ROT OF COCONUT.

J. S. PATEL AND A. P. BALAKRISHNA NAYAR: *Natural and Induced Resistance to Shoot Rot* (Gleosporium sp.) *in the Coconut.*—From observations made on large varieties of coconut collected from different parts of the world, and grown at the Government Agricultural Research Station, Pilicode, it is seen that a variety from Philippines showed the lowest percentage of infection (37 per cent.) and a variety from Mysore showed the highest (87 per cent.). The disease occurred in palms 3-9 years of age and thereafter the trees are generally less susceptible. The susceptibility is more pronounced in trees planted on the surface than in the trees planted at a depth of 3 feet. The incidence of disease is considerably reduced when potassium sulphate is applied to the soil.

The Academy of Sciences, U. P.

September 1935. *Special Meeting of the Academy.*—It was resolved (1) to change the name of the Academy to "The National Academy of Sciences, India" and (2) to raise the number of Fellows from 30 to 100.

September 18th, 1935. *Ordinary Meeting of the Academy of Sciences, U.P.*—The following papers were read and discussed:

RADHA RAMAN AGARWAL AND SHIKHIBHUSAN DUTT: *The Chemical Examination of Punarnava or* Bœrhaavia diffusa *Linn. Part II.—The Isolation of an Alkaloid Punarnavine.* B. P. PANDE: *On Amphistomes with Central Pouch from India.* HRISHIKESHA TRIVEDI: *The Absorption Spectrum of Hydrogenchloride Molecule and its Upper Unstable State.*—By the help of a theory developed by the author previously it is possible to calculate the form of the potential energy of the unstable state of hydrogen chloride from the measurements of its absorption coefficient. The form has been known only qualitatively up till now. HAR DAYAL SRIVASTAVA: *New Hemiurids (Trematoda) from Indian Marine Fishes. Part I.—New Parasites of the Sub-Family* Prosorchinæ *Yamaguti,* 1934. HAR DAYAL SRIVASTAVA: *New Allocreadids (Trematoda) from Indian Marine Fishes. Part I.—New Parasites of the Genus* Halicometrina *Linton,* 1910. HAR DAYAL SRIVASTAVA: *New Allocreadids (Trematoda) from Indian Marine Fishes. Part II.—New Parasites of the Genus* Decemtestis *Yamaguti,* 1934.

The Indian Physical Society:

September 21st, 1935. An ordinary monthly meeting of the Indian Physical Society was held at 3 P.M. in the Applied Physics Seminar, University College of Science, Calcutta, with Principal B. M. Sen, M.A., I.E.S., in the Chair. The following papers were read and discussed:

(1) N. K. SAHA (Lahore): *Pressure Coefficient of Electrical Resistance of Metals.* (2) P. LAL AND K. LAL (Lahore): *On the Statistical Theory of Neutral Atoms.* (3) D. V. GOGATE (Baroda) AND D. S. KOTHARI (Delhi): *On the Measurement of the Quantity of Light by the Photoelectric Cell.* (4) K. PRASAD AND B. N. GHOSH (Patna): *Studies on Water Jets.* (5) P. SYAM (Calcutta): *On the Absorbing D-Layer of the Ionosphere.* (6) P. C. MAHANTI (Calcutta): *Fine Structure Analysis of Red Bands of Magnesium Oxide and Isotopic Effect.* (7) P. C. MAHANTI (Calcutta): *Potential Energy Curves and the Structure of the Alkaline Earth Oxides.* (8) S. DATTA AND M. DEB (Calcutta): *Investigations on the Ultraviolet Absorption Spectrum of* Ce^{+++}*ion.* (9) H. P. DE (Calcutta): *State of Polarisation of Continuous X-Rays from a Thin Aluminium Anticathode.* (10) H. P. DE (Calcutta): *On the Emission of Positrons from Bismuth.*

The Indian Chemical Society:

August 1935. H. B. DUNNICLIFF AND BRAHM PRAKASH: *Action of Hydrogen Sulphide on Insoluble Chromates. Part I.—Lead Chromate and Silver Chromate.* S. S. BHATNAGAR, P. L. KAPUR AND N. R. VERMA: *Magneto-Optical Rotation of Uranyl Salts.* R. PADMANABHAN AND S. K. KULKARNI JATKAR: *The Anomalous Rotatory Dispersion of l-β-Pinene—Part I.* B. B. DEY AND T. K. SRINIVASAN: *Studies in the Cotarnine*

Series. Part IV.—5-Bromonarcotine, 5-Bromocotarnine, 5-Bromohydrocotarnine and 5-Bromonarceine and their Derivatives. DUHKHAHARAN CHAKRAVARTI: *Synthesis of Coumarins from Phenols and β-Ketonic Esters. Part III.—Use of Various Condensing Agents.* PHULDEO SAHAY VARMA AND K. S. VENKAT RAMAN: *Nitration. Part V.—Nitration of Monohalogen Derivatives of Xylenes.* PULIN BEHARI SARKAR: *The Chemistry of Jute-Lignin. Part VIII.—Methylation of Lignin.* PULIN BEHARI SARKAR: *The Chemistry of Jute-Lignin. Part IX.—Acetylation of Lignin.* S. M. MEHTA AND (MISS) OLIVE JOSEPH: *The Viscosity of Titanium Dioxide Sol in Presence of Electrolytes.* R. PADMANABHAN: *A Modified Photographic Method for Substances of Small Rotatory Dispersion.*

September 1935. K. VENKATA GIRI: *Studies in Salt Activation. Part II.—Influence of Salts on the Stability of Amylase.* M. M. RAM MOHAN RAO AND S. K. KULKARNI JATKAR: *The Heats of Transition of Triglycerides.* MAHADEO PRASAD GUPTA AND SIKHIBHUSHAN DUTT: *Dyes Derived from Acridic Acid.* SACHINDRA NATH ROY: *A New Volumetric Method for the Estimation of Lead.* RADHA RAMAN AGARWAL AND SIKHIBHUSHAN DUTT: *Chemical Examination of* Cuscuta reflexa, *Roxb. Part II.—The Constitution of Cuscutalin.* NRIPENDRA NATH CHATTERJEE: *Studies in Diphenyl Series. Part III.—A New Route to Phenanthrene.* M. A. HAMID GURCHARAN SINGH AND H. B. DUNNICLIFF: *The Action of Hydrogen Sulphide on the Chromates of Hydrogen, Ammonium, Sodium and Potassium.* RANAJIT GHOSH: *Synthesis of Hexahydro-a-Coumaranone.* B. B. DEY AND (MISS) P. LAKSHMI KANTAM: *Studies in the Cotarnine Series. Part V.—Condensation of Cotarnine with Aromatic Nitro-Aldehydes.* HARISH CHANDRA GOSWAMI AND PULIN BEHARI SARKAR: *On the Triple Nitrites of the Rare Earths and a New Micro-Test for Cæsium.* K. N. KAUL AND G. S. AHLUWALIA: *Action of Cotarnine and o-Nitrobenzaldehyde.* U. S. KRISHNA RAO AND B. L. MANJUNATH: *On the Supposed Occurrence of Acids with Uneven Number of Carbon Atoms in Vegetable Oils and Fats. Part II.—The Acid Fraction of Mean M.W. 354 from the Seeds of* Butea frondosa, *Roxb.* JAGRAJ BEHARI LAL: *Metallic Uranium in Organic Synthesis—Part II.* PRIYADA RANJAN RAY AND HARIBOLA SAHA: *A Short Note on the Chromium Biguanide Complexes.* DUHKHAHARAN CHAKRAVARTI AND BAIDYANATH GHOSH: *Synthesis of Coumarins from Phenols and β-Ketonic Esters. Part IV.—Coumarins from 4-Chloro and 2-Nitroresorcins.* HIRENDRA NATH DASGUPTA: *Heterocyclic Compounds containing Arsenic in the Ring—A Preliminary Note.*

The Indian Botanical Society:

September 1935. T. EKAMBARAM AND I. M. RAO: *Studies in Absorption and Respiration—II.* R. E. COOPER AND S. A. PASHA: *The Osmotic Pressure and the H-Ion Concentration of Sea-Weeds in Relation to those of Sea-Water.* S. C. DIXIT: *The Charophytes of the Bombay Presidency.* J. F. R. D'ALMEIDA: *On the Occurrence of* Gymnogramme calomelanos *Kaulf. in India.*

October 1935. R. H. DASTUR AND M. R. RAUT: *Carbohydrate Nitrogen Ratio of the Shoots of Some Tropical Trees.* P. ABRAHAM: *Occurrence of Extracapellary Ovules on the Floral Axis in Cotton.* A. B. Industrial Outlook.

Fermentation of Molasses: Use of Pure Yeast Acclimatised to Antiseptic.

THE fermentation process with pure yeast is different from that with ordinary yeast because one knows when it commences and when it ends. It is a logical operation—almost mathematical.

For each vat of fermentation the leaven is changed so that the operation is always commenced with vigorous pure yeast. It is easy to understand that in this condition, the bacteria which are in the molasses are entirely subordinate to the yeast. This factor is more marked because pure yeast can tolerate large doses of antiseptics in the special apparatus, whereas the bacteria are completely paralysed by the antiseptics in the apparatus and in the large vats of fermentation. Similarly, if any mistakes occur during the operation of the yeast-apparatus or during its sterilisation, these are negligible owing to the action of the antiseptics.

Yeast which is continually changed enters the fermentation room with the maximum of strength and of diastatic power. The inversion of saccharose is effected in a short period and the transformation of the glucose into alcohol is complete.

The apparatus is so arranged that it is possible to clean it thoroughly twice a day without interruption of the process. This is not possible with the ordinary method of pure yeast culture.

A recent process developed by a French firm adapts laboratory methods of pure yeast culture for industrial purposes, and prevents the "negative phenomena" which up to now have paralysed its development.

DESCRIPTION OF PURE YEAST APPARATUS.

The pure yeast apparatus has an auxiliary equipment which supplies it with a current of purified air.

Supply of pure air which is an essential factor is secured with a pump which sucks air from above the roof of the distillery, and sends it into a filter of steel sheets filled with salycilic-cottonwool. Below the filter is placed a washer, two-thirds of which is filled with clean stones to distribute the air in the antiseptic liquid, kept in the apparatus.

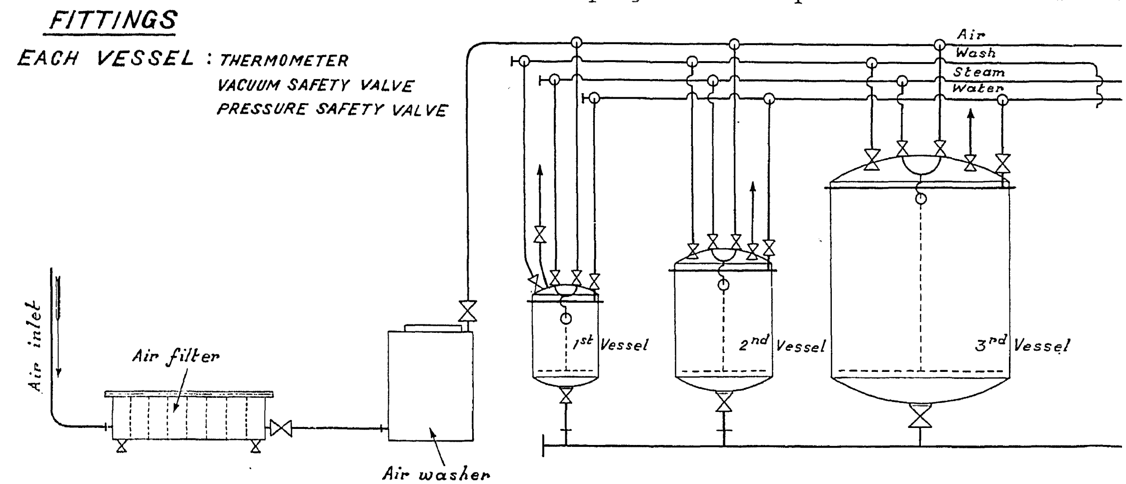
Basins for Culture.—Three basins are available for the culture. They are made of red-copper, tinned inside and have a capacity of 22, 55 and 330 gallons. As each of the three basins must be sterilised, aerated, cooled and connected with each other, they are fitted with 4 sets of pipes. Each basin is fitted with a pipe to convey the sterilised air, and a coil to carry either steam for sterilisation or water for cooling.

On the top of each basin is a manhole, a pipe with a valve for the escape of the gases, and two safety valves. A thermometer fitted to each apparatus enables the variations in temperature to be watched.

The basins are connected with each other at the bottom by a pipe which can serve (1) as an outlet for the yeast, (2) as an inlet for the wash, (3) for cleaning the apparatus, and (4) as an inlet for water and steam. The piping can be sterilised completely in an easy manner.

Each basin is fitted with two cocks for withdrawing samples, with a view to watching the fermentation.

It is easy to visualise with the help of the accompanying diagram how this equipment (manufactured by Ateliers Pingris and Mollet Fontaine Reunis, Lille, France) is operated to furnish a steady supply of pure yeast by progressive multiplication in the three basins.



DIAGRAMMATIC ONLY

The high content of the antiseptic and the strength of the yeast permits of the stoppage of the development of bacteria until the vat is filled. During this period, the yeast apparatus continues to furnish fresh yeast and every 14 hours a pitch tank will be ready for a new fermentation.

If the yeast apparatus is correctly operated, it can run continuously without changing the yeast for a period of 3 to 4 months, and the efficiency from actual experience in India, reaches more than 90 per cent. of the theoretical.

Ninth Conference of the Indian Mathematical Society.

THE Editor, *Mathematics Student*, writes:

We beg to remind our readers of the Ninth Conference of the Indian Mathematical Society which meets at Delhi at the invitation of the Delhi University between the 19th and 21st of December (both inclusive) this year. It is hoped that a large and representative body of members will participate and ensure its success. Those who intend attending the Conference are requested to communicate with Dr. Ram Behari, M.A., Ph.D., Professor, St. Stephen's College, Delhi, who is the Chairman of the Local Committee. As the programme will soon be printed, it is requested that abstracts of papers intended for the Conference be sent to Dr. A. Narasinga Rao, Professor of Mathematics, Annamalai University, Annamalainagar, without delay.

Reviews.

THE USE AND MISUSE OF LAND. By R. Maclagan Gorrie. (Oxford Forestry Memoirs, No. 19, 1935.) Pp. 80. (The Clarendon Press, Oxford.)

It was long the fashion for the Agriculturist to think of the Forester as his natural enemy. This view, born of ignorance, is gradually disappearing but not yet dead. There is as yet, however, no widespread appreciation and occasionally not even recognition that sound Forestry instead of being incompatible with flourishing Agriculture, is an important and even integral part of it. The Forester and the Agriculturist are both vitally interested in the quality and quantity of their common basic commodity—the Soil. But, strangely enough, books which take a long-term view of Forestry and correlate its fundamental bearing to soil are all too few. It is for this reason that Dr. Gorrie's interesting Memoir is to be welcomed.

The book deals primarily with grazing and its relation to Soil Erosion. Indeed, the author who at first set out to trace "The Correlation of Erosion Damage and Grazing in Forest Lands" subsequently enlarged the scope of his enquiry because he felt that "if land as a whole could be put to its best uses......the menace of overgrazing would automatically disappear". The value of Dr. Gorrie's book lies as much in this significant standpoint of the author as in the suggested solutions of the problem. Much the greater part of the data in the book relating to Land Erosion are from the United States and some at least of the lines of attack interest us in India as showing how the problems are tackled elsewhere rather than as how they should be here. Such concepts as "Palatability" of fodder to livestock, "Forage Factor" (defined as, Average Type Palatability × Average Type Density) dealt at some length in the Memoir are of little more than academic interest to the Indian student.

The volume opens with a fascinating account of "Forestry as a Factor in Land Management". A survey of some aspects of grazing leads the author to a consideration of Grazing as a primary cause of Soil Erosion. The control of stream flow is then discussed and there is a separate chapter on "Farm Erosion and its Control". The title of the last chapter "Public and Private Control of Land" almost suggests a discussion of socio-economic theories of land ownership of which, however, the author steers clear and gives short accounts of Erosion Control and Regional Land Planning as practised in the United States.

The use of the expressions "concave upwards" and "convex upwards" in describing Soil Profiles (p. 38) is a little jarring. The units employed in the tables are not always happy. Thus land erosion in Table I (p. 50) is expressed in "cu. yds. per sq. mile" while in Table II (p. 51) the soil loss is quoted in "tons per acre". A couple of Americanisms, "on to which" (p.74) and "Alinement" (p. 76) are noticeable.

A bibliographic list is given at the end of each chapter. But for a semi-jocular reference to Wang's "Grundriss der Wildbachverbauung" in the text (p. 49) and a reference to Cabianca's paper (p. 60), the selection ignores the work of the Continental schools of thought. A few appropriate references to the pioneer work of the great German and specially Russian pedologists would very considerably add to the value of the Bibliography.

The Memoir should be read by every one interested in the intelligent utilisation of land.

EMMENNAR.

THREE PHILOSOPHERS. By W. R. Aykroyd. (William Heinemann, Ltd., London, 1935.) Pp. 227. Price 10*s*. 6*d*.

In the history of every nation there are periodically recurring moments when the nation wakens to a national consciousness. To the French people such a historic moment came, when the public discovered the injustice of the verdict of the sanguinary Tribunal of the Revolution, to guillotine Lavoisier. The story of the life and work of this pioneer of modern chemistry makes fascinating reading to which a pathetic turn is given by the exceptionally tragic circumstances that attended his end.

In the present volume, the author gives primarily a biography of Lavoisier to which are added the lives of the two eminent English scientists, Priestley and Cavendish. These latter two were Lavoisier's contemporaries and rivals in the field of science. As an excuse for the inclusion of these two biographical sketches when his main purpose seems to be to lay bare the rather unfamiliar

life-history of the French scientist, the author suggests that the achievements of no scientific worker can be studied with advantage without reference to those of his contemporaries whose work no doubt must dovetail with his own. This method is amply justified in as much as certain obscure points in regard to claims for priority of discovery raised by some biographers have been set at rest. The lives of the three great figures of modern science are pursued on parallel lines and wherever appropriate, their attainments as men and scientific workers are critically compared.

Lavoisier came from the solid middle class and had a good start in life. The family traditions would have shaped out an entirely different course for young Lavoisier, but his native genius triumphed and made him elect a scientific career. To him the attainment of scientific distinction was of paramount importance. His chief claim to our remembrance and admiration rests on the laurels he won in the field of science, though he rendered signal service to the state and society as an administrator of the Revenue Farm and as the able head of several commissions on social reform. To Priestley all the advantages which birth and wealth could give were denied by nature, and his early education took place in an atmosphere of dissenterism. So it is small wonder that his mental horizon was dominated by theology in the light of which all other considerations were unworthy of serious attention. The scientific career of Priestley was spasmodic and all his major discoveries were made in fits and starts. Scientific research to him was a source of profound amusement that could fitly occupy his leisure. Like Saul, who came upon a kingdom when he was seeking his father's asses, he stumbled upon great discoveries. The history of the social life and scientific career of Henry Cavendish is a study in contrasts. Although coming of an aristocratic stock he inherited none of the gifts that go to make men successful in society. Aversion to society and in particular to women, was but one among a host of curious sadistic tendencies. Strange tales are current of how he avoided all contact with women. Coupled with this remarkable psychosis was an intellect, which, to say the least, was of the first rank. Science was the one light that relieved the genuine gloom of this singular mind.

Apart from the biographical interest in the book the serious student of chemistry finds much food for thought. The refutation of the infamous theory of "phlogiston" which was obstructing the progress of chemistry for more than a century, by Lavoisier and unwittingly by Priestley himself has been developed at length in its historical and logical sequence. Another topic of general interest is the establishment of the composition of water by Cavendish, which is all the more striking as nothing like scientific technique existed then. Lavoisier was the first to study metabolism and related phenomena which have culminated in the vast and fruitful science of Nutrition.

The background of these biographies is undoubtedly the troubled times of the latter half of the eighteenth century. The lives of at least two of the personages are coloured by the French Revolution, and unfortunately one of them was victimised by its bloody tyranny. The passages where the Reign of Terror is depicted, speak eloquently of the author's abilities as a descriptive writer. The mock trial of the Revenue Farmers before the Revolutionary Judges is at once vivid and pathetic in the extreme.

Like many a great man Lavoisier owed in great measure his success to the unremitting devotion of his wife. Any sketch of his life would be incomplete without a reference to Marie-Annés who was his collaborator and inspirer. The author has done her ample justice by clearly indicating the nature of the co-operation which subsisted between them, which in great measure contributed to their joint successes. In the closing chapters of the book her history after the death of Lavoisier is narrated which serves to vindicate her character though she accepted the suit of the Count Rumford.

Speaking of the style of the author we admit without hesitation, that, though he is a specialist in a highly technical branch of science, his power of exposition may well be coveted by any literary man. The narrative is very lucid and is enlivened by anecdotes relating to incidents in the lives of these three scientists. English writers have meted out scant justice to Lavoisier who has been accused of appropriating others' discoveries to his credit. But in Dr. Aykroyd the French Chemist finds an enthusiastic champion.

Of the essential accomplishments for good citizenship, one of the most necessary factors

is perhaps the development of the historical sense. Among those that foster the cultivation of this sense most are the biographies of great men who have contributed to the public weal. To all those who wish to make a beginning in this direction Dr. Aykroyd's *Three Philosophers* is eminently suitable. The book provides the necessary background and the materials to build upon. The multiplication of such books will obviate the keenly felt desideratum as the literature of this kind is none too profuse. Meanwhile we extend our most cordial congratulations to the author for having won this signal distinction in the field of the professional historian.

HEREDITY AND THE ASCENT OF MAN. By C. C. Hurst. Cambridge. (The University Press, 1935.) Pp. ix+136. Price 3*s*. 6*d*. net.

Human history is in reality only a special aspect of natural history, dealing with the succession of events having to do with the human species. It is continually asked, what has man been doing through the long ages of his existence? The answer is furnished in part by the answer to the even more fascinating question—what will he become in the ages to come? Modern research in biology has taught us that minute particles of living matter with definite composition pass unchanged from generation to generation. We have learnt further that the human individual is extremely complex and is made up of materials, which while deriving their salient traits from ancestral germ-plasm are arranged in new ways so that it is rarely possible for two individuals to come into the world with the same inheritance of living stuff. In the fifties of the last century Gregor Mendel, an Austrian abbot, discovered the fundamental unit of life and mind the 'gene', but like many a great discovery it was completely ignored by Mendel's contemporaries. It was not until the beginning of the present century that scientists accorded to this discovery full recognition, for want of which biologists found themselves confronted by well nigh insurmountable difficulties. Since then the progress of genetics has been both steady and considerable. Among the experiments whose work has contributed most to this progress, the name of Dr. Hurst stands pre-eminent, whose work *Experiments in Genetics* has been considered to be a classic in the field. The present book is a sequel to this more elaborate work, and is a very popular epitome of the recent work and achievements of the geneticists.

The book is devoted to a description of the fundamental unit of life and mind—the gene—which is the determining factor in the behaviour of all living organisms. Authority is implicit in this narration inasmuch as the author is a man of science and of recognised authority. The enthralling story of the evolution of living things is told in plain and simple terms making it intelligible to the lay reader. An unique feature of the book is that interesting speculation is set forth concerning the future of the human race. The author by a consideration of experimental facts comes to the universally interesting conclusion that the genetical work of the past few years may bestow freedom and power on man to shape his destiny. This sounds in striking contrast to the classical saying that "there is a Divinity that shapes our ends". Another thesis of especial interest to the statesman is that the nation which adopts scientific methods of race improvement will inherit the earth. Recent events in countries such as Germany, Turkey and Italy, under dictators, have at least in part justified this claim.

It is impossible to emphasise the importance of genetical science to the horticulturist and the breeder, but the aim of the author in this book seems to be to attract the man-in-the-street whose interest in this subject must be aroused and inspired to pursue the study at greater length. It will not be too much to expect that the volume will make an instant appeal to all those who wish to acquaint themselves with what is going on in one of the most rapidly progressing branches of biological research which has done so much to change the order from natural selection to human selection and enabled man to take a hand in creative evolution.

COSMIC RADIATION. By Prof. P. M. S. Blackett. Part I—General Survey. 22 pages. Price 10 *fr*. Part II.—The Wilson Cloud Chamber Method. 24 pages. Price 8 *fr*. Part III.—The Effect of the Earth's Magnetic Field. 19 pages. Price 7 *fr*. Part IV.—The Loss of Energy by Ionisation. 17 pages. Price 10 *fr*. (Actualités Scientifiques et Industrielles. Hermann et Cie, 6, Rue de la Sorbonne, Paris.)

These papers were read before the four conferences on Cosmic Radiation, held in

May 1934 by the College of France in Paris, and have been printed practically as read. It is unfortunate that they were not published more than a year earlier. They contain in concise form an account of the main lines of development of our knowledge of cosmic ray phenomena and would therefore prove valuable to those who wish to view this field through the eyes of one who has had a share in its development.

The introduction to the subject in the first paper begins with a quotation from an enthusiast who wrote without exaggeration: "Cosmic Radiation is a subject unique in modern physics, in the minuteness of the phenomena, the delicacy of observations, the adventurous expeditions of the observers, the subtlety of the analyses and the grandeur of the deductions."

After a very brief historical statement, there follows a correspondingly condensed account of cosmic ray intensities at various depths below the top of the atmosphere and under water in deep lakes, as measured by ionisation chamber methods. Intensity variations with time; geomagnetic latitude and longitude and their significance are discussed. It is pointed out that these data leave little room for doubt that the primary rays are electrically charged particles. Results obtained by means of counter-tube controlled cloud chambers are discussed in a little more detail and the paper ends with an all too brief consideration of the origin of this mysterious radiation.

The second paper should be of special value to those who wish to do experimental work with cloud-chamber apparatus. It begins with a discussion of the formation of tracks, their width, number of ions per unit length, and other matters. A few details of construction of apparatus used by the author are given. The latter half of this paper is devoted to a discussion of the production of "showers" and "bursts", investigated chiefly by means of Geiger-Muller counter-tubes.

The author shows that observations are best explained by assuming that electrically charged primary rays of high energy, in their passage through matter, produce at intervals, along their paths, a non-ionising radiation of the gamma-ray type, which in turn is absorbed with the emission of positive and negative electrons which ionise all along their paths. The production of a relatively small number of these tertiary rays at one time is called a shower but, occasionally as a result of some catastrophic process, millions of these tertiary rays are produced and this is spoken of as a "burst". It is not clear that these two phenomena are of exactly the same type. In all cases it seems certain that practically all the energy involved in these phenomena comes from the primary particles.

The subject-matter of the third paper is especially important because it shows very conclusively that the primary radiation consists chiefly of electrically charged particles, most of which are positive. The author deals at some length with the theoretical work of Störmer and of Lemaitre and Vallarta, *i.e.*, with the motion of high-speed electrons and protons in the magnetic field of a di-pole, the earth. Observational results, in the light of theory, indicate clearly that only a small percentage at most, of the softer portion of the penetrating radiation can possibly be of terrestrial origin, while all of the harder rays must come from beyond the confines of our own galactic system. Thus the term "cosmic radiation" seems to be fully justified.

The fourth paper deals with the various processes by which the energy of a cosmic ray particle is dissipated while passing through matter. The cosmic ray may (*a*) cause excitation or ionisation by passing near an electron in matter; or (*b*) directly hit an electron giving rise to a secondary high energy ray; or (*c*) make a direct collision with an atomic nucleus, resulting in the production of many high-energy photons, as mentioned above, and probably other complications.

For process (*c*), the effective area of cross section is only a small fraction of the area of the nucleus of the atom concerned, while in the absorption of the photons, the effective area is proportional to the atomic number, which in the case of heavy elements is many times greater than the area of cross-section of the nuclei.

In such papers as these it is of course impossible to give details of construction and use for the many types of apparatus mentioned. For such information and indeed for any serious study of the subject a bibliography listing more than a hundred well-selected papers is appended. Another worthwhile feature of this work is a set of fifteen excellent reproductions of some remarkable cloud-chamber photographs by C. D. Anderson and of several by the author.

J. M. BENADE.

LES SPECTRES DES NEBULEUSES GAZEUSES. Par P. Swings. (Actualités Scientifiques et Industrielles. No. 241, 1935.) Pp. 1–26 Prix. 10 *fr*.

This is perhaps one of the smallest volumes in the Actualités collection running to twenty-six pages only out of which 15 pages are devoted to a table, two appendices and the title pages. It is remarkable that in the remaining short space of 11 pages the author should be able to present such a clear and up-to-date account of the subject. This has been made possible because in the first place the author himself has done, in collaboration with B. Edlén, very important work in this field and in the second place there already existed the beautiful article of Bowen (*Ap. J.* 1935, 81, 1) giving a synthesis of the ideas on the subject.

The author treats fully the mechanism of excitation consisting of primary process of ionisation by absorption of stellar radiation and the secondary processes of ionisation by secondary radiation, excitation by the same and excitation by secondary electrons. On the other hand, the treatment of that part of the subject dealing with chemical composition must certainly be considered to be inadequate although the author has given a resumé on p. 16. It might be remarked, in passing, that this resumé reads almost like a literal translation of the first paragraph on page 16 of Bowen's article mentioned above.

B. S. M.

* * *

DE'NOMBREMENTS D'E'TOILES. Par H. Mineur. (Actualités Scientifiques et Industrielles. No. 225. 1935.) Pp. 1–56. Prix. 15 *fr*.

This volume forms, as the author states in the preface, an indispensable complement to the volume on the measurement of positions and magnitudes of stars which has already been reviewed in these columns (*Curr. Sci.*, 1934, **3**, 223). The attempt to condense in a short space the very latest work done in the field has resulted in making the treatment necessarily sketchy and the material is not presented in a logical sequence as was done in the author's volume on "Photographie Stellaire". There is neither a table of contents nor an index nor a bibliography.

The work is, however, quite authoritative and there are no errors of a serious nature. The large number of tables and graphs interspersed throughout the volume adds much to the clarity of the exposition. Of particular interest is the representation, by means of formulæ, of the number denoting stars more brilliant than magnitude m, as based on the work of Chapman and Melotte, Van Rhijn and Seares. As a preliminary to the actual subject of star counts, the author has briefly reviewed the principal star catalogues and charts and assessed their relative importance from the point of view of Stellar Statistics. Importance has rightly been given to the Harvard photometric sequences, this being the source on which the author mainly relies.

This is an indispensable book for an astronomer, theoretical or practical.

* * *

PHENOMENES D'INTEGRATION DANS LES CULTURES DES TISSUS. By B. Ephrussi. (Actualités Scientifiques et Industrielles. Hermann & Co., Paris, 1935.) Price 8 *fr*.

Tissue Culture, undertaken mainly by workers on Cancer Research, has, in practice, involved the solution of many problems of General Biology. One such problem, as Vogt puts it, is "the individuality of cellular culture....... After several transplantations what type of formation is represented by a culture of fibroblasts?...... Is it a Unity like that of the whole organism or a part of the organism?" We venture to paraphrase it in common language as follows: Is it (the culture of tissue cells after several transplantations or passages) a chip of some block or are there as many blocks as there are chips or cells? Albert Fischer, the author of the best book on Tissue Culture, so well qualified to speak on such a problem, says in one of his papers, "The transplanted tissue obeys all the laws of physiological integrity....... We are here dealing with a partial organism and not with cellular organisms." The reasons for such an opinion have been based on certain differentiations which appear among cells on culturing a tissue. For example, the epithelium of the Thyroid begins to form the colloidal substance only in the centre while the cells on the periphery of the same culture continue to multiply undifferentiated. M. Ephrussi rightly compares a culture of tissue to an organism, for cells sometimes show division of labour even though the main function leading to the division of labour may not be apparent; he calls this oriented heterogeneity. He summarises the following points of identity between the

culture of tissue cells and an organism as a whole: (1) The tendency towards a definite shape. (2) The limit of sub-division (for single cells of tissue do not grow). (3) The power of regeneration which naturally regulates the shape. (4) Oriented heterogeneity. M. Ephrussi further finds two problems common between the science of Tissue Culture and General Biology: (1) What limits the growth of a tissue in culture? and (2) What determines the development of a cell? That there is a regulating factor inherent in a culture of tissue is inferred by the presence of a similar substance in a colony of Vorticella as previously shown by the renowned French Biologist, Faure Fremier, under whose editorship the present brochure has been issued. Such a substance, although hypothetical at present, is probably also found in an egg where it regulates the growth of the embryo. M. Brachet has called it "Genetine". M. Ephrussi has given a clear exposition of the subject within 22 pages of printed matter using some 10 diagrammatic figures for illustrating the important points. For the modest price of 8 francs nothing more could be expected but many a reader would have welcomed a longer essay perhaps with some microphotographic illustrations which would have given a more realistic representation of the phenomenon discussed so ably by the author. The subject appears to be of very recent origin, for no paper in the bibliography dates earlier than 1922.

S. M.

* * *

HEAT. By Hutchinson. (University Tutorial Press, Ltd., London.) Pp. 284. Price 3*s.* 6*d.*

This is an excellent work by a well-known author and fits in admirably with the Intermediate syllabus of Indian Universities. The chapter on "Radiation" is the only chapter where the author could have adopted a fuller treatment by the addition of the "Theory of Exchanges" and Richie's experiment.

A historical background is provided throughout the book by detailed description of classical experiments. The utility of the book is greatly enhanced by the mention of all the practical applications of heat in industries and engineering. Heat engines have received particular attention in the last chapter.

The worked and unworked examples are as interesting as they are varied in type. Solutions to the examples are, unfortunately, omitted and would be a welcome addition to the book.

One cannot help wishing that the cover of a book, whose get-up in other respects is excellent, were of a different colour. The bright orange cover "strikes" one in the eye. Would not a light green or blue be more suitable for a study?

P. A. MADHAVA RAO.

* * *

ORGANIC SYNTHESES. Vol. XV. Edited by W. H. Carothers. (Messrs. Chapman & Hall, London, 1935.) Price 8*s.* 6*d.* net.

The book under review is the fifteenth member of the series of publications entitled "Organic Syntheses". The present one contains description of usefully workable methods of thirty different preparations. The inclusion of substances like 5 : 5-dimethyldihydroresorcin, diazomethane, 2 : 4-dinitroaniline, *p*-iodophenol, 1-methyl-2-pyridone, etc. and an experiment describing the preparation of anhydrous hydrogen bromide, obtainable continuously for hours, make the book quite useful. Amongst the types of reactions dealt with in the present volume are to be found examples of (1) addition of hydrocyanic acid to a ketone, (2) substitution reactions, (3) reduction with tin and hydrochloric acid, (4) Grignard's reaction, (5) malonic ester condensation, (6) decarboxylation with concentrated alkali at high temperature, (7) halogenation with halogen acids, and (8) oxidation with selenium oxide. The get-up of the book and the disposition of the contents are exactly as in the previous volumes.

P. C. GUHA.

* * *

LABORATORY MANUAL OF PHYSIOLOGICAL CHEMISTRY. By Prof. Meyer Bodansky and Marion Fay. Third Edition. (John Wiley & Sons, Inc., New York; Chapman & Hall, Ltd., London, 1935.) Pp. vii+274. Price 10*s.* net.

This is the laboratory companion to Professor Bodansky's well-known *Introduction to Physiological Chemistry* (*cf.* review in *Current Science*, 1935, **3**, 318) and the latter should be consulted at every stage to understand the bearing and significance of the experiments dealt with. As an elementary laboratory manual useful to students preparing for a degree in Medicine, the book serves a real need. It comprises both qualitative and quantitative experiments, systematically arranged. The subjects dealt

with are few, but vital and within the limits imposed by the size of the manual; the authors have succeeded in placing before the readers, a comprehensive array of the salient features of physiological chemistry. While the book cannot lay claim for completeness, it serves as an excellent introduction and if supplemented by collateral reading of easily accessible literature with the assistance of the references cited throughout the book, the student cannot fail to obtain a working knowledge of the subject.

The get-up of the book is excellent and leaves nothing to be desired. We are confident that the revised edition will receive a warm reception.

* * *

INSECT PHYSIOLOGY. By V. B. Wigglesworth. (Methuen & Co., London.) Pp. viii + 134 with 13 Illustrations. 1934. Price 3*s*. 6*d*.

This little book maintains the high standard reached by other monographs on biological subjects published by Methuen & Co., Ltd. It will be welcomed by the agricultural and medical professions and will be of great value to students of general zoology. The general physiology of the group of Insects which are the most numerous in species and the most varied in structure and habits, is apt to be observed by the practically endless specializations of these animals, but the author has retained only the material points, linking all the general factors into a single system, in illustration of his theme.

Though the early scientists like Hooke, Malpighi and others have studied the morphology of insects and have given us correct and valuable information about their physiology, the subject did not receive further attention nor any impetus till entomologists were confronted with the ravages caused by the insects in the spheres of agriculture and public health. Subjects like responses to stimuli, reactions to parasites, acclimatisation and the action of toxic sprays and gases upon these, have engaged the attention of economic entomologists within recent years. We, therefore, congratulate Dr. Wigglesworth and welcome his largely illustrated monograph in which the author says that "the sketch which follows is based on the study of nearly 2,000 publications, and on a certain amount of original work".

The first chapter deals with the integument and it is very well known that a large amount of insect physiology depends upon the nature of its cuticle. The cuticle which consists of thin epi- and a thick endo-cuticle is shed from time to time. The unimpregnated endocuticle is very elastic and this is proved by the fact that the first stage larva of Rhodnius can receive into its abdomen more than 12 times its own weight of blood. During moulting, a large part of the cuticle is dissolved; the endocuticle when unimpregnated with cuticulin undergoes dissolution, when the epicuticle remains untouched. Possibly this digestion of the cuticle is brought about by the secretion of enzymes (a chitinase or protease) by the dermal glands into the moulting fluid present between the new and old cuticle. The epicuticle is torn by the pressure of the blood. Chapters II and III deal with the respiratory and circulatory systems. The diffusion theory of insect respiration is briefly described and an account of the respiration in aquatic forms like Hydrophilus, Dytiscus (metapneustic respiration) and Notonecta is given, and among parasites mention is also made of the aquatic larva of Donacia possessing special siphons which are inserted into the air-containing tubes of aquatic plants, and thus remain submerged permanently. The wounds in many insects are merely closed by a plug of cells and the blood does not clot in that region. The blood-cells or hæmatocytes are phagocytic and accumulate on the sides of the dorsal blood-vessel forming phagocytic organs.

In the chapters on digestion and excretion, besides giving important and interesting information regarding salivary glands, the author has given excellent description of digestive enzymes, Malpighian tubules, the holocrine and merocrine types of secretion. The former is a cellular disintegration to form the juice while the latter is merely a secretion from the epithelium.

The next two chapters deal with nutrition and metabolism, and reproduction and growth. The importance of symbiotic organisms is discussed in insects like Cimex, Glossina and Pediculus. With regard to the subject of metamorphosis, it is believed that this is initiated by a harmone which is different from the one responsible for moulting.

The last chapter gives an account of the nervous system, sense organs and behaviour. There is a large list of references given at the end of the book so that students requiring detailed information may refer to the original papers. The get-up of the book

is neat and attractive and we have no doubt that it will be appreciated by the scientific workers for whom it is intended.

HELMINTH PARASITES OF THE DOMESTICATED ANIMALS IN INDIA. By G. D. Bhalerao. (Scientific Monograph No. 6 of the Imperial Council of Agricultural Research.)

The study of helminthology has, in recent years, revealed its importance not only in medicine and public health, but also in veterinary and agricultural sciences. Unfortunately this branch of science has, till recently, been neglected in India. Mr. Bhalerao's Monograph on the "Helminth Parasites of Domesticated Animals in India" has adequately put forward its claims in veterinary science and is a valuable asset to the helminthologists and veterinarians alike. The aim of the monograph is to provide a collective account of the helminth parasites of our common domestic animals and to facilitate their identifications. Each helminth group—Trematoda, Cestoda, Nematoda and Acanthocephala—is considered separately, beginning in a general way with the morphology and life-history, followed by a systematic account of the group under review. Elaborate keys for the identification of the parasites belonging to each group form very useful part of the work. The descriptions, though concise, are suitably illustrated by clear diagrams, many of which are claimed to be original. The bibliography given at the end of the book is exhaustive and renders the volume of service even to advanced workers. The author has successfully achieved his object and the work compares favourably with any other in the field.

No work of this kind can be perfect in every way and there is always a danger of its becoming out of date, even prior to its publication, especially when continued research is daily adding new forms to the helminth fauna. There appear to have been certain omissions and unfortunate errors in this volume. The author has been rather modest in omitting his important forms described in recent years. In the interest of the subject, these and certain others described by other authors from India ought to have been included in the book. Mention of the presence of receptaculum seminis in the family Psilostomidæ is rather curious, as its absence has been emphasised in many standard works (*vide* Führmann in Kükenthal's *Handbuch der Zoologie*). There are some slips as well and these though trivial, are blemishes in an otherwise admirable piece of work.

The general get-up of the book is nice and the paper used is good. The book is particularly welcome as it comes from the Research Staff of the Imperial Institute of Veterinary Research, Muktesar, where most of the officers of the Veterinary Department now complete their training. Mr. Bhalerao is, therefore, to be congratulated on this successful venture of a zoologist. The book is the first of its kind from India and will undoubtedly well serve the purpose intended. It should meet the requirements of both the student and the practising veterinarian, and would, besides, form a useful addition to the zoological libraries.

* * *

FUNDAMENTAL PHYSICAL PROPERTIES OF LAC—PART I. MECHANICAL PROPERTIES. By Lal C. Verman. (Technical Paper No. 3. London Shellac Research Bureau.) Pp. 28.

This neat brochure heralds the publication of a series of four dealing with various aspects of the Fundamental Physical Properties of Lac, *viz.*, Mechanical Properties, Thermal Properties, Electrical Properties and Optical Properties. It was pointed out by Mr. Gibson, sometime ago, that, among other things, compilation and publication of exact data on the Physical, Chemical and Mechanical Properties of Shellac, with special reference to use in industrial processes, would go a long way to consolidate the position of lac as a raw material in industry ; Dr. Lal C. Verman has taken great pains to collect and collate the floating facts and present them in such a concise form for ready reference. After a brief outline of the methods and their limitations, values are given for the specific gravity of shellac, film-hardness, adhesive strength, ultimate tensile strength and modulus of elasticity of various types of shellac and shellac compositions. Wherever possible the corresponding values for other natural and synthetic products are also given for comparison.

A perusal of this booklet brings to light certain striking properties of lac which can be turned to commercial exploitation. The removal of the wax from lac seriously impairs the scratch-hardness and abrasion resistance of shellac films, and the author's own work indicates that the natural wax is far superior to added plasticisers in conferring hardness and especially abrasion resistance

to shellac films. It has been clearly pointed out that the hardness of the film depends on the nature of the base to which it is attached and the subsequent baking. Another remarkable property of lac brought into strong relief is that its adhesive quality is something enormous compared with fish glue and gelatin, the drying period being relatively negligible at that. In spite of this the film produced from shellac varnish can be "flatted" by sand-paper. An adequate bibliography at the end considerably enhances the usefulness of this brochure.

This publication is all the more welcome at this juncture when lac is faced with a crisis. By bringing to the fore the outstanding qualities of lac, it may help the lac industry to hold its own against the onrush of synthetic products. It is hoped that, ere long, the other parts also will come in print.

* * *

INDIAN SUGAR INDUSTRY (1935 ANNUAL). By M. P. Gandhi, Secretary, Indian Sugar Mills Association; Secretary, Indian Chamber of Commerce, Calcutta. (G. N. Mitra of Messrs. Book Co., Ltd., 4/3 B, College Square, Calcutta.) Pp. xvi + 57 + 22. Price Rs. 2–4–0 (postage extra). Foreign *7s. 6d.*

At the time when the Indian Sugar Industry is making rapid strides of advance under the Government's protection policy with all its beneficent influence on the agriculture of the country, this publication by Mr. M. P. Gandhi must be of immense interest to industrialists as well as to the general public. The author has presented briefly all sides of the industry and its inherent problems. The earlier part of the book contains tables of all the necessary data about production, exports, imports, costs, consumption and many other pertinent topics. The main text confines itself to a detailed explanation of practically the same topics with the author's views and arguments. The reader has herein an opportunity of knowing a short history of this important industry, its present position and the future possibilities.

The fifteen tables inserted in the book are useful as permanent references because they include besides the figures for the year under consideration those for several of the preceding years and also here and there estimates for the coming years. The appendix contains an outline of world sugar industry with a special section on Java. The monograph ends with a very useful list of all the sugar factories in India.

For purposes of easy comparison quantities must be expressed in the same unit, for example, as tons or as maunds and though it is appropriate to use both the units it will make comparison of data more difficult. We find also different ways of numeration adopted even in one and the same table as for example in Section (9) of "The Indian Sugar Industry at a Glance" where the quantity of cane crushed is expressed as lakhs of tons and other quantities as millions of tons. Attention to these small details is bound to enhance the value and usefulness of the work.

It is hoped that the author undertakes this publication every year for the use of the public who are interested in the welfare of one of our important national industries.

G. G. R.

* * *

CANDLE MANUFACTURE. By Professor Dr. N. N. Godbole, assisted by R. N. Mehta. (Benares Hindu University, Benares, 1935.) Pp. iv + 29. Price Rs. 2. Foreign *4s.*

This small book of 29 pages embodies the practical experience of the authors in the industrial laboratories of the Benares Hindu University and also includes information collected elsewhere.

The first chapter presents a brief survey of the historical and economic aspects of the industry. The raw materials of the industry are described in the second chapter, which gives in addition an elementary idea of the process of the "splitting" of fats and hydrogenated oils. Auxiliary materials such as ceresine and bees-wax as well as the recently developed I-G waxes, and their assistance in the manufacturing process are indicated in the fourth chapter.

A short account of preparation of candle-wicks and the significance of the melting and congealing point of candle-material is followed up by a very brief description of the manufacturing process as carried out with modern machinery. Some hints are also given regarding the manufacture of fancy material such as coloured, medicated or perfumed candles.

The tables given in the appendix contain information concerning (1) size of wick and diameter of candle, (2) shape, size and weight, and (3) melting points of some types of candle-material.

It is hoped that this book will be read by all persons interested in candle manufacture.

UNIVERSITIES YEAR BOOK, 1935. Published for the Universities Bureau of the British Empire. By G. Bell & Sons, Ltd., London, 1935. Pp. xxxi+1057.

The latest edition of this well-known year book has all the merits of its predecessors, authoritative character, comprehensiveness and excellent get-up. First published in 1914, the Year Book has become more and more indispensable to the members of universities and colleges, government departments, clubs, school masters, etc., who find in it much information of interest regarding members of other universities, colleges, etc. The publication has been brought up-to-date and the arrangement of matter is so designed as to make ready reference possible and in this, considerable assistance is afforded by the excellent name and general indices.

Each section under Universities (of Great Britain and Ireland, of Canada, of Australia, of South Africa and of India) comprises a directory of the officers and members of the staff of the universities, general information and reports of events of outstanding interest which occurred during the previous year. There are 31 appendices, which provide such varied information as professions and careers, post-graduate scholarships, centres of scientific and industrial research, etc. Considerable space is devoted to Indian universities not only in the earlier chapters, but also in the appendix. The publication is indispensable to all libraries where it will occupy an important place among reference volumes.

* * *

LES ASSOCIATIONS BIOLOGIQUES AU POINT DE VUE MATHEMATIQUE. By M. Vito Volterra and M. Umbreto D'Ancona. Pp. 97, 28 Figs. (Actualités Scientifiques et Industrielles. Hermann & Co., Paris, 1935.) Price 20 *fr*.

This brochure is a guide to the study of the rise and fall of population among animals and lower organisms by the application of mathematics. The late E. F. Smith, the author of *Bacterial Diseases among Plants*, who has done more than any one else to increase our knowledge in this branch of science and as such deserves to be considered a great biologist, says in his book, "Nothing is more discouraging to the general reader than a book or paper full of mathematical formulæ." He further writes, "Biologists, for the most part, are very far from being able to express themselves after the manner of mathematicians. Their language and ours is unlike almost to mutual exclusion. If your liking for mathematics is second only to your love of biology, then you may study it as long as you feel inclined. You will be a kind of white blackbird among your fellow biologists but this need not disturb you since you will be able to do some things which they cannot do." If any ambitious biologist wishes to make himself such a "white blackbird", he cannot do better than start with the work of Volterra and D'Ancona under review for it gives as easy and simple an introduction to the subject as possible. Volterra's mathematical theory of the struggle of life has proved of such significance that it has offered others like Gause and Severtzoff material to elaborate on. Master of his field Volterra's treatment of the subject can hardly be surpassed in lucidity and selection. However, as the authors themselves state, their publication, on account of its small size, can hardly serve as anything more than a guide and they refer the interested reader to other literature in the bibliography. Here we note several serious omissions. E. Fischer's name occurs in the text on p. 82 but none of his papers is listed at the end of the book. At the University of Oslo, Prof. Hjort, collaborating with Drs. Ottstad and Klem, has made a mathematical analysis of yeast growth as a model of increase in population and applied this and similar results to study the fluctuating population of the whale. These three Norwegian scientists have published excellent "Essays on Population" in 1933 but no reference is made anywhere to thei work. Influenced by the application of mathematics to the study of insect epidemics, H. E. Prof. Escherich, the present Rector of the Munich University, has explained "The New Aspect of Forest Entomology", in *Forstwiss. Cen.*, 1930, Heft 12; while from his Institute Prof. Zwölfer has published several classical papers, among others a mathematical essay entitled, "The Theory of Insect Epidemics", *Biol. Zentr.*, 1930, Bd. **50**, Heft 12. These papers also appear conspicuous by their absence. Like most French books the publication under review is an inexpensive one and Messrs. Hermann & Co. have the readers' thanks at the fine get-up and the absence of all errata.

S. M.

The Structure of Metallic Coatings, Films and Surfaces.*

THE papers read at a symposium on this subject conducted by the Faraday Society and the discussions thereon appear in a special number of the *Transactions of the Faraday Society*. A number of well-known workers in this field have taken part and in all there are about thirty papers.

In Part I, Professor Finch and his collaborators have given a complete account of the study of surfaces by electron diffraction methods. Their paper surves as a valuable monograph for workers in this field. It is made quite clear that although there are still a few points to be cleared regarding the interpretation of experimental results, the method of electron-diffraction is probably the most powerful available for the study of surfaces. The evidence given by this method towards the clarification of the "vexed question" of the Beilby layer on polished surfaces is in favour of the existence of such a layer. In the general discussion on this problem Professor Kirchner makes the observation that diffuse bands of the type given by polished surfaces can also be obtained by reflection from suitably prepared, sputtered or evaporated films which however give sharply defined rings by transmission. But sputtered or evaporated films and the polished layer are two different things which are not directly comparable, and thus the evidence against the existence of the Beilby layer is not overwhelming. Hopkins finds that the Beilby layer is about 30 Å thick while Zees finds a layer of oriented crystals separating the Beilby layer from the polycrystalline layer underneath.

In the second part there is a very interesting paper by Professor Andrade, incorporating some remarkable results obtained by him recently. He has followed various stages in the growth of crystals in thin films of silver on heat treatment, by microscopic methods. Spherulites, *i.e.*, uniaxial crystal fibres radiating from a centre, are first formed on heating such films. These gradually grow into single crystals with their 111 planes parallel to the surface of deposition, on increasing the temperature. This observation is in agreement with the results obtained by previous workers by X-ray and electron-diffraction methods as to orientation of crystallites in metallic films on heat treatment.

The remaining papers deal with metallic coatings obtained by electro-deposition, hot dipping and spraying. Macnaughton and others present the results of a study of the hardness of electro-deposited nickel in relation to grain size, *p*H value of the electrolyte, etc. Blum and Kasper find that deposits obtained with nickel chloride solution are fine-grained and relatively smooth, strong, hard and brittle. Those obtained with sulphate baths are rough, coarse-grained, soft and ductile. Professor Kohlschütter's paper on "Somatoids" is valuable in understanding the formation of abnormal growths on the cathode during electro-deposition. Hothersall has studied the influence of the substrate on the structure of metallic coatings obtained by electro-deposition. Wood has made a thorough study of the differences between electrically-deposited metallic coatings and the normal metal by X-ray methods. He finds a broadening of the lines in the X-ray diffraction pattern of such deposits of nickel and chromium and points out a correspondence between this line broadening and the hardness of the deposit. He also finds that the brightness of the deposit was greater in the deposits showing more perfect orientation of the crystallites than in others.

The papers and the discussions which follow them provide a more or less complete survey of the subject. The discussions especially are highly stimulating and in them several interesting points are raised which may form subjects for further work. It is clear from a study of these that the method of electron-diffraction is invaluable for the examination of the structure of surface layers. But other methods involving the use of X-rays, optical properties of the surfaces and microscopic studies are also essential.

* *Transactions of the Faraday Society*, 1935, **31**, Part 9*a*.

1705-35.—Printed at The Bangalore Press, Bangalore City, by T. Subramania Aiyar, Superintendent, and Published by B. N. Sastri, M.Sc., A.I.C., A.I.I.Sc., for the "Current Science" Board of Editors, Indian Institute of Science, Hebbal Post, Bangalore.

Current Science

Vol. IV] NOVEMBER 1935 [No. 5

CONTENTS.

Over-Population in India.

IN an extensive note recently published in the press, the Public Health Commissioner with the Government of India was reported to be contemplating a discussion of the problem of over-population in India in an article about to appear in the *Indian Medical Gazette*, and also as making a suggestion, that the Federal Administration should deal with the issue of family limitation as a remedy for combating the baleful consequences, resulting from an uncontrollable increase of population. In many provinces large masses are at the level of bare subsistence, with hardly any clothing or house furnishings but possessing quite a remarkable power of fecundity. Few will fail to be impressed by the prevailing misery, squalor and poverty of the Indian people, and among the numerous public matters with which the Government of India will shortly be confronted, the subject of raising the economic level of the country and of improving the standard of living of the common people must necessarily occupy the foremost place.

Modern civilisation is full of paradoxes. In the midst of plenty people are allowed to suffer. The banks are embarrassed by a plethora of money, but are unable to release the funds for providing relief to the unemployed. Gold always regarded as an incorruptible standard of currency, has been deflected from its appointed task, with the inevitable effects of discouragement and arrest of business involving human unhappiness. Increase of population considered a sign of public prosperity in the past, has now become a menace. These strange and alarming phenomena in human affairs must inevitably puzzle the ingenuity of all Governments, and perturb the hearts of public leaders. It seems to us that at the root of all these troubles lies the currency problem. The recent policy of sovereign governments of hoarding gold and silver is obviously due to the apprehension of a shrinkage in their supply, and their immobilisation paralyses trade and increases unemployment. If the world would adopt a form of currency, incapable of maldistribution or of being cornered, which could be used purely as a counter or a cheque between services and commodities, perhaps the other social problems might admit of easy solution. It is the inefficient system of world economics that has made some of the existing population superfluous, and the

remedies suggested for restricting the increase are in the nature of an experiment in human biology.

We know that the humanitarian measures, which governments and voluntary public services have adopted for the promotion of the peoples' health and happiness, provided also the causes leading to an absolute increase of population. But no one can seriously suggest the suspension or repeal of all attempts at sanitation and the prevention of disease, the provision of famine relief measures or the protection of the person and property of the people as one of the remedies for over-population. It may be possible to absorb the superfluous population by an extension of irrigation, improved methods of agriculture, emigration and closer settlement of sparsely inhabited lands and by developments in industry and commerce. The limits of what can be done in these directions must be reached sooner or later, and possibly in most parts of the world they must have been already reached. It is legitimate therefore for public leaders to suggest the popularisation of contraceptive technique as an infallible remedy for limiting the number of births, and every child knows that population of manageable dimensions can have more food, better accommodation, higher expectation of life and greater facilities for racial improvement.

Scientists may soon be in a position to estimate exactly what human population India can carry at a tolerable level of existence, providing for freedom, happiness and all the richness and variety implied in a full and complete life. Till we get an idea of the estimated maximum population, the term over-population must continue to be used as a vague one, for reckonings based on insufficient assumptions can have very little practical value. It has to be borne in mind that the numbers of human population alone do not press steadily on the means of subsistence, a large percentage of which being destroyed by other species of animals. Further a large quantity of food good enough for human mouths goes to support stray animals and domestic pets, apart from what is thrown away as waste. We can fairly comprehend the total volume of food consumed by the larger mammals, rodents, birds and insects in the wild state, and by other animals which hang on the outskirts of society rendering little service. We practically ignore the loss of food due to animal depredations when we describe over-population as signifying that in a given area at a given time there are more people than the produce of land can support in a reasonably comfortable existence. We are not pointing to this source of loss as an argument against the suggested remedies for controlling over-population, and we are fairly certain that all the forces arrayed against the general practice of contraceptive methods will be utterly futile to check its progress, for the knowledge relates to an imperious biological process, which interests mankind more than food. In any sphere of human thought and action, freedom without responsibilities is dearly coveted by every one, and critics of birth control point out that the doctrine of the Malthusian League favours such freedom. They desire to know whether the dissociation of freedom and its attached responsibility in society will favour its refinement and ennoble its conscience, where such alienation in the political sphere is apprehended to lead to anarchy. They ask whether the effect which the cause is prevented from producing, will not manifest itself in some other form, or whether in Nature or in the human system, an act can be perpetrated without entailing appropriate consequences. No doubt the advocates of birth control must have thought about such questions and must have satisfied themselves that the practice, which they seek to popularise, is not limited to the single problem of food, but that it really embraces all the aspects and spheres of human existence.

The population of India is about 19 per cent. of the total population of the world, and the rate of increment from 1872 has been 23·2, 13·2, 2·5, 7·1, 1·2 and 10·6 per cent. The actual increase, according to the latest Census Report, since 1921 is 33,895,293 which represents 10·6 per cent. at the last census, and more than 39 per cent. on the population of India fifty years ago, and an increase of 12 persons per square mile in 50 years, during which time the increase in area has been principally, if not entirely, confined to comparatively thinly-populated areas, amounting to 426,055 square miles. During this period the birth rates of various European countries have fallen, England and Wales 36·3 to 17·8; Germany 40·9 to 20·7; Italy 39·2 to 27·8 and Sweden 30·8 to 16·9. There are many interesting subtleties regarding the statistics of population, and according to the computations of American authorities the total optimum population of the world is

lions, which is less than the population India. The optimum population of any intry must depend largely on the standard life, and as there is every need for sing this standard in India, it is obvious it its present population is far above the imum. India is passing through the ning phase of rapid multiplication, tered by modern industrialism such as urred in the European countries from first appearance of factory manufacture the eighteenth century upto the seventies the nineteenth. Indian leaders are of nion that her prosperity depends upon lustrial expansion more than on her icultural pursuits, and that the country ould cease sooner or later to import foreign nufactured articles. This decision inves the reproducing in all factory centres identical conditions which led in the ropean countries to the enormous increase their population. We have to add to h conditions the elimination of all natural eks upon the numbers of a less organised nmunity with little education and a poor ndard of living. The minds of people not troubled by what is known as the oid multiplication of the unfit and by their n relative poverty. The message of birthtrol is a far cry to them, and their education and religious principles have not sufficntly fortified their minds to practise stinence and self-control. Judged by gross conditions in which the poorer nmunities live, a further increase in the al population of India seems inevitable.

Recent authors on the population problem India have drawn attention primarily to question of food production. The gument is that the population of India is eady living permanently on the verge of rcity, and any addition is bound to result an insufficiency of the food supply. The vocates of birth-control emphasise that men who bear numerous children are bjected to miseries, that they lose their serve vitality, and that the children are dernourished and are indifferently eduted. We are not dealing here with the question of maximum population possible in India, t with the other question of maximum pulation desirable, and in this connection is essential to have an accurate estimate the degree to which the recent rise in mber has taxed the ability of the country support its occupants at a reasonable stanrd of living. The position of the econosts in the European countries now appears to be that even if the low birth rate is reversed to former proportions, the rapid development that is taking place in the world production of food would be adequate to meet any such increase. It is doubtful whether, within the next decade, the production of food in India, in spite of rapid researches in the mechanical and biological fields of agricultural occupations, will be sufficient to cope with the increasing numbers. Nevertheless it is reasonable to suppose that the general adoption of improved and intensive methods of cultivation might result in an increased output of at least 30 per cent. throughout India. If in the total cultivable area the process of raising crops was brought under scientific control, and if by any chance the present population of India was not allowed to increase, there can be little doubt that the standard of living of the masses would rise rapidly. But the apprehension is that the population shows a tendency to multiply, unless the law which governs increase is artificially suspended. Is this apprehension based on any scientific theory?

Those who have investigated the population problem point out that this inevitable increase need not necessarily bring misery in its train, since "the orderly evolution of human knowledge justifies us in assuming that science will keep pace in discovering means of expanding opportunities of happy human existence", and the human organism is endowed with the power of adapting itself to an extent not yet imagined. Even if the existence of any community is threatened by an uncontrollable multiplication of its numbers beyond the means of subsistence, Nature has sufficient reserves in maintaining the balance by governing the ratio of fertility unassisted by any extraneous intervention. That Nature has not relinquished her laws of maintaining a definite relation between the maximum desirable population and the means of subsistence is illustrated in the case of the Arab population of Algiers, who show both a decrease in the birth rate, which could not be ascribed to any voluntary practice of contraceptive technique, and a decrease in the death rate which equally could not be ascribed to improvements in public health measures. Attempts to effect a retardation of the rate of increase by voluntary limitation of the birth rate because of the diminution of returns from the land require closer investigation, before any scientific conclusions can be formulated.

The second argument that repeated child bearing involves misery to one section of the Indian population which, it is only human to relieve, is a powerful one, and apparently justifies the wide-spread practice of family limitation by artificial methods. In one of her recent papers published in India, Dr. Marie Stopes has pointed out that the apparatus required by the general masses will cost practically nothing and the means of prevention of conception are available in the poorest houses. The argument that man lives in an artificial society, and that his productivity must be governed by artificial means is generally acceptable, but his bodily functions remain natural and obey the simple laws of metabolism. He retains sufficient plasticity to be affected by the environment he has created for himself. It is well known that the researches of American authors on the reproduction rates of social groups have produced evidence of a negative relationship between educational advance and fertility; further it is almost a demonstrable fact that full-time paid occupations of women are found incompatible with effective reproduction in any large community. Unhealthy crowding in slums seems to raise fertility, but the rural developments which the Government of India and provincial authorities have inaugurated with the object of ensuring decent environment and attractive housing for the poorer classes, and the campaign against congested areas in populous towns must counteract forces conducive to high fertility among families least equipped for this responsibility.

We are not arguing against the new doctrine of family limitation. Its object is, however, gradually realised by the operation of those social phenomena which we have noticed. It is established by the American school of investigators with a fair measure of probability that education, occupation, better housing and a higher standard of life have individually the power of affecting more or less permanently the rate of fertility. The hope of restricting the population of India seems to lie more in the rapid and energetic promotion of those social developments which must inevitably effect fertility rate, than in the promotion of the artificial methods to which sentiment and custom are hard to be reconciled. The results in the latter case are spectacular, but those arising from the former must be progressive and slow.

English as the Common Language of India.

WITHIN the last two months there have been many notable public utterances on this subject. Vernaculars are generally favoured as the medium of instruction, and some of these languages have sufficiently developed to be adopted for this purpose. Urdu is now used in the Osmania University for imparting instruction in all the branches of scientific and humanitarian knowledge, and few will doubt its capacity to galvanise the national intellectual life. Hindi, Bengali and Marathi possess an equally rich literature, and like Urdu they possess all the flexibility and assimilative power of a virile and growing language. The vernacular press, which is an efficient instrument for instructing and interesting the masses in public affairs, has been increasing in large numbers, and, given the proper encouragement, some of them are bound to exercise a great influence on the thoughts and aspirations of the people.

Sir Martin Forster, in his illuminating presidential address delivered during the Education Week Celebrations of the Bangalore Educational ...ociation in the second week of this month, ...ed the following significant sentence from a ... addressed by Babu Rajendra Prasad to the students of Madras. The latter recognised "one great advantage in the English language and English literature which you cannot get elsewhere. The English literature is full of the ideals of freedom and liberty which Englishmen have cherished". In the Convocation Address to the Annamalai University which, for breadth of view and clear grasp of the fundamental problems, is really brilliant, Amin-ul-Mulk Sir Mirza Ismail remarked, "To my mind the antithesis (vernacular and English) is both superficial and unnecessary ....English is undoubtedly a most useful language to learn from every point of view,—social, cultural, educational and political,—and no University in India can afford to neglect it." Mr. C. Y. Chintbamani in his Convocation Address to the University of Mysore deprecated the use of English as the common language of India. Sir Mirza Ismail and Sir Martin Forster viewed the problem from a higher standpoint, when they drew attention to the value of the English language, "as a constituent of Indian National efficiency, and its relation to the share that India is destined to assume in the problem of Internationalism."

The Ultracentrifuge and Its Applications.

By The Svedberg.
(*Fysikalisk-Kemiska Institutionen, Upsala.*)

ZSIGMONDY'S monograph "Zur Erkenntnis der Kolloide" which appeared in 1905 is to be looked upon as one of the mile-stones along the road of advance in colloid science. In this book was collected the experimental material showing conclusively that a great number of apparently homogeneous pseudosolutions or colloids are really heterogeneous in nature, being built up of small particles suspended in a liquid. The new means used for carrying out these observations was the ultramicroscope constructed by Siedentopf and Zsigmondy in 1903. By way of analogy it appeared probable that all colloids are similarly built.

The ultramicroscope, however, has two serious limitations. In the first place, it can only make visible particles the index of refraction of which differs greatly from that of the solvent (or dispersion medium, as the "solvent" of colloids is usually called). Only in especially favourable cases, such as gold, platinum and silver particles, is it possible to penetrate down to sizes of the order of $5m\mu$. The wide and important domain of lyophilic colloids, such as sulphur, ferric oxide, silicic acid, proteins, starch, cellulose, rubber, can only to a very limited extent be explored by means of the ultramicroscope. In the second place, it is to be noted that an ultramicroscopic study even in the favourable case of, say, a gold colloid, can only give rather incomplete information with regard to the statistical distribution of the various particle sizes present in the colloid solution.

Zsigmondy's monograph impressed the writer greatly when he, as a young research student, became acquainted with it. Mainly through its influence his studies were directed towards research in colloids. During these activities the limitations of the ultramicroscope became evident to him and he soon found himself engaged in a search for some other means of attack in cases where the ultramicroscope failed. The brilliant work of Perrin (1908) on the Brownian movement and the sedimentation of small particles suggested some method built on diffusion, osmotic pressure and sedimentation. It should be possible, so the writer argued, to combine these properties so as to dispense with the necessity of making the particles visible.

After some preliminary work on diffusion and sedimentation of colloids (1911) and after Odén had carried out in the writer's laboratory his beautiful researches on the size-distribution of particles by means of a self-recording balance (1916) which measured the accumulation during sedimentation in the field of gravity, the writer decided to try the possibility of studying particle-size and size-distribution curves by means of the centrifuge (1922). Earlier attempts in this direction did not seem very encouraging. The first trials made by Nichols and the writer in the chemistry department at Wisconsin (1923) showed, indeed, that this road would not be an easy one to travel along. In the first place, it was evident that all measurements had to be done while the sample was rotating at constant speed. Accordingly only optical methods could be used for recording the sedimentation. In the second place, the centrifuging had to be conducted at constant or only slightly and uniformly varying temperature. These two conditions have to be fulfilled in order to obtain convection-free sedimentation. In the third place, the centrifugal field created within the solution to be studied should be of high intensity and homogeneity.

The conditions for convection-free sedimentation were studied by Rinde and the writer (1924) using fine-grained gold sols as test objects. It was found that the sample must be sector-shaped, completely enclosed and of not too large dimensions. The friction against the surrounding gas has to be reduced and the heat from the bearings kept away. We found it possible to perform faultless sedimentation in centrifugal fields 5,000 times the force of gravity (mean radius 45 mm., height of column of solution 15 mm., speed 10,000 r.p.m.) and to measure the size-distribution in gold sols down to the most fine-grained ones. The name ultracentrifuge was proposed for this new research tool.

Using the same apparatus Fåhræus and the writer (1925) succeeded in determining the molecular weight of proteins by means of sedimentation measurements. Evidently the ultracentrifuge would be of great value

as a research instrument in the study of high-molecular compounds. Feeling convinced of this the writer decided to do his best to develop further the ultracentrifuge idea.

In 1926 F. Ljungström, A. Lysholm and the writer reached 100,000 times gravity (mean radius 52 mm., height of column of solution 12 mm., speed 45,000 r.p.m.). In the spring of 1931, further improvements of the machinery accomplished by G. Boestad and the writer made possible sedimentation measurements at 200,000 times gravity (or 200,000 g.), (mean radius 65 mm., height of column of solution 12 mm., speed 54,000 r.p.m.). Using the same radius and the same height of column of solution we reached 260,000 g. early in 1932, 300,000 g. in the spring of 1932 and 400,000 g. in the spring of 1933.

measurements made in very intense centrifugal fields using a low column of solution and a small mean radius with such made in somewhat less intense fields using a higher sample situated farther from the centre of rotation has shown that the accuracy is much better in the latter case at least as far as sedimentation velocity measurements are concerned. For a standard equipment, therefore, a large rotor is to be preferred.

From the many different experimental machines built in Upsala two standard types have been developed. The first one is adapted for the region 500 to 15,000 g., the other one for the range 15,000 to 750,000 g. The low-speed machine is driven directly by a high-frequency motor and is provided with ball-bearings. The rotation takes place in hydrogen of atmospheric pressure and the casing is immersed in a

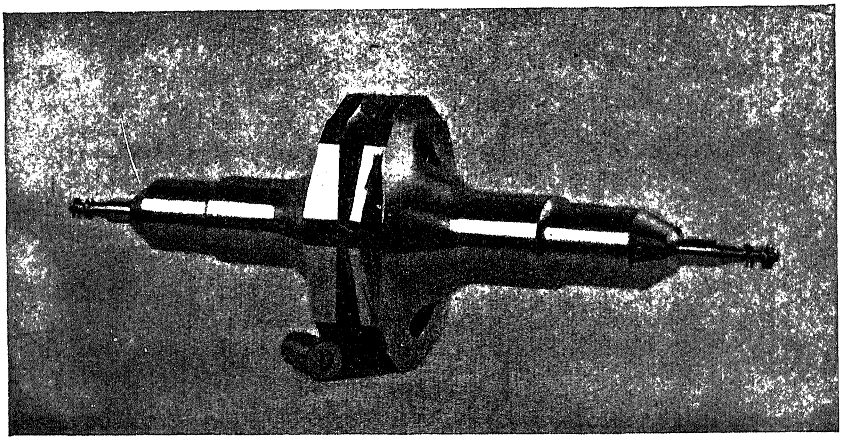

Fig. 1.

Rotor and cell for centrifugal fields up to 750,000 times the force of gravity.

Essentially higher fields cannot be utilised with rotors of this size because of failure of the material. It seemed of interest to try a smaller rotor type capable of giving considerably higher intensities although at the sacrifice of height of column of solution and homogeneity of the centrifugal field. Reducing the mean radius to 36 mm. and the height of sample to 8 mm. sedimentation measurements in fields up to 600,000 g. were made in the autumn of 1933 and up to 900,000 g. in the summer of 1934. The rotors used in these experiments exploded however after a few runs. A further reduction of the mean radius to 32·5 mm. and improvements in the construction have made it possible to do regular measurements in fields up to 750,000 g. The comparison of

water thermostat. It is used for sedimentation equilibrium measurements in solutions of high molecular substances and for sedimentation velocity measurements on heavy particles.

The high-speed machine is driven by oil-turbines and has white-metal bearings with movable, damped pistons. The rotor spins in hydrogen of reduced pressure. It is used for velocity measurements in solutions of high-molecular compounds and for equilibrium measurements on low molecular substances.

A few details concerning the oil-turbine ultracentrifuge might be of interest. The rotor (Fig. 1 and 2R) of chromium-nickel steel is supported by horizontal bearings, B_1 and B_2 (Fig. 2), and kept in rotation by

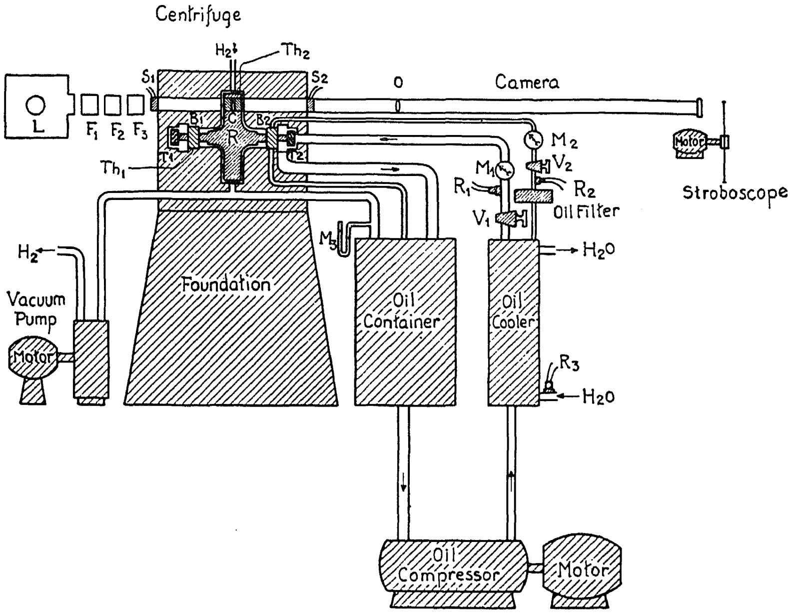

Fig. 2.

Diagrammatic representation of the oil-turbine ultracentrifuge.

means of two small oil-turbines, T_1 and T_2, one on each end of the shaft. Hydrogen is let in at the periphery and constantly pumped off so as to maintain a pressure of about 25 mm. Thermocouples, Th_1 and Th_2, in the bearings and at the inner surface of the heavy steel casing, which surrounds the rotor, serve for temperature control of the centrifuge. A beam of light from a mercury lamp L, filtered through F_1, F_2, F_3, passes the cell C in the rotor on its way to the camera. The exposures are timed by means of the electromagnetic shutters S_1 and S_2. A stroboscope enables the observer to measure the speed of the rotor. The pressure oil which feeds the turbines is produced by a special oil compressor and cooled to a suitable temperature before entering the turbine chambers. The lubricating oil for the bearings passes through an oil filter and is controlled by the valve V_2. By changing the speed of the motor which drives the compressor and by operating the valve V_1 the pressure of the oil entering the turbines may be regulated so as to make possible sedimentation measurements at any desired speed between 5,000 and 140,000 r.p.m. The resistance thermometers R_1, R_2, R_3 and the manometers M_1, M_2, M_3 enable the operator to control temperature and pressure in various parts of the machinery.

A detail section of the centrifuge proper through the axis of rotation (with a previous

Axial section of the oil-turbine ultracentrifuge.

type of rotor) is given in Fig. 3. Fig. 4 shows a picture of it with the upper part of the heavy steel casing lifted, laying bare the rotor and the turbine chambers. The cell with its sector diaphragm is in vertical position upside down. Behind the centrifuge is the lamp house and the light filters. The two halves of the thick steel casing are held together by bolts of chromium-nickel steel firmly anchored in a concrete

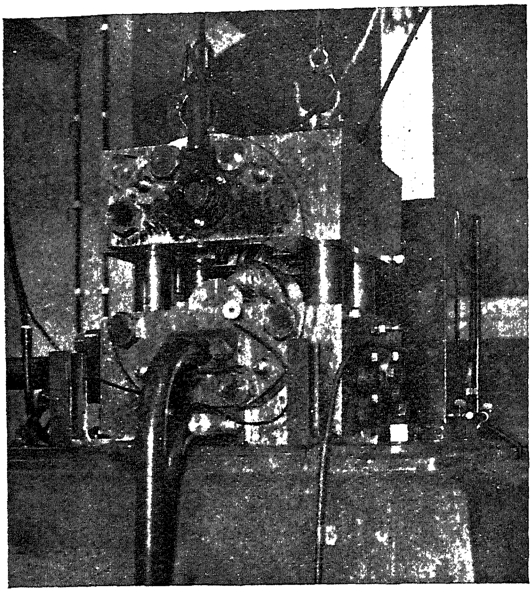

Fig. 4.

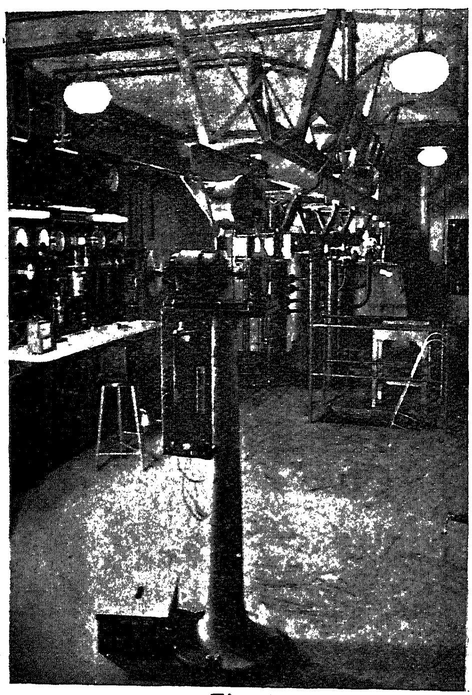

Fig. 5.
Oil-turbine ultracentrifuge installation.

foundation. This arrangement has proved an efficient protection in case of accident (explosion of the rotor caused by overstrain). Fig. 5 gives a total view of the installation showing the stroboscope for measuring the speed, the camera, the centrifuge on its foundation, the oil coolers and, to the left, the switchboard with all the control instruments.

Two kinds of measurements can be done by means of the ultracentrifuge. In the first place, one may centrifuge long enough for a state of equilibrium to be reached between sedimentation and diffusion. Then for each molecular (or particle) species the following formula is valid:

$$M = \frac{2\,RT\,ln\ (c_2/c_1)}{(1-V\rho)\omega^2(x_2{}^2-x_1{}^2)}$$

where M = molecular (or particle) weight, R = gas constant, T = absolute temperature, c = concentration of solute, V = partial specific volume of solute, ρ = density of solvent, x = distance from centre of rotation, ω = angular velocity.

In this way one obtains directly the molecular weight. If several molecular species are present in the solution the molecular weight values calculated for different distances from the centre of rotation show a marked drift. Freedom from drift is a criterion of homogeneity with regard to molecular weight.

In the second place one may use a centrifugal field strong enough to cause the molecules or particles to sediment with measurable velocity. This procedure enables

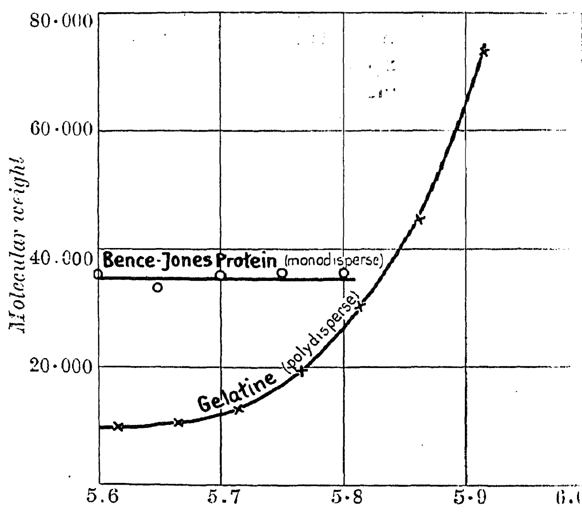

Fig. 6.
Sedimentation equilibrium of Bence-Jones protein (monodisperse) and gelatine (polydisperse).
(B. Sgögren and K. Krishnamurti)

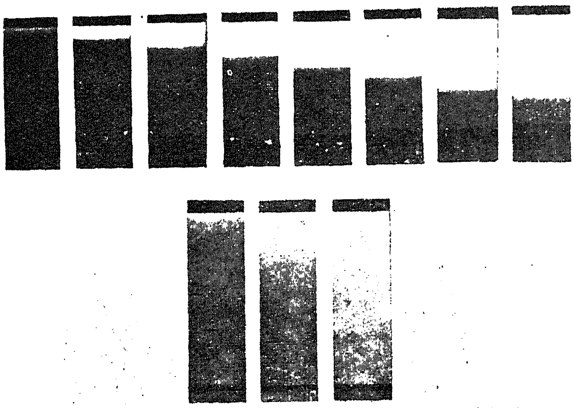

Fig. 7.

Sedimentation of hemocyanin (upper row) and gold colloid (lower row) in a centrifugal field 37,000 times the force of gravity; time between exposures 3 minutes. The former is monodisperse, the latter polydisperse. (E. Chirncaga and H. Rinde)

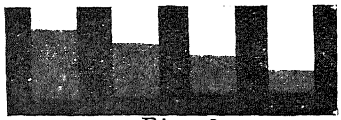

Fig. 8.

Sedimentation of hemoglobin in a centrifugal field 900,000 times the force of gravity; time between exposures 3 minutes. (Inga-Britta Eriksson-Quensel)

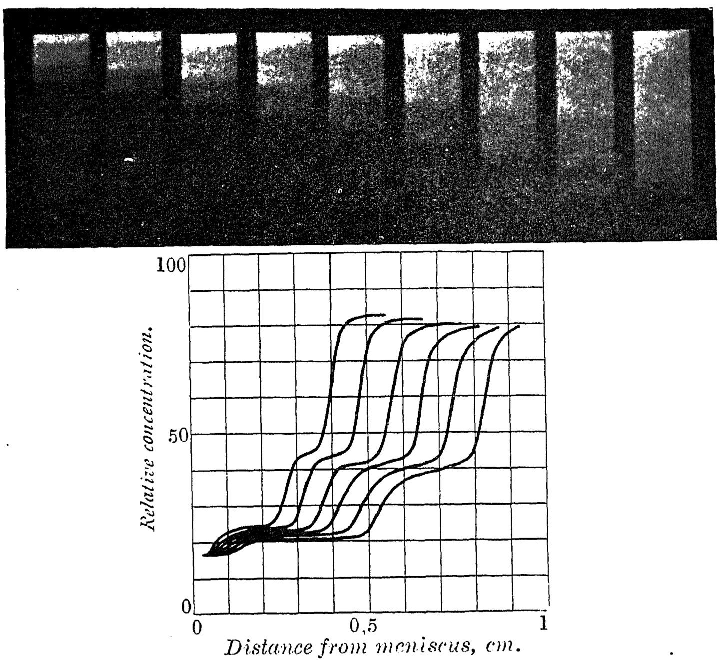

Fig. 9.

Sedimentation analysis of Helix-hemocyanin at the alkaline border of the stability region. Centrifugal field 33,000 g.; time between exposures 5 minutes. (K. O. Pederson)

us to find how many different kinds of molecules are present in the solution. If the sedimentation velocity is referred to unit field and water of 20° C. as solvent, it is called the sedimentation constant. By combining diffusion and sedimentation data the weight of the different molecular species may be calculated according to the formula

$$M = \frac{RTs}{D(1-V\rho)}$$

where s = sedimentation constant, D = diffusion constant.

Sedimentation measurements in the ultracentrifuge may also be used for the determination of the weight-distribution or size-distribution of molecules or particles in a polydisperse mixture. The theory being rather complicated we will not go into it on this occasion.

ii.

The ultracentrifuge has a wide range of

application. With the aid of this tool molecular weight determinations have been done from about 10,000,000 (hemocyanin-variety in the blood of the snail Busycon) down to about 40 (lithium chloride). Quite unique is the possibility which this technique offers of carrying out an analysis of the various molecular species or particle sizes present in a solution. The sedimentation constant is a very characteristic molecular

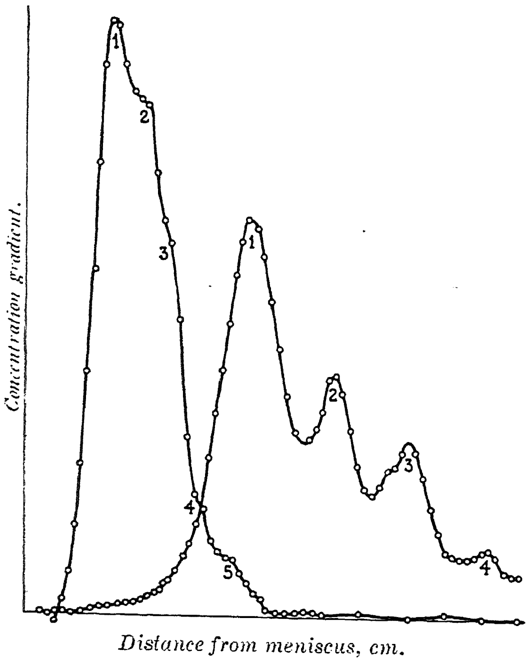

Fig. 10.

property and by means of it, one often finds it possible to follow sensitive aggregation- and dissociation-reactions in biological systems. The combination of sedimentation equilibrium and sedimentation velocity measurements allows of certain conclusions with regard to the shape of the molecules or particles. This is often of importance when investigating high-molecular compounds.

Among the substances studied so far are proteins, polysaccharides, poly-styrols, dye-stuffs and other synthetic organic compounds as well as inorganic colloids and inorganic salts.

Some of the main results of the protein investigations may be mentioned. The native proteins are very homogeneous with regard to molecular weight while artificial colloids as well as proteins extracted from the organisms by rough treatment are poly-disperse. As an example of a homogeneity test by means of sedimentation equilibrium measurements the diagram Fig. 6 gives the values of the molecular weight as measured at different distances from the centre

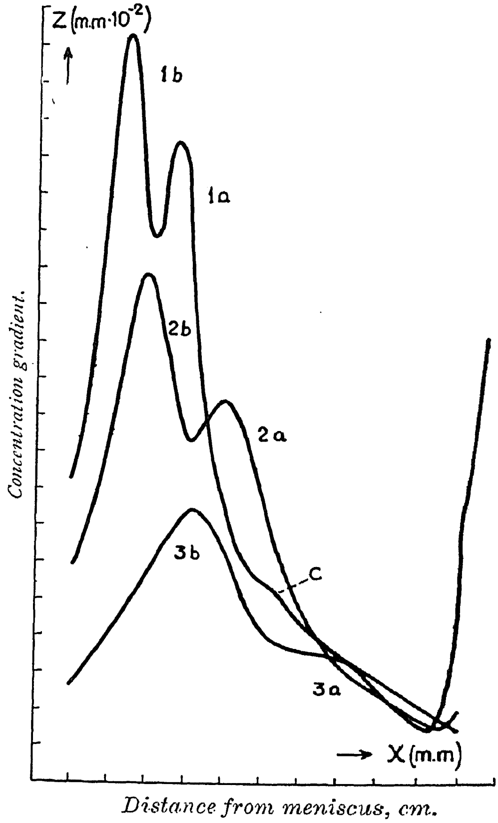

Fig. 11.

Refractometric sedimentation diagram of a solution of starch treated with acid, centrifugal force 145,000 g. (O. Lamm)

of rotation in the case of a homogeneous substance, Bence-Jones protein (B. Sgögren) and an inhomogeneous substance, gelatine (K. Krishnamurti). This is further demonstrated by the sedimentation velocity runs in Fig. 7 which shows in the upper row (E. Chirnoaga) the sedimentation of hemocyanin from the blood of Helix (M = 6,600,000) and in the lower (H. Rinde) the sedimentation of a gold colloid, both of them in a centrifugal field 37,000 g. In the first case the border-line between solution and solvent remains sharp, in the second case it becomes blurred with time because of the different speed with which the gold particles of different sizes are sedimenting. To test the homo-

geneity of a substance of lower molecular weight by a velocity run the centrifugal force has to be increased so as to get sufficient sedimentation before a blurring of the boundary by diffusion takes place. Fig. 8 shows the sedimentation of hemoglobin (M = 69,000) in a centrifugal field 900,000 times the force of gravity (Inga-Britta Eriksson-Quensel). The border-line remains sharp and the protein in question is, accordingly, quite homogeneous.

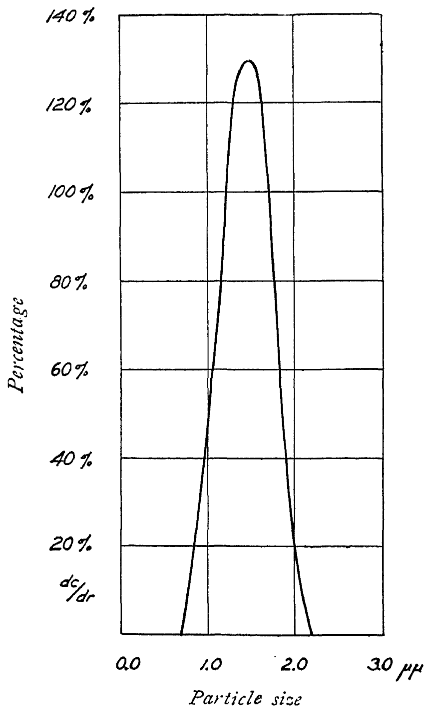

Fig. 12.
Size-distribution in a gold colloid.
(H. Rinde)

The molecular homogeneity of a protein remains unchanged when the pH of the solution is changed within certain limits. At well-defined pH-values changes in the shape or in the weight of the protein molecule take place. Among the hemocyanins a number of reversible dissociation-association reactions have been observed. As an example the behaviour of Helix-hemocyanin at the alkaline stability border may be given. Fig. 9 (K. O. Pedersen) shows the presence of two dissociation products of mass $\frac{1}{2}$ and $\frac{1}{8}$ together with unchanged molecules. A closer study of this phenomenon reveals the fact that the hemocyanin-molecule is at first split into halves and some of these halves into four parts (Inga-Britta Eriksson-Quensel).

In some cases the association state of a protein is dependent on the dilution and on the presence of other proteins. Recent investigations on serum have shown (A. S. McFarlane) that the globulin may appear in molecules of different mass according to the concentration of the albumin present in the serum. Pathological states of the organism bring about characteristic changes in the sedimentation diagram of the serum proteins (Fig. 10), a fact that suggests the use of the ultracentrifuge as a possible instrument for diagnostic purposes.

An ultracentrifugal study of solutions of starch (O. Lamm) has given the following result. Depending on the previous treatment the particle size varies, but always in a continuous way. No distinct molecular species were found. Preparations treated with acid show two maxima corresponding to amylose and amylopectin (Fig. 11). A detailed investigation of the solutions of poly-styrols in various organic solvents has been carried out (R. Signer). The molecules were found to be very elongated and free movement was observed only in very dilute solutions. The viscosity increases with molecular weight. Gold colloids were among the first objects of ultracentrifugal investigations. Fig. 12 shows the size-distribution curve of a very fine-grained gold sol (H. Rinde).

iii.

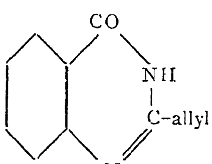
The utilisation of the ultracentrifuge for the study of high molecular compounds is only at its beginning. As research goes on new problems present themselves for treatment with this new tool. So far the main interest of applications has been in the field of biology and medicine because of the various kinds of new information which the ultracentrifuge has made available with regard to the behaviour of the proteins—those substances of paramount importance to all living beings. But there are also the vast fields of the carbohydrates, the hydrocarbons and the synthetic organic high-molecular compounds. A number of important chemical industries are handling materials belonging to one or the other of these classes of substances. The research laboratories connected with such industries are beginning to realise that the ultracentrifuge may be able to render services of great value in elucidating the properties of the molecules and particles which are the building-stones of cellulose, artificial silk, varnishes, rubber, dyes and many other products,

Vasicine.

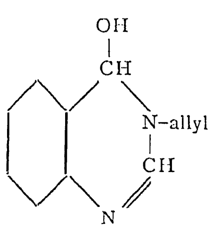
By K. S. Narang and J. N. Ray.
(University Chemical Laboratories, The University of the Panjab, Lahore.)

VASICINE, $C_{11}H_{12}ON_2$, an alkaloid, was isolated from the leaves of *Adhatoda Vasica*, Ness by Sen and Ghosh.[1] It was found to be a monacid base and further studies by Ghosh[2] revealed the presence of a quinazoline ring. With phosphorous penta-chloride, it was converted into chloro-desoxy vasicine indicating that a hydroxy group replaceable by chlorine exists in the molecule. With alkaline permanganate it gave a substance believed to be 4-oxyquinazoline but direct proof of its formation was furnished by Ghosh, Krishna, Narang and Ray.[3] Ghosh[2] was of the opinion that vasicine was 2-propyl 4-oxyquinazoline, a substance which was later on synthesised by De and Ray[4] and proved to be not identical with vasicine. Ghosh, Krishna, Narang and Ray[3] found evidence that vasicine is converted into an isomeric substance by traces of alkali and gave a solid acetyl derivative. But Narang and Ray[5] were of opinion that the isomeric base may be impure vasicine.

In 1934, Späth and Nikawitz[6] were supplied by the firm of E. Merck, a base isolated from the mother liquors of *peganam harmala*. This base melted at a slightly higher temperature because the m.p. was determined *in vacuo*. Its formula was $C_{11}H_{12}ON_2$ but it gave a liquid acetyl derivative and hence the question of its identity with vasicine was left open by these authors. Oxidation with permanganate furnished 4-oxy-quinazoline 3-acetic acid and hence the formula II was advanced by Späth and Nikawitz as



I



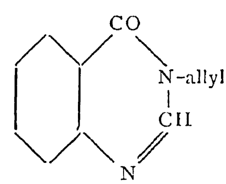
II

against (I) advanced sometime ago for vasicine by Ghosh, Krishna, Narang and Ray.[3] The solubility of vasicine in acetone also differed from the solubility of peganine in the same solvent. Hanford, Liang and Adams[10] showed the solubility of vasicine in acetone to be small as observed by Ghosh, Krishna, Narang and Ray[3] and the greater solubility of peganine must be due to associated impurities.

Narang and Ray[5] criticised the Späth-Nikawitz formula on various grounds and expressed the opinion that vasicine may not after all be identical with peganine because the acetyl derivative has been found by Späth and Nikawitz[6] to be an oil as against the solid dehydro acetyl derivative of Ghosh, Krishna, Narang and Ray.[3]

Späth and Kuffner[7] however definitely established the identity of vasicine and peganine. Reynolds and Robinson[8] suggested that in view of identity of vasicine and peganine, the latter name is redundant. These authors[8] conclusively proved the Späth-Nikawitz formula to be incorrect by synthesising a substance of the structure II by an unambiguous method. Narang and Ray[9] advanced additional evidence against formula II proposed by Späth and Nikawitz.

Narang and Ray[5] synthesised the compound III and proved that its reduction product with sodium and amyl alcohol was not identical with the similar reduction product of vasicine and hence the structure II advocated by Späth and Nikawitz was untenable. In this connection it must be stated that Späth obtained a base $C_{11}H_{16}N_2$ by the reduction of vasicine. It is impossible to get a substance of that formula from vasicine.



III

Narang and Ray[9] then proposed two formulæ—one a cyclic system of three rings and another, an open chain—for vasicine. If the open chain one was the correct representation of vasicine, then in oxidation and other

reactions it passed through an intermediate tricyclic stage. They further pointed out that desoxy-vasicine was not identical with 3-allyl 3 : 4 dihydroquinazoline as would be the case if formula II of Späth and Nikawitz was the correct structure of vasicine. Hanford, Liang and Adams,[10] besides supporting Narang and Ray,[9] advanced the additional argument that 3-allyl 4-keto 3 : 4 dihydroquinazoline can be catalytically reduced, whilst vasicine is unaffected. They advanced a cyclic formula for vasicine which is much nearer the truth than the set of random suggestions of Späth and Nikawitz.[6] Moreover the position of the hydroxyl was taken to be in β-position in the third ring whilst actually it is in α-position. It must be stated that Späth and Nikawitz only suggested in their paper all possible variations in which $C_{11}H_{12}ON_2$ can be arranged as a quinazoline and it is not fair to attribute to them the formula that later on was proved to be correct.

Narang and Ray[11] prepared IV and V and found that the electrolytic reduction product of IV was not identical with the similar product from vasicine but the reduction product of V was identical with the reduction product of vasicine. Hence vasicine has a linear cyclic formula. Späth, Kuffner and Platzer[12] synthesised desoxy vasicine from *o*-nitro-benzylamino butyric acid which, on reduction and treatment with phosphoryl chloride, passed into a substance which, on reduction with sodium and amyl alcohol, furnished a product identical with the reduction product of desoxy vasicine. This product is identical with the reduction product of V. Neither the work of Späth, Kuffner and Platzer[12] nor that of Narang and Ray[11] furnishes any proof of the position of the hydroxy group. But Morris, Hanford and Adams[13] furnish an acceptable evidence of the position of the alcoholic hydroxyl group.

Finally *o*-nitrobenzyl chloride on condensation with α-hydroxy-γ-aminobutyrate furnished a product which was cyclised, after reduction to a substance identical with vasicine, by Späth, Kuffner and Platzer[14] and hence vasicine becomes VI. It will be seen that the hydroxyl group is attached to the α-position and is not in the β-position, where it figures in the various formulæ proposed by Späth and Nikawitz.[6]

Späth, Kuffner and Platzer[15] now find that vasicine gives a solid acetyl (dehydro) as stated by Ghosh, Krishna, Narang and Ray.[3] Narang and Ray[5] based their view of non-identity of vasicine and peganine on Späth's reporting the acetyl derivative to be a liquid.

Späth, Kuffner and Platzer[16] have resolved vasicine into optical enantromorphs but since natural vasicine is a *dl* compound, this paper has no bearing on the constitution of vasicine. But Ghosh, Krishna, Narang and Ray have already stated that vasicine is resolvable, a fact which Späth, Kuffner and Platzer have acknowledged.

A Ram Sarcophagus from Cuddapah.

By M. D. Raghavan, M.A., *Government Museum, Madras.*

THE terra-cotta sarcophagus illustrated was unearthed at Sankavaram, a small village about two miles north of the town of Porumamilla, in February 1935, in the Badvel Taluk of Cuddapah District, in the course of digging for the foundations of a new church. The discovery was brought to the notice of the authorities of the Madras Museum by the Bishop of Dornakal. The sarcophagus and the associated pottery were carefully preserved by the parson, Rev. Christudary, at the S.P.G. Parsonage at the adjoining village of Markapuram, until I took charge of them, and removed them to the Museum in May last. The objects were exhibited before a meeting of the Archæological Society of South India at Madras in June, and evoked considerable interest.

The human character of the interment which the sarcophagus contained is not open to doubt as is evident from the skeletal remains. There is no charring of the bones which are so much decayed that they have turned completely white.

The sarcophagus is of unique interest in that it is in the shape of a ram. The ram's head is clearly modelled, the curling horns being emphasised, and the ears omitted. The only other funerary vessel in animal

'nown from South India is a small- 'om the left bank of the Tunga- er, with a rounded body, and ped legs, which suggested to e an elephantoid form.[1] Its head part was, however, not found and in the absence of this part the identification of an elephantoid form cannot be definite.

The trunk of the ram is so modelled that the lower part of it, supported by the legs, forms the receptacle for the bones, and the upper part forms a lid. This upper part is modelled in two pieces, the section in front ending in a well-arched neck, at the apex of which is a wide aperture. About half way from the top a hole is placed symmetrically on either side of this section. The portion of the lid behind is well rounded, and is so modelled as to simulate the hind part of an animal, which only lacks the tail to complete the picture.

Elaborate decoration with impressed rope-work design is a feature of the object, the decoration extending all around the borders, and running longitudinally along the central line of the lid from the neck to the hind quarters. The character of this decoration is suggestive of the trappings of an animal caparisoned for riding.

For the proper understanding of the probable significance of the ram form, we have to take note of the vast complex of ideas associated in the mind of primitive man with the animal kingdom. The domestication of animals fostered a feeling of kinship, and greatly influenced primitive man's attitude towards death. Certain animals came to be regarded as embodiments of the souls of the dead, and the ram often served as one such soul-animal. The sheep was the object of special rites with all pastoral peoples; it entered so much into the life of all early peoples that it was the chosen animal to bear all the sins and evils of mankind as the goat was among the Jews.

With the idea of the ram as a soul-animal, which has the soul of the deceased in its keeping, is possibly linked the idea of its acting as a convoy in transporting the soul to the spirit world, an idea which is suggested by the decorative trappings of the ram as if caparisoned for riding.

Of obvious significance in this connection is the position assigned to the ram in the hierarchy of the gods of early Indian faith.

[1] Bruce Foote, "Indian Pre-historic and Proto historic Antiquities—Notes on their Ages and Distribution," 185-86.

A deity invoked as early as the Rig Vedic times for obtaining a son was Naigamēsha. In the medical treatises, Naigamēsha is, however, a ram-faced demon causing children's diseases. Offerings to the ram-faced god are among the remedies prescribed for such diseases. This association of two opposite ideas—that of a deity dangerous to children, and of a deity helpful in the procreation of children, is interesting.[2] The enclosing of the bones of the deceased within a ram-faced sarcophagus would seem to suggest a request to Naigamēsha to ensure that the deceased might through his influence be born back on earth.

The clay sarcophagus lay at a depth of about 6 feet below ground level. Perhaps the most conspicuous feature of the land is the abundance of rounded pebbles and boulders strewn about the place, indicative of considerable surface denudation. Situated in the slope of the valley formed by the spurs of the Eastern Ghats, the place has apparently witnessed considerable changes in climate. The geology of the country is a matter for further investigation.

The associated finds are two pieces of iron objects—a spear head and a fragment of a knife or sickle—both found inside the sarcophagus highly corroded; and an interesting series of pottery, a squat type of vessel with shield-shaped back, and shallow all-black pans predominating. The pans are highly polished and some bear spiral marking inside.

The ram sarcophagus is also interesting for the evidence it gives of the early domestication of sheep in this part of South India, where sheep farming is still a most flourishing industry.

Diwan Bahadur Sir T. Vijayaraghavacharya.

THE retirement of Diwan Bahadur Sir T. Vijayaraghavacharya on October 25th after a short period of leave, marked the completion of a long and distinguished record of Government service. The Diwan Bahadur was born at Karur in 1875 and entered the Madras Civil Service in 1898 so that he has 37 years of service to his credit. He rapidly made his mark as a district officer and the intimate knowledge of village life then gained has stood him in good stead. His first administrative post was with the Madras City Corporation from 1912 to 1917. After a period as Secretary to the Board of Revenue, which gave him a further insight into revenue administration, he was Diwan of the Cochin State in 1919 till 1922. The Diwan Bahadur first became known to most people in other parts of India as Commissioner for India at the British Empire Exhibition, Wembley—a task which occupied him from 1922 to 1925 and where his great organising ability had full scope. His distinguished services to India and the Empire were appropriately recognised in 1926 when the Knighthood of the Most Excellent Order of the British Empire was conferred upon him by His Majesty. On return to India, he became Director of Industries, Madras, for a short period but was very soon appointed as Member of the Public Service Commission when that body was first constituted. When Sir Vijaya became the first Vice-Chairman of the Imperial Council of Agricultural Research in 1929, he possessed in full measure the qualifications laid down as essential for the Council's principal administrative officer by the Royal Commission on Agriculture. An agriculturist and landowner by birth and tradition with long and varied administrative experience, he was able to appreciate all points of view and displayed great skill in the conduct of debates which were frequently highly technical in character. As a Chairman, his impartiality and never-failing good humour were coupled with the gift of accelerating business. Outside the formal meetings, his relations with all members of the Research Council and his staff were most happy. Not only did he promote co-operation within the Council but he made its aims, objects and work well known throughout India and secured for it a wide measure of unofficial support. During the period of retrenchment and financial stringency, which overtook the Council early in its career, his sustained optimism and constant advocacy of the fundamental importance of agricultural research to the well-being of the Indian nation were invaluable. That the Imperial Council of Agricultural Research has been able to go as far as it has in the direction of fulfilling the intentions of its distinguished

founders is due in no small measure to the personality of its first Vice-Chairman. He did much to bring the Research Council into touch with the Indian Universities. He was an active member of the Indian Science Congress, over the Agricultural Section of which he presided in 1930, and he became a foundation Fellow of the National Institute of Sciences of India on the formation of that body in January 1935. Scientific workers in all subjects found in him a sympathetic and understanding listener. In later years Sir Vijaya was a great traveller. His duties as Commissioner for the Wembley Exhibition took him all over India as well as to England. In 1926 he opened the Canadian National Exhibition at Toronto and gained many friends in that Dominion. In 1930 he led the Indian Delegation at the General Assembly of the International Institute of Agriculture and visited Europe again early in 1932. In the following year he gave evidence before the Joint Parliamentary Committee on the Government of India Bill and he made another flying visit to England and the Continent in 1934. In India he toured freely on the Council's business. The Diwan Bahadur is now enjoying a well-earned holiday in England but has by no means abandoned his interest in Indian agricultural affairs. Fortunately neither the Imperial Council of Agricultural Research, nor the Indian Central Cotton Committee, of which he was Chairman for six years, will lose the benefit of his experience for the Government of India have appointed him, by name, as a member of both these organisations. His many friends in Simla, Delhi and South India can wish him a happy period of retirement in the full knowledge that his active and versatile mind will still be fully occupied for the benefit of his country.

SANDALWOOD—Hawaii's Most Valuable Tree.

SANDALWOOD, theme of a thousand romances and poems of early commerce, is being groomed for a comeback in the forests of Hawaii. It once existed there in great quantities, but over-exploitation 125 years ago by an alliance of traders and native potentates almost wiped it out.

The forests were devastated at that time because of the high prices that could be secured in China for this sweet-scented wood. They promise to be re-established because that price still maintains.

C. S. Judd, territorial forester, some years ago secured from Mysore (India), seeds of what is held to be the most valuable species of sandalwood. He planted these seeds on a ridge in the suburbs of Honolulu and they grew abundantly. To-day there are some 1,500 three-year-old trees on this ridge. They are bearing all the seed that is needed for nursery use. Apart from these, an old sandalwood tree is occasionally found in some remote mountain canyon.

In the pots at the nurseries in Hawaii ironwood seeds are planted with the sandalwood. In its native state the sandalwood always grows among other trees and helps itself to aid from their roots, as a partial parasite. On the ridge that overlooks Honolulu where 1,500 young trees are growing vigorously they stand among lantana bushes, members of the verbena family.

Sandalwood trees grow rather rapidly. They are of some value at the age of 25 years. It is the heart of the tree, however, that is most precious, and heart-wood is not likely to develop greatly until the tree is 40 or 50 years old. Since the present plantings are chiefly in territorial forests, however, the profits do not need to be immediate to make the enterprise sound.

The Raman Spectrum of Crystalline Selenious Acid.

PRINGSHEIM AND YOST[1] studied the Raman effect in an aqueous solution of selenious acid (H_2SeO_3) and recorded two broad and fairly intense lines of frequency shifts 695 and 885 cm^{-1}. I have recently investigated this substance in the form of transparent crystals and obtained a very intense spectrum at an exposure of about four hours which consists of a large number of sharp lines. The photograph of the spectrum is reproduced in Fig. 1. The frequency numbers of these lines in cm.$^{-1}$ are 940 (1), 909 (2), $\overline{888}$ (10), 862 (0), 706 (3), $\overline{597}$ (8), 524 (3), 364 (0), $\overline{299}$ (2), $\overline{287}$ (3), $\overline{254}$ (6) and $\overline{199}$ (3). The numbers within the brackets indicate the relative intensities of these lines and a dash above some of them shows that their anti-stokes are also present. These lines have been obtained with 4046 and 4358 radiations of the mercury arc with equal intensity.

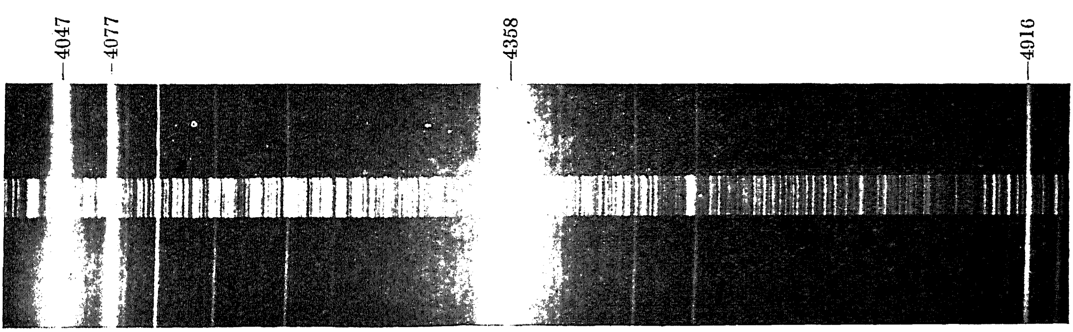

Fig. 1.

The spectrum of the solid is thus markedly different from that of the aqueous solution of this acid and resembles, in its general features, the anomalous behaviour observed by me in the iodic acid.[2] The detailed investigation of this acid as well as the selenic

acid as solid and solutions of different concentrations and their salts is under progress and a full report of the results and their significance in relation to their structure and electrolytic dissociation will appear in the *Proceedings of the Indian Academy of Sciences*.

Determination of the Time of Setting of Gels.

SEVERAL methods have been employed to determine the time required for the setting of a silicic acid gel. Fleming[1] determined it by the criterion that the gel does not flow out of the test tube when it is inverted. Fells and Firth[2] measured it by the maximum pressure required to blow a bubble of air, mercury or chloroform through the gel-forming mixture. Prasad and Hattiangadi[3] noted the intensity of light transmitted through a gel-forming mixture by means of a thermopile connected to a sensitive galvanometer and read the time of setting from the time-deflection curve. Similar methods have been employed by Mardles[4] and by Aritsz.[5] Hurd and Letteron[6] considered the gel to have set when a small glass rod placed at an angle of 15°–20° in the gel-forming mixture remained in position.

Fleming's method has been compared with the optical method by Prasad and Hattiangadi[7] who showed that the time of setting obtained by the former method is less than that obtained by the latter. The results obtained by optical method have now been compared with those obtained by the Bubble and the Rod methods, respectively. It may be mentioned that mechanical devices were employed for the determination of the time of setting by the latter methods in order to disturb the gel-forming mixtures as little as possible.

The gels were prepared by mixing solutions of sodium silicate and hydrochloric acid. The results given in the following Table show that the Bubble method gives the least and the optical method the highest value for the time of setting.

TABLE I.

N	C = 9·8 per cent.			C = 12·1 per cent.		
	I	II	III	I	II	III
0·5	87′-30″	78′-0″	101	137	120	152
0·6	35′-0″	24′-0″	48	39	27	65
0·7	2′-50″	1′-40″	10	3′-15″	2	15

N and C are, respectively, the normality of HCl and the silica content of the gel-forming mixture and I, II and III, the time of setting in minutes by the Rod, Bubble and Optical methods, respectively.

It will be seen that Fleming's, the Rod and the Bubble methods depend upon the attainment of a certain viscosity value, different from each other, by the gel-forming mixture. The observed differences in the time of setting by the Bubble and the Rod methods are due to the fact that greater viscosity is required to prevent a glass rod from falling from a certain position than that needed to prevent the blowing of bubbles of a gas or a liquid, which are very elastic, through the gel-forming mixture.

It appears, therefore, necessary to define the term "time of setting of a gel" before applying any method for measuring the same. It is now fairly well established that the process of gelation includes (i) the formation of the colloidal solution of the gelling substance, (ii) its coagulation, hydration and agglomeration, and (iii) the formation of the specific structures; other structural changes which eventually take place such as synersis, etc., can be neglected. A gel should, therefore, be considered as set only when all the three processes mentioned above are complete and not when the gelling substance has gone through a certain part of the increased hydration and the increased viscosity of the second process. In such a case a method such as the optical method which takes into account all the changes which the gel-forming mixture undergoes during gelation, should give a reliable value of the time of setting of the gel. The application of such a method will, of course, be limited to those gel-forming mixtures which are clear before gelation starts and continuously change in transparency till all the

changes involved in the setting of a gel are complete.

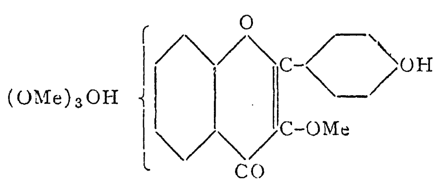
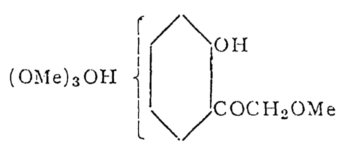
The Constitution of Calycopterin.

THE anthelminthic constituent, *calycopterin*, of the leaves of *Calycopteris floribunda*, Lamk., has been shown[1] to be a dihydroxy-tetramethoxyflavone and to be identical with the yellow colouring matter isolated by Karrer[2] as a bye-product in the preparation of digitoxin from the leaves of a Spanish *Digitalis.*[3] On fusion with alkali calycopterin gave *p*-hydroxybenzoic acid and the stability of an alkaline solution of the substance to oxidation by atmospheric oxygen pointed to a methoxyl in the 3-position. Calycopterin was represented as (I); with the limited amount of material available the identification of the water-soluble phenol obtained in the course of the degradation with alkali was not practicable; isolation of the phenol in quantity and the orientation of the two hydroxyls and three methoxyls would in any case be extremely difficult in the case of a pentahydroxybenzene derivative. Repeating the alkaline hydrolysis we have now prepared the ketone (II), the colour reactions of which, however, failed to give a definite indication of the position of the hydroxyl in the fused benzene ring of the flavone.

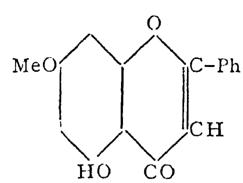
In a recent communication[4] to the *Journal of the Chemical Society* we have reported the demethylation of 5-methoxyflavones to 5-hydroxyflavones by means of aluminium chloride; under prescribed conditions the methoxyl in the 5-position is preferentially attacked and the method may be utilised for the synthesis of partially-methylated polyhydroxyflavones such as tectochrysin (III) and genkwanin (IV). The synthesis of the latter on these lines has just been completed and will be reported elsewhere; the oxidation of the chalkone (V) with selenium dioxide[5] gave the flavone (VI), which was successively debenzylated and demethylated to genkwanin (IV). In the course of this work it was apparent that the action of aluminium chloride on a methoxyflavone might be fruitful as a diagnostic test for the presence of a methoxyl in the 5-position; its application to the specific instance of calycopterin has revealed the position of the



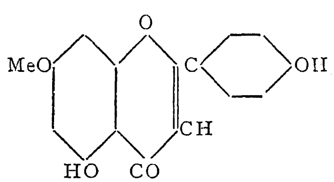
(I)



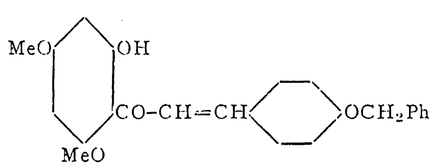
(II)



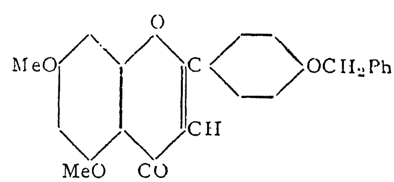
(III)



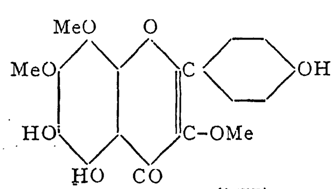
(IV)



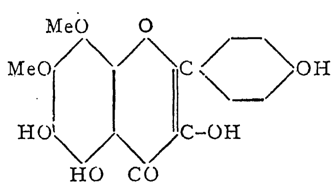
(V)



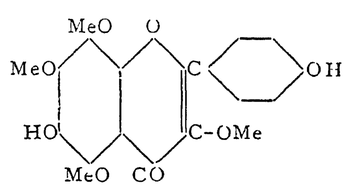
(VI)



(VII)



(VIII)



(IX)

hydroxyl in the fused benzene ring. The treatment of calycopterin with aluminium chloride has resulted in a new flavone, which exhibits the usual properties of a catechol derivative, *e.g.*, the characteristic red-brown colouration with ammonium molybdate and acetic acid,[6] and must therefore be 5 : 6 : 4′-trihydroxy-3 : 7 : 8-trimethoxyflavone (VII) or 3 : 5 : 6 : 4′-tetrahydroxy-7 : 8-dimethoxyflavone (VIII); the second alternative needs to be considered since we have noticed that a 3-methoxyl is also susceptible to demethylation by aluminium chloride. The second hydroxyl in calycopterin being in the 6-position, calycopterin may now be formulated as 6 : 4′-dihydroxy-3 : 5 : 7 : 8-tetramethoxyflavone (IX).

Condensation of ω-Bromoacetophenone with 1-*o*- Aminophenyl-3-Phenylthiocarbamide.

THE condensation of ω-bromoacetophenone with 1-*o*-aminophenyl-3-phenylthiocarbamide yielded a compound (m.p. 230° decomp.; empirical formula $C_{15}H_{13}ON_2SBr$) to which a heptathiodiazine structure was assigned by me.[1] Pathak[2] has obtained, by carrying out the same condensation, a compound (m.p. 223° decomp.) possessing the same empirical formula and finds that it is the hydrobromide of a weak heterocyclic base. These two compounds have been regarded by him as identical.

That the compound (m.p. 230° decomp.) isolated by me is not the hydrobromide of a heterocyclic base but possesses the heptathiodiazine structure is definitely proved by the fact that it is, as already mentioned in my original paper, acidic in nature being soluble in cold dilute alkali and precipitated by acids. This property, *viz.*, that the compound is unaffected by sodium bicarbonate solution and is precipitated *unchanged* by acid from its solution in alkali, has been again established and dispels any idea of the compound being a hydrobromide. The compound melts with decomposition to form a dark brown viscous liquid which emits smell of ω-bromoacetophenone.

In view of the properties of my compound as mentioned in my original paper, it is really surprising how Pathak could regard the two compounds as identical, and his conclusion seems not to be well founded. From Pathak's observations, it seems very probable that his compound is entirely different from mine and slight difference in experimental conditions employed by him may account for the formation of a different compound.

My compound (m.p. 230° decomp.) can be prepared as follows: An intimate mixture of the reactants (equimolecular proportions) is mixed, at ordinary temperature, with glacial acetic acid and shaken, when a clear solution is obtained accompanied by rise in temperature. In about an hour a solid is precipitated which after precipitation from an alkaline solution by acid is crystallised twice from glacial acetic acid in colourless needles.

Pathak's further observation by way of comparing the chemical characteristics of both the compounds seems to be desirable.

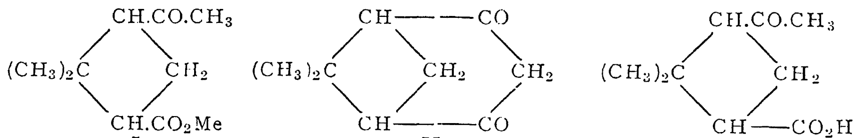
Synthesis of "Ketonopinone" (4 : 6-Diketonopinane).

THE synthesis of pinononic acid (III) and its methyl ester (I) starting from *cis*norpinic anhydride has been reported by us.[1] The conversion of (I) into ketonopinone (II) has now been effected by means of sodium in toluene or sodium methoxide in alcohol solution. Ketonopinone (II), m.p. 104°, purified through its copper derivative (sint 238°) gives a violet coloration with $FeCl_3$, dissolves in sodium bicarbonate, decolourises alkaline permanganate and absorbs bromine in chloroform solution. The constitution was confirmed by hydrolysing it with baryta to pinononic acid (III). Reduction of this diketone to nopinone and nopinane is in progress.



I II III

It can now be observed that this constitutes a *total* synthesis of a bicyclic compound in the pinane group; Ruzicka's synthesis of pinocamphone, α- and δ-pinenes[2] involved the use of pinonic acid yet unsynthesised. Work on the synthesis of pinonic acid starting from norpinic acid is in progress.

Full details will shortly be published elsewhere.

A Manometric Device for Gas Analysis.

FOR the quantitative measurement of the respiratory gaseous exchange in plants Haldane's gas-analysis apparatus is generally used. The apparatus is undoubtedly highly accurate but requires considerable skill before it can be used with discrimination. The construction of the apparatus is complex and an accidental breakage in the glass parts is not easily repaired. In the course of some physiological investigations connected with the Fruit-Preserving and Fruit-Canning industries where a high degree of accuracy is by no means essential, the need was felt for simple and effective means of gas analysis. With this object in view a simple apparatus for gas analysis was constructed in this laboratory and has been in use for some time with satisfactory results. Over the existing forms of the gas-analysis apparatus, it possesses the following advantages: (1) Sampling the gaseous mixture is exceedingly easy. (2) The use of phosphorus[1] as an absorbent for oxygen instead of potassium pyrogallate obviates the necessity of keeping the gaseous sample in a state of continuous agitation which is often very tiring.

The principle of the apparatus (Fig. 1) consists, in brief, in measuring the pressures exercised by the various constituents of a gaseous mixture. As the partial pressure of a component is proportional to its concentration in the gaseous sample and the sum of the various partial pressures is equal to the total pressure exerted by the gas sample, the percentage content of the component, say x, is easily computed :—

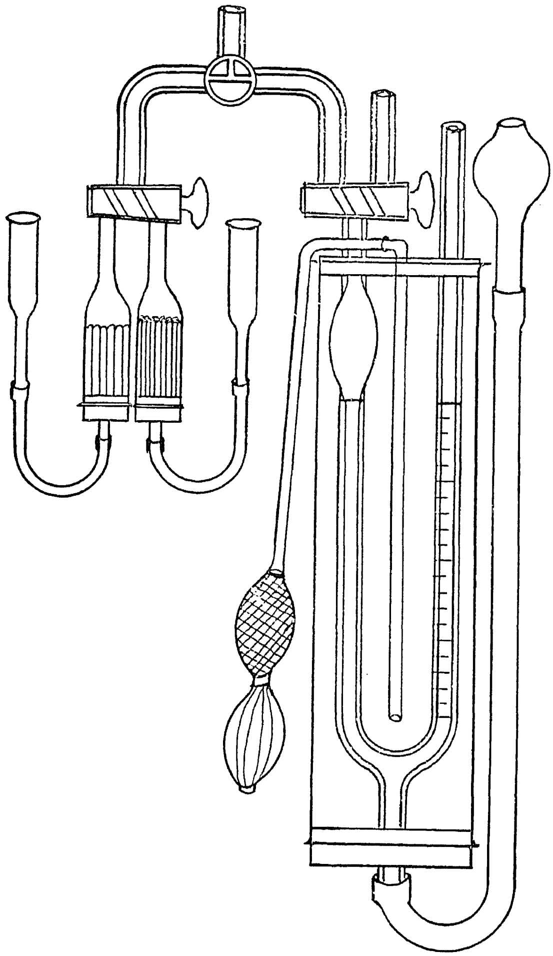

Fig. 1.
A manometric device for gas analysis.

$$x = \frac{h \times 100}{H_0}$$

where h=the partial pressure of the component under consideration, and H_0 = atmospheric pressure in mm. Hg.

A detailed description of the apparatus will appear elsewhere.

Uric Acid Crystals in the Blood Plasma of a Fowl suffering from Pyo-nephrosis consequent on Vitamin A Deficiency.

AN investigation is being undertaken on the growth of embryonic tissues in vitro on plasma taken from vitamin A deficient fowls and rats. In the course of the investigation blood was taken from a fowl which had been fed for 12 weeks on the following diet :—

Milled Rice	..	65 parts.
Ground Whole Rice	..	15 ,,
Casein	..	12 ,,
NaCl	..	1 ,,
$CaCO_3$	..	1 ,,
$Ca_2H_2(PO_4)_2$	..	1 ,,
Dried Yeast	..	5 ,,

Under light ether anæsthesia blood was drawn from the carotid artery. Directly after centrifuging the plasma appeared quite clear. In spite, however, of the fact that the blood was drawn through an ice-cold paraffined canula into a paraffined centrifuge tube and kept in ice packing until centrifuging, clotting occurred within a few minutes of centrifuging. The plasma of a normal fowl, collected and treated in this manner, can be kept in cold storage for months without clotting. In the present instance it was observed that the serum exudating from the clot was turbid and under the microscope it was found to contain a mass of needle-shaped crystals (see accompanying microphotograph, magnification × 103). A post-mortem examination of the fowl revealed that the kidneys were completely disorganised, being practically "bags of pus". The comb showed dryness and keratinisation, and, in places, ulceration. The liver was found to be devoid of vitamin A by the arsenic trichloride test.

Microphotograph of crystals. × 103.

The condition of the kidneys suggested that crystals in the blood might be uric acid. Under the microscope it was observed that they dissolved completely in dilute potassium hydroxide, but were insoluble in dilute acetic acid and in distilled water. A quantitative estimate of uric acid content was made by Benedict's method. For purposes of comparison, similar tests were carried out on the plasma of 2 fowls, with apparently normal kidneys, fed respectively on the mixed stock diet and on a "control" diet similar to the one described above except that it contained 3 per cent. of cod liver oil. Results were as follows :—

		Uric acid in plasma (mgrms. per 100 c.c.)
Fowl on stock diet	..	12·50
,, "control" diet	..	8·34
,, vit. A deficient diet		375·00

There seems no doubt that the crystals were uric acid. A uric acid plasma content about 30 times greater than values obtained from two fowls with normal kidneys, seemed sufficiently interesting to report. The presence of excessive uric acid in the blood was not, of course, directly due to vitamin A deficiency, but was caused by a pyo-nephrosis consequent on vitamin A deficiency. It need hardly be said that the plasma from the deficient bird, choked with uric acid crystals, could not be used for tissue-culture experiments.

Thanks are due to Dr. W. R. Aykroyd, Director of the Laboratories, for permission to publish this letter.

Fusarium Wilt in Sann Hemp.

IN his recent work[1] Mitra brought forth evidence that under the conditions at Pusa wilts in *Crotalaria juncea* and in *Cajanus indicus* are caused by similar physiologic strains of *Fusarium vasinfectum*. Although the isolates from these two hosts were able to cross inoculate each other, they always failed to infect cotton and *vice versa*.

In their study of the Fusarium wilt in sann hemp, the results of which will be published separately, the present writers had obtained evidence that *Fusariun vasinfectum* was a highly specialised species and in no case did the form on sann hemp pass to pigeon pea, and *vice versa*. These results were contrary to those reported by Mitra, and it was therefore decided to test the correctness of Mitra's conclusions by a series of well-designed experiments. Cultures of *Fusarium vasinfectum* from sann hemp and pigeon pea grown in Pusa and in its neighbourhood were secured through the kindness of Dr. Mitra, and were compared with similar cultures obtained locally. The seeds of a wilt-resistant type, T. 80, and of a susceptible type, T. 5, of pigeon pea were also secured from Pusa.

Cross inoculation experiments were made in soil temperature tanks of Wisconsin type at 28° C., the optimum temperature for the development of wilt. In all cases seeds of sann hemp and pigeon pea were surface-disinfected before sowing in pots. In these experiments cultures of *Fusarium vasinfectum* from sann hemp did not infect pigeon pea and *vice versa*, although control plants in all cases gave a high percentage of deaths.

These results will be reported in detail separately.

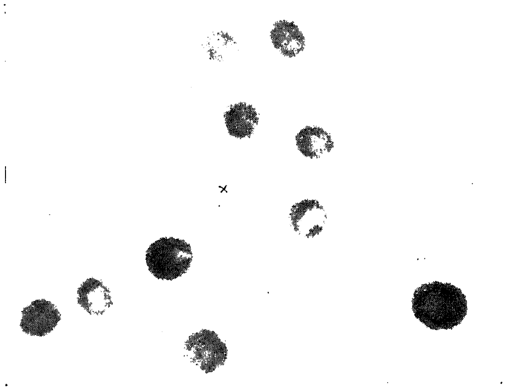
Dummy Pollen.

IN the course of the examination of innumerable pollen grains in many varieties of *Sorghum* since 1931, a peculiar kind of pollen was met with. An examination of pollen grains under the microscope shows constantly a few grains devoid of solid contents (see Figure). In size they are comparatively small (31 μ to 34 μ). Due to the pressure of the sap inside, they are not shrivelled but retain normal shape. They do not germinate and usually plasmolyse in the culture medium. Pollen studies have not, so far as we are aware, recorded non-germinating pollen of this peculiar type. Similar pollen has been met with in the allied wild grasses, *Andropogon annulatus* and *Andropogon pertusus*, L. In the eight different varieties of *Sorghum* examined, the incidence of this pollen ranged from 2·3 to 13·5 per cent. In the day flowering *S. margaritiferum* it was only 0·4 per cent. The higher types of cultivated *Sorghum* had a lower percentage of this Dummy Pollen. Dummy Pollen is slightly less in the anthers at the base of the earhead.

In the other millets this pollen is met with in *Pennisetum typhoides*, Stapf and Hubbard (also a millet of African origin), which like



× Dummy pollen in *Sorghum*. × 150.

Sorghum has both hermaphrodite and antheriferous flowers. Instances have been met with in both *Sorghum* and *Pennisetum* in which a non-dehiscence of anthers proved to be due to an extreme paucity of this Dummy Pollen, it being under one per cent. in the non-dehisced ones, and over seven per cent. in the dehisced ones. This points to the probable rôle of this Dummy Pollen as a specialisation ensuring dehiscence in these predominantly night-flowering millets. An experience has been met with in which this poverty of Dummy Pollen and the attendant non-dehiscence of anthers proved a simple recessive to the presence of the normal proportion of such pollen and the consequent dehiscence of anthers. A fuller account of this experience is being published elsewhere shortly.

Forked Awns and Leaf-Blades in Sorghum.

AMONG cereals, maize and sorghum have big leaf-blades. These blades have an entire margin and a single central, well-marked midrib running their entire length. This midrib occasionally forks into two

Fig. 1.

(G. N. Rangaswami Ayyangar and P. Subramanyam, 1930).[1] A second aberration in the leaf-blade of sorghum has been met with in some selections. This occurred in three single plant selections from a variety from Bihar (India) and in five single plant selections taken from Kafir imported from America. The aberration is a disturbance in the entirety of the margins of the leaf. In the two halves of the blade there appear deep marginal indentations giving the leaf a tri-dentate appearance (Fig. 1).

Forking occurs usually in the apical third of the leaf, sometimes in the middle third and rarely in the basal third. It forks usually in one leaf of the adult plant and rarely in two leaves. In one instance three leaves in a plant manifested this forking. The forking may show in any leaf of the plant from the flag downwards. It tended to show a little more frequently in the eighth or ninth leaf from the top. Leaves of side-shoots may also fork. In the population examined, 5–13 per cent. of the plants in Kafirs and 26, 30 and 32 per cent. in the three Bihar families manifested forked leaves.

Of the eight families, the five Kafirs were awnless. The three Bihar pure lines were awned. An examination of the awns showed that in every ear-head some of the awns forked in degrees. Ten ear-heads were examined in detail and each ear-head had an average of 1350 awns. Of these an average of 8 proved to be forked awns (Fig. 2). The forking varied from a slight

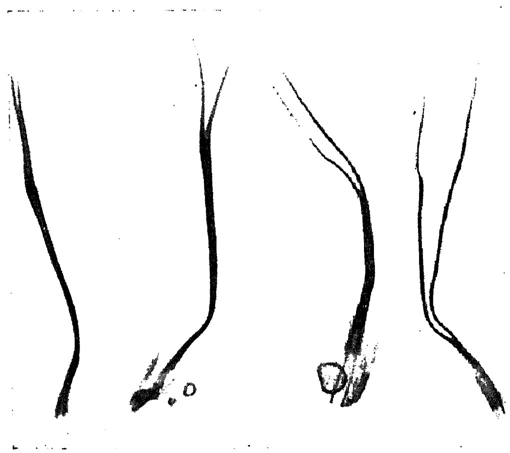

Fig. 2.

bifurcation at the extreme tip of the subule to an extension of the forking to the whole of the subule. In some cases the forking extended to the base of the column. Narrow as the awn is, the forking did not halve the thinness, but each awn of the fork retained the usual narrow width, so much so that in the unforked portions they were noticeably wide.

As in the case of midrib forking, the manifestation of this forking of the leaf-blade need not appear in every plant, nor in every leaf. If it does not manifest in the adult stage, evidences of its presence are betrayed by the leaves of the seedlings. In one pure line six selections that showed forked leaves in the adult plants and three that did not show forked leaves, were selected and germinated. Instead of the usual 95 per cent. of normal germination, all these gave only 75 per cent. In every one of the selections about 8 per cent. of the seedlings showed forking in one or other of the first four seedling leaves. Since all of them gave some plants with forked leaves, this character must have been nascent in the 3 adults that did not show it. In the seedlings the forking, when it showed, was most frequent in the first leaf and next in the second leaf. The peculiarity of the forking in the first two leaves that lacked a well-defined midrib was, that the forking split the blade into two. When this forking was intense it easily invaded the leaf-sheath past the nebulous ligular zone. In 20 instances splitting of the coleoptile was noted. None of these 20 seedlings survived.

This concurrent manifestation of a very rare, probably atavistic, abnormality in two such homologous organs as the leaf-blade and the awn is interesting.

Fate of the Embryonic Membranes in Insects.

THE formation of two embryonic membranes, the amnion and the serosa, is characteristic of insects, although in exceptional cases one or both of these membranes may be absent. Regarding their fate, four main types have been so far recognised, *viz.*, involution through the formation of a dorsal amnio-serosal sac ; involution of the amnion with the retention of the serosa ; involution of the serosa with the retention of the amnion; and finally, retention of both the amnion and serosa (*vide* Imms).[1] In all these cases, except the last one, the membranes degenerate some time before hatching. The dorsal organ may be formed from the amnion or the serosa or both.

In the Tettigonids *Xiphidium* and *Orchelimum* (Wheeler)[2] and in the Mantid *Paratenodera sinensis* (Hagen)[3] a third embryonic membrane, the indusium, occurs besides the amnion and the serosa. In the Tettigonids a single dorsal organ is formed from the indusium, while the other two membranes are dissolved into the yolk. In *Paratenodera*, on the other hand, *two* dorsal organs are formed, one from the serosa and the other from the indusium, while the amnion degenerates ; this formation of two dorsal organs is unique among insects.

In some of the parasitic Hymenoptera, a single, peculiar membrane, the throphamnion, is formed. It is not comparable with the other embryonic membranes and appears to be a structure *sui generis*, being formed, in some cases, from the polar bodies (Silvestri).[4] In most cases it degenerates, but in some the cells dissociate from one another, round themselves and increase in size and live for a long time in the body fluid of the host where they serve as food for the parasitic larva. A similar fate occurs in regard to the serosa of several parasitic Hymenoptera and evidence thereto has been marshalled recently by Jackson.[5,6]

It will be seen from the above summary that no case has so far been reported in which a portion of the serosa completely degenerates whereas the other portion persists until hatching. During my investigations on the embryology of the European Migratory Locust, *Locusta migratoria* L., I have discovered such a condition. During blastokinesis or turning round of the embryo, the amnion and the serosa rupture. The whole of the former forms a provisional dorsal closure of the embryo and then quickly degenerates. The serosa, on the other hand, is divided into two portions. By far the largest portion of it goes to form the dorsal organ, while a very small, saucer-like area (Fig. 1, *Q*) remains at the posterior or micropylar pole of the egg and persists until hatching. This area may be called the *posterior serosal patch* and has so far not been described in any other insect. Further, it is interesting to note that this posterior serosal patch does not remain unchanged, but undergoes definite changes of organisation. At first the cells of this area are irregularly arranged. After about two days (at 33° C.) of its separation from the main serosal mass, it shows (Fig. 2) a bi-layered arrangement of its cells, with a rather indistinct space (Fig. 2, *O*.) in between,

This arrangement persists until hatching when the posterior serosal patch is cast off with the egg-shell.

Finally, I should not fail to point out that the occurrence of this phenomenon, *viz.*, the

persistence of the posterior serosal patch until hatching and the degeneration of the rest of the serosa long before hatching, provides us in the locust a very suitable material for the investigation of an interesting and important problem of Entwicklungsmechanik. Is the degeneration of the anterior portion of the serosa induced by its association with the yolk at the cephalic end of the embryo? Two methods of attack are possible for the solution of this question. The small posterior serosal patch could be transplanted near the cephalic end of the embryo in the neighbourhood of the dorsal organ, and observations made as to whether it degenerates there or persists as in its original place. I have performed several such experiments without success. The difficulty lies in the fact that the locust egg invariably dies a few hours after it is experimented upon. In view of this difficulty for the solution of which I, at present, cannot see any way, the second method of attack, which I have not so far tried, appears to be much more hopeful. It would be interesting to know whether these two portions of the serosa which behave so differently in the living egg would do the same in *in vitro* cultures. Artificial culturing of insect tissues is extremely difficult because it is by no means easy to obtain sufficient quantities of a suitable culture medium. For this purpose I would refer to the papers of Goldschmidt[7] and Frew[8]. Once a suitable culture medium is obtained, I have no doubt that the serosa would provide an exceptionally good material for *in vitro* cultures.

The Respiratory Mechanism of the Frog.

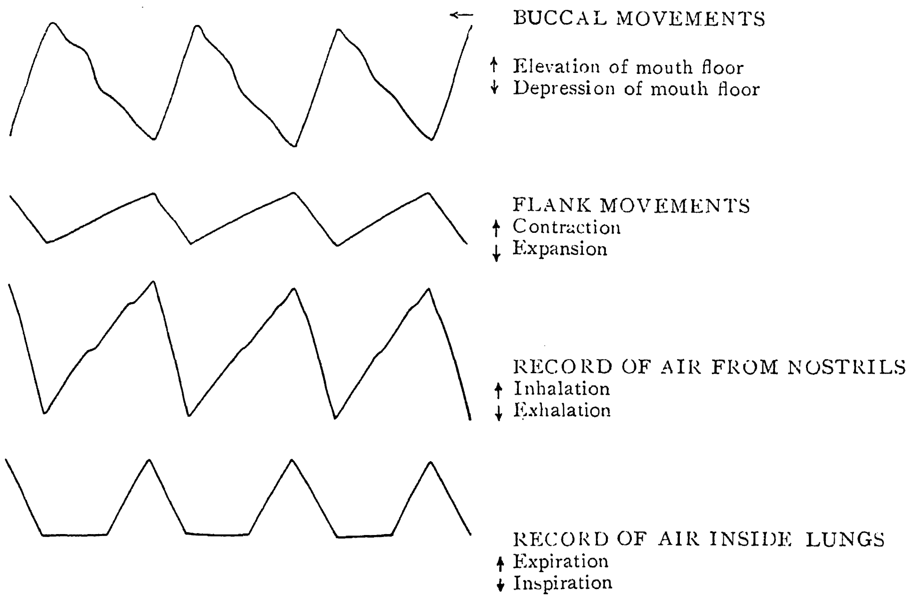
EXCEPT Wedenski and Willem (1918), all others, Gaupp (1900), Baglioni (1901), Bruner (1914), Goppert (1903) and Heinemann (1884), appear to have made no experimental observation; and of the former two, Willem alone has used the graphical method. According to Gaupp, the two processes—expiration and inspiration of air into the lungs—are preceded by a third process—aspiration of air into the mouth. This account does not explain the exit of air

from the mouth. Others, principally Willem, therefore describe two phases (buccal ventilation and pulmonary ventilation) taking place alternately. Almost all accounts state or imply that the lungs and the mouth are ventilated one after the other. Experiments show that they are ventilated simultaneously and that the breathing mechanism is much simpler than has been described hitherto.

The movements of the flanks were recorded on smoked paper and it was found (*a*) that they were uninterrupted, continuous and regular; (*b*) that they are of uniform magnitude. The buccal movements when similarly recorded on smoked paper showed that they were also continuous and uniform. A simultaneous record of both the buccal floor and the flanks showed that when the mouth-floor is raised, the flanks distend and when the flanks contract the mouth-floor is lowered. It is inferred from this that when the buccal floor is elevated, the mouth cavity is reduced and the air is pumped into the lungs and that when the body wall contracts, the air is pressed out of the lungs into the mouth.

The opening and closing of both the nostrils as well as the glottis was observed by graphical records of the air currents. The air going in and out of the nares was led into a tambour by a mask applied to the snout and was recorded—the graph showed uninterrupted inhalations and exhalations. By taking this record of air along with the movements of the buccal floor, it was found that when the mouth floor was raised, the air was exhaled and was inhaled when the mouth floor was lowered. The hyoid apparatus and associated muscles are capable of raising the buccal floor.[1] The air currents were also recorded with the movements of the flanks and the graphs showed that when the air goes out of the nostrils (exhalation), the flanks dilate (inspiration) and when the flanks collapse (expiration), the air enters the nostrils (inhalation). The closing and opening of the glottis was observed by anæsthetising a frog and introducing a slender tube into each lung and leading the air in the lungs into a tambour and thus recording the entrance and exit of air from the lungs. This graph also showed regular and uniform expirations and inspirations.

Scheme of records to illustrate the synchronism of various movements concerned in the respiration of frog.



Putting together the tracings of the buccal movements, flank movements, air currents from nostrils and from lungs the interpretation of the respiratory mechanism would be as follows: When the buccal floor is lowered, outside air is inhaled through the nostrils into the mouth cavity while the air inside the lungs is sucked (and also squeezed by the body wall) through the glottis into the buccal cavity. Thus the fresh and the impure air mix in the mouth chamber. When the buccal floor is elevated, this mixed air rushes out of the nostrils as

well as into the lungs. The graphs of the air currents make it clear that neither the nares nor the glottis are completely closed for any long interval. They constrict in such a way that the buccal floor oscillations increase or decrease the pressure in the mouth chamber.

The rôle played by the body wall and the elasticity of the lungs in this mechanism can be demonstrated by preventing the mouth of a frog from closing and thus throwing the buccal floor out of action. Graphical records of the flanks show a series of expirations followed by no inspiration—until the expirations become extremely feeble. Thereafter each weak expiration is followed by a feeble passive inspiration and the frog continues to breathe in this way. This co-operation of the buccal floor and the body wall serves to lead up to the reptiles the more primitive members of which employ the buccal floor as well as the ribs to ventilate the lungs.[2]

The Sub-central Foramina of the Squamata.

SINCE writing a note[1] on the presence of paired apertures on the ventral aspect of the vertebral centra in the common house-gecko, *Hemidactylus flaviviridis* Rüppel, I have been on the look-out for previous references to them in zoological literature. A consultation of such standard text-books of zoology as Sedgwick[2], Wiedersheim and Parker[3], Hertwig and Kingsley[4], Kingsley[5], Reynolds[6], Parker and Haswell[7], Hyman[8], Goodrich[9] and de Beer[10], shows that these apertures have somehow escaped the general observation of many eminent zoologists. As pointed out by Ramanujam and Ramaswami[11], however, Owen[12] recorded them for the Ophidia long before Mookerjee and Das[13]. More recently, Camp[14] has studied and sketched the vertebræ of 22 species of lizards for this feature. He says:

"The size of the intervertebral canals, large in the Geckonidæ and Xantusiidæ, undergoes reduction in the more advanced groups. The paired sub-central foramina, present in geckos, pygopodids and amphisbænians.... appears less frequently among the Scincomorpha and are absent in the higher anguimorphs and in the chamæleons."[15]

This statement seems to imply that the presence and size of these apertures is a primitive feature in lizards, and that it, therefore, adds to the "Paleotelic Weight"[16] of the animals in which it is found. If this notion is right, it is a significant fact that these apertures in *Hemidactylus* are larger in size relatively to the size of the whole centrum than in the vertebræ of the four species of Geckonidæ, figured by Camp, *viz.*, in *Thecadactylus rapicauda*, *Tarentola cubana*, *Sphærodactylus macrolepis* and *Coleonyx variegatus*.

Goodrich[17], although he makes no mention of the presence of sub-central foramina in this work, gives an instructive diagram about the "relations of *sclerotomes* and development of *vertebral column* in *Amniota*", which seems to suggest that these apertures are really intersegmental in position and represent the sclerotomic segmentation of the earlier stages in the case of the adult. The position of the intersegmental artery in his diagram (Fig. 1) coincides very well with the

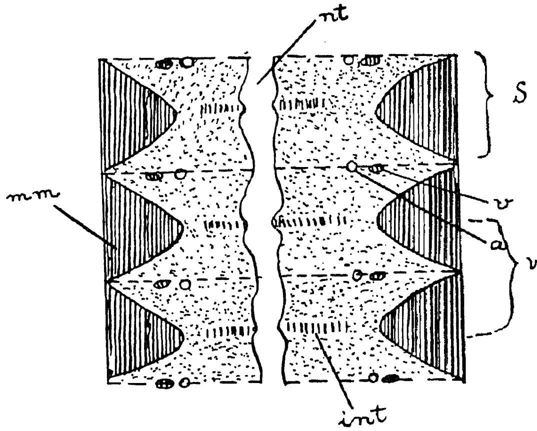

Fig. 1.

Diagram illustrating relations of *sclerotomes* and development of *vertebral column* in *Amniota* (simplified from Goodrich).

a, intersegmental artery; *int*, intervertebral ligament; *mm*, myomere; *nt*, notochord; *S*, region between two transverse broken lines occupied by one body segment; *v*, intersegmental vein; *vs*, region occupied by one vertebral segment composed of a half-sclerotome from each of two consecutive segments.

position of the sub-central foramina in *Hemidactylus* (Fig. 2) and other Squamata. Thus these apertures are probably reminiscent of a former condition and may be regarded as primitive features.

Granting the intersegmental position and the primitive nature of these foramina, it

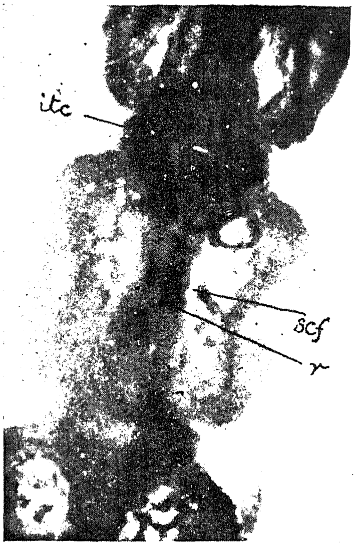

Fig. 2.

Photomicrograph of the ventral aspect of the centra in *Hemidactylus flaviviridis*.

itc, intercentrum ; *r*, median ridge ; *scf*, sub-central foramen.

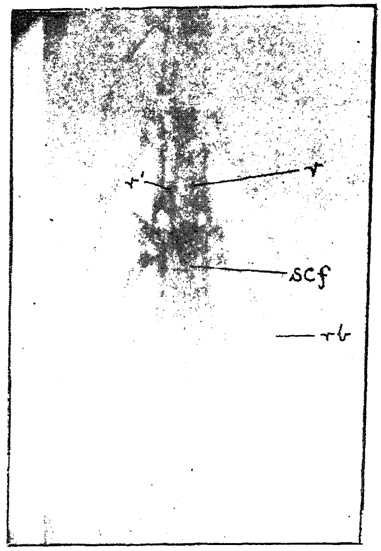

Fig. 3.

Photomicrograph of the Vertebral Column of *Typhlops braminus* from ventral aspect.

r, r', ridges ; *rb*, rib ; *scf*, sub-central foramen.

would be interesting to find out whether any types of the Amphibia, extinct or living, show these apertures at any stage of their development. An examination of the vertebræ of the extinct genus *Arœoscelis* Williston, which is said to represent the ancient stem from which the Lacertilia arose,[18] might be worth while in this connection, as also a fresh scrutiny of the vertebræ of *Sphenodon*. In the latter case, I might mention that Günther[19] and others do not make any mention of these apertures. I hope that those zoologists who have access to this type of materials will throw some light on this question.

In the present stage of our knowledge, it is impossible to be certain whether the *single* sub-central foramen of *Typhlops*[20] is actually homologous to the *paired* apertures found in lizards and in some snakes. I am, however, inclined to believe that it is not. Recently, I prepared two alizarin-stained skeletons of this snake to confirm Mookerjee and Das's findings, and my attention was especially attracted by two differences in this connection. In the first place, the apertures in *Typhlops* (Fig. 3) are placed far more anteriorly than those in *Hemidactylus*, being just a little behind the anterior ends of the centra. Secondly, two slight ridges in the case of *Typhlops* start at the posterior end of the ventral aspect of each centrum and converge towards each other as they run forwards, the single sub-central aperture being situated where they should meet together. In *Hemidactylus*, on the contrary, there is a prominent single median ridge, situated longitudinally on the ventral aspect of each centrum, and the apertures in question lie one on each side of it.

An examination of the vertebræ of two other families of Snakes—*Boidæ* (*Eryx jaculus* Linné, *Python molurus* Linné) and *Colubridæ* (*Ptyas mucosus* Linne', *Naia tripudians* Merr.)—shows the presence of *paired* (not single) sub-central foramina, and thus the case of *Typhlops*, as far as has been investigated up to the present, is a solitary one amongst the Ophidia. However the sketch of the ventral aspect of a vertebra of the extinct snake *Palæophis typhæus* Owen, as given by Lydekker,[21] raises the suspicion that this snake had not two sub-central apertures like the *Boidæ* and the *Colubridæ*, but a single aperture which was situated nearer the posterior than the anterior end of the centrum. This feature, if confirmed in actual specimens of the vertebræ, might prove important insomuch as it would make *Palæophis* appear to be related to the *Typhlopidæ* rather than to the *Pythoninæ*, with which latter it is believed to have affinities.

Some time back, I requested Mr. E. R. Gee, Director, Geological Survey of India, to

scrutinise the vertebræ of *Palæophis* for this feature, but unfortunately the palæontological collection in his charge does not include any vertebræ of extinct species of Snakes and Lizards. I hope, however, that some one else who has access to such material, might examine them. I am grateful to Mr. Gee for kindly examining the fossil vertebræ of several *extant* species of Snakes for me and for reporting the presence of paired appertures on the ventral aspects of their centra. "The apertures," he says, "are in the form of narrow slits."

A Contribution to the Stratigraphy of Bagh Beds.

BAGH BEDS representing the marine facies of the Cretaceous of the Narbada valley, occur in several detached areas on the northern side of the Narbada from Barwai on the Khandwa-Indore railway line on the east to Wadhwan in Kathiawar on the west. The earliest references to the fossiliferous limestones of these formations are by Dangerfield in 1818, and by Colonel Keatinge in 1856[1] but the geology of the areas was first worked out by W. T. Blanford[2] and later studied in detail by P. N. Bose.[3] These beds occur as inliers in the Deccan Traps, the principal exposures being those near Chirakhan, Bagh and Kawanth. According to Blanford and Bose the stratigraphical sequence obtaining in these areas is as follows :—

		Position of the new beds
Deccan Trap.		Fossil Wood and Breccia Zone
Bagh Beds	(Upper) Coralline Limestone	
	Deola-Chirakhan Marl	
		Lower Coralline Limestone
	Nodular Limestone	
	Nimar Sandstone	
Gneisses ; Gondwanas, etc.		

During a short visit to these formations in the Chirakhan area, a few months back, the authors have traced a new bed in the above sequence in this region : A bed of bryozoan limestone, 3–5 ft. thick, occurring between Nodular Limestone and Deola-Chirakhan Marl and provisionally named here as Lower Coralline Limestone.

This horizon has been traced round Badiya, Chirakhan, Sitapur, Audiyapur and Deola, the best development, however, occurring on hillocks near Deola and Sitapur. It is separated from the (Upper) Coralline Limestone by the bed of soft Deola Marl which on differential denudation has left the Coralline Limestone bands, both at the top and at the base, as projecting rock masses. In certain places, the Lower Coralline Limestone band is very thin and inconspicuous and as such escapes notice. It is a hard granular rock, brownish yellow in colour and is full of bryozoa. The fossils provisionally identified from this horizon include *Eschara*, *Ceriopora*, *Thamnastræa*, *Hemiaster*, small

rhynchonellids, *Placenticeras*, *Inoceramus*, *Cardium*, *Venus*, etc.

The Upper Coralline Limestone of the Chirakhan-Deola area resembles the Lower Coralline band to a great extent in lithology and in external appearance, and but for the intervening band of Marl, cannot be easily distinguished. In certain western exposures of the Bagh Beds, Coralline Limestones are reported to be capping Nodular Limestone with the supposed intervening Marl missing, its absence being attributed to its soft nature and its consequent denudation. In the light of the present discovery it appears very probable that the Coralline Limestones of the western exposures are in their normal position and correspond to the Lower Coralline Limestone horizon of the Chirakhan area and not to the (Upper) Coralline Limestone as suggested by the previous authors.

The discovery of a lower horizon of Coralline Limestone therefore necessitates the amendment of the stratigraphical sequence of the Bagh Beds as shown in the above Table.

On a Fossil Wood and Breccia Zone in the Deccan Trap in Deola-Chirakhan Area, Central India.

DURING a recent visit to the Chirakhan area, we have noticed more or less continuous zone of fossil wood and breccia at the contact of Traps and the Bagh Beds. It is a very definite horizon being met with in almost all the localities wherever the Bagh Beds are overlain by the Traps. It has a sharp junction with the underlying coralline limestones but has no such demarkation on its upper limit where it merges into the normal traps.

In most places this zone is characterised by the exclusive abundance of fossil wood strewn over the surface, in a loose condition, under a thin covering of trappean soil. Fossil wood specimens, which to all appearances are dicotyledonous in nature, range in size from small fragments to huge tree trunks about 4 ft. in diameter and more than 40 ft. in length. The wood has been completely jasperised and is left with practically no trace of internal structure; the gross surface features and sometimes the rings of growth are very clearly seen.

In certain localities as near Badiya, Phutabaodi and Chirakhan, in addition to fossil wood, we also observe in the same zone an extensive occurrence of breccia in the form of a scattered band irregularly spread over the surface. Anything approaching a regular band occurs only at Badiya. The rock is a hard indurated type of breccia composed of variously sized angular or sub-angular fragments of limestones, sandstones, jasper and pieces of fossil wood, all heterogeneously cemented in a calcareous and ashy material. The fragments vary in size from tiny grains to blocks more than a foot in diameter. This unassorted and fragmental nature of the material may be due to absence of any sorting action of water or may indicate formation of the rock *in situ*. The presence of the ash in the matrix demonstrates its close association with the volcanic activity as also does the presence of jasper which is usually found in steam cavities in lavas.[1] The complete loss of internal structure in the fossil wood may be due to the heat of contact with the lava or due to rapid replacement of wood tissues by heated solutions. These considerations together with the strictly sub-trappean position of the band in the field strongly suggest that the formation of the breccia and the fossilisation of the wood are very intimately connected with the activity of the lava flows. It is not thus unlikely that the forest growth together with the rock debris was overwhelmed by volcanic ash and was subsequently buried under a lava flow, the heated fluids bringing about the cementation of the debris into a hard breccia and also the fossilisation of the plant remains with almost complete obliteration of the structure, the cold surface waters having little part in the formation of either. The fossil wood and breccia thus characterise the lowest flows of the Deccan Trap in this region.

The Age of the Inter-Trappean Beds near Rajahmundry.

IN the course of a recent examination of the several inter-trappean exposures near Kateru, Pungadi and Dudukur, we have made two important observations which throw some light on the age of the Deccan traps—a subject on which there has recently been some comment by Dr. Sahni[1] and Dr. Fox.[2]

Thin sections of the limestones forming the lowest beds of the Deccan inter-trappean series near Pungadi and Dudukur have revealed, among other fossils, remains of algæ belonging to the family Dasycladaceæ. Some of these slides were sent to Dr. Julius Pia (of the Natural History Museum, Vienna) for identification, and he has recognised *Acicularia* as the most common of these algæ. It is well known that, though members of the family Dasycladaceæ were fairly common throughout the Mesozoic, *Acicularia* is essentially a Tertiary form. This find of a Tertiary fossil alga from these beds is of great significance, especially in view of Dr. Sahni's discovery of fossil plants of Tertiary affinities among the fresh water inter-trappeans of Nagpur-Chhindwara region.

Among the inter-trappean beds near Kateru, we have noticed the occurrence of numerous Charophytic remains in an excellent state of preservation. Among these the following species of *Chara* have been tentatively identified: *C. Wrightii*, *C. helicteres*, *C. cælata*, *C. vasiformis*. *C. turbinata*, and *C. strobilocarpa*: and all of these are seen to be of distinctive Tertiary affinities.

In view of the fact that the traps near Rajahmundry must be considered as belonging to the lowest division of the Deccan traps as a whole, the two palæobotanical evidences we have cited above appear to be definitely in support of Dr. Sahni's suggestion that the Deccan trap flows are of an early Tertiary age.

Phosphatases of the Brain.

Two phosphatases, distinguished as acid and alkaline phosphatases and characterised by differences in optimal p_H are known to occur together in certain organs of the body. Thus, liver, kidney (Bamann and Riedel[1]) and spleen (Davies[2]) contain the two phosphatases. On the other hand, bone, intestines, blood plasma and erythrocytes contain only one type of the enzyme.

The phosphatases of the brain have not been investigated from this point of view. The present note relates to the presence and behaviour of two phosphatases in the brain (of the sheep). The alkaline phosphatase has an optimal reaction of p_H 9·6, and is activated by magnesium ions, the increases in activity exceeding 100 per cent. when magnesium is added in optimal quantities (0·001 M—0·002 M); the acid phosphatase which has an optimal reaction of p_H 5·0 is not activated by magnesium and resembles the urine[3] and salivary[4] phosphatases. The two phosphatases of the brain are thus similar to those of the other organs, in their behaviour towards magnesium.

Waldschmidt-Leitz and Nonnenbruch[5] consider that the alkaline phosphatase is typical for all organs; they suggest that the acid phosphatase demonstrated by Bamann and Riedel[1] is really due to the presence of erythrocytes in their extracts. This, however, appears to be untenable because the erythrocyte phosphatase is activated by magnesium salts, while the acid phosphatase extracted from the brain and the organs is not so activated.

Further work on the phosphatases of the brain is in progress.

A Note on the Jassid Bugs of Paddy.*

Introduction.

PADDY (*Oryza sativa*) is subject to the attack of about three dozen insect pests of which eight or nine, such as the paddy stem borer (*Schœnobius incertellus*, W.), the paddy swarming caterpillar (*Spodoptera mauritia*, B.), the rice bug (*Leptocorisa acuta*, Th.), the rice grasshopper (*Hieroglyphus banian*, F.), the rice case-worm (*Nymphula depunctalis*, Gr.), the paddy gall-fly (*Pachydiplosis oryzæ*, W.), the rice Hispa and Leptispa, are major pests. The Jassid bugs of paddy, however, come under the group of minor pests. Normally they do not do much harm to the plant but, in certain years, cause fairly serious damage.

Jassids—What these are.

Jassids are plant bugs belonging to the sub-order *Homoptera*, order Rhynchota. These have sucking type of mouth parts and two pairs of wings. They have an incomplete metamorphosis. Eggs are laid on the tender portions of the plant and the young ones which hatch out—nymphs—and also the adult bugs suck the juice of the plants and, if found in large numbers, the affected portions fade and dry up as a result of the attack.

Species of Jassids affecting Paddy.

Four species have been known to affect paddy in the Madras Presidency. These are the green-spotted Jassid (*Nephotettix bipunctatus*, F.); the white Jassid (*Tettigoniel spectra*, D.); *Erythroneura subrufa*, M., and *Deltocephalus dorsalis*, M. Of these, the first two are found in almost all paddy areas while the third one is commonly noticed in North Malabar and the last in the Northern Circars.

Control Methods.

Collection of nymphs and adults with hand-nets or bags have been found to be successful against the pest. The use of sticky winnows is yet another method advocated in some places. Light traps have also been tried especially against the green-spotted Jassid. The use of tobacco dust mixed with lime has given successful results against nymphs.

* In view of the recent outbreak of *Jassid* pest of paddy in Godavari delta, this account given by Mr. C. Cherian will be of interest (Ed.).

A Note on the Locust Position in North-West India and Baluchistan during the Current Year—1935.

EXPERIENCE gained during the last three years has shown that the multiplication of the Desert locust is entirely dependent on favourable rainfall in its breeding areas. During the winter and spring of 1934–35, early, wide-spread and heavy rains were received throughout the winter-rainfall areas of Baluchistan and Persia, and many of the coastal areas, such as Jask, Gwadar, Pasni and Ormara, recorded more than 10 inches of rain between December 1934 and April 1935. In the wake of such favourable rainfall, the locust was noticed to begin egg-laying early in February, and by April 1935 adult locusts of the new generation were found to have come into existence in fairly large numbers.

In the hinterland of Mekran, two cases of damage to *Jowari* crops by bands of gregarious hoppers were reported in June and July respectively, and on investigation, it appeared as if the hoppers had come into existence as a result of concentrated egg-laying in the sandy areas close by, by individuals of the first generation, that had been produced in the coastal areas and had, later on, migrated into the interior of Mekran. The adult locusts emerging from the infestations mentioned above are reported to have disappeared after acquiring wings. Since the interior of Mekran becomes an area of high temperatures and low humidity during July, August and September, it is presumed that they flee from such uncongenial conditions in search of better environmental conditions elsewhere.

By about the second week of July, a sudden increment in the numbers of locusts was noticed in several different places almost simultaneously: for example, at

Pasni, Gwadar, Ormara and Sonmiani along the Mekran Coast, in a large number of places in Sind, especially in Dadu, Sukkur, Hyderabad, Karachi and Tharparkar Districts, in Nushki and Kachhi in Upper Baluchistan, in the Khairpur and Bahawalpore States, and in many parts of Marwar, Jaisalmer and Bikaner States. In most cases, the incursion appears to have occurred as an imperceptible immigration of individuals, though in a few places swarms of small size were also reported. It is also noteworthy that a great proportion of the locusts collected after this incursion was found, on biometrical analysis, to show elytron-femur ratios pertaining to the *transiens* and *gregar* types, whereas the individuals found before this event in Sind and Rajputana deserts were mostly of the *solitaria* facies.

There was general rainfall in Western Rajputana and in the Thar portion of Sind during July, and oviposition by locusts was noticed to some extent in these areas in July and August, but during August and September rainfall was greatly restricted. On the other hand, in most parts of Sind and Baluchistan subject to the influence of the monsoon, there was a complete failure of rains, and consequently there was no breeding.

The new generation of locusts made their appearance in September in the desert areas of Sind and Rajputana, but though widely scattered over a large area of desert, locusts were found on the whole to be in comparatively small numbers. Their biometrical ratios, moreover, were noticed to be mostly of the *solitaria* type. Observations made so far appear to indicate that this year's incursion—presumably from a western source—has fizzled out and that at present there is no ground for anticipating the formation of swarms.

During the year 1926, a similar incursion, though presumably of a greater magnitude, occurred at about the same time of the year, and as a result of very heavy summer rainfall throughout Baluchistan, Sind and Rajputana, the resultant breeding was so extensive as to start the last great Locust Cycle of 1926–31. One wonders what might have happened if the current season's monsoon had been heavier and more prolonged.

Obituary.

Major Robert Ferguson Stirling (1886—1935).

IT is with deep regret that we have to announce the death, from heart failure on 16th August last at Nagpur, of Major Robert Ferguson Stirling, Director of Veterinary Services, Central Provinces. By his death at the early age of 48, India has lost one of the pioneer Veterinary workers in this country.

Born in 1886, he qualified with distinction as Member of the Royal College of Veterinary Surgeons from the Dublin Veterinary College. Soon after, he accepted an appointment in the Rhodesian Veterinary Service where he lay the foundations for his future interest in tropical diseases of animals. In fact, his thesis for his Fellowship of the R.C.V.S., which he took in 1912, was on the control of East-Coast Fever of cattle.

On the outbreak of the Great War, he joined the Royal Army Veterinary Corps and found active service in France. His army service called for high praise from his superior officers and particularly from Major-General Sir John Moore, K.C.M.G., etc., the then officer commanding the Veterinary personnel of the British Expeditionary Force in France. An appreciation of the late Major Stirling's work published in the *Veterinary Record*, London, by Sir John, is read with pleasure by many of the friends and colleagues of the deceased officer.

He joined the Civil Veterinary Department in C.P. in April 1920 and except for a short break when he was called on to officiate as Pathologist at the Imperial Institute of Veterinary Research, Muktesar, he continued to be in C.P. first as Deputy Director and subsequently as Director of Veterinary Services, C.P. In the latter capacity for well over seven years, he brought into his work scientific and organising capacity of a high order which had been the pride and envy of his colleagues and friends.

His scientific talents which found early vent in the study of East-Coast Fever in cattle, later developed with the limited opportunities for an administrative officer

in this country to the detection of Ranikhet disease in Fowls and the treatment of *Piroplasma gibsoni* in dogs and *P. bovis* in cattle.

His greatest achievement in Science, however, is his work on Rinderpest in cattle and its control. The first two progress reports on this work which appeared in scientific journals were well received by Veterinary workers all over the world and the third and final report which was almost ready for publication, at about the time of his death, will, it is hoped, be published in due course.

Personally Major Stirling was a most amiable man and made many friends amongst Indians. He was further able to induce a great deal of his enthusiasm for work amongst his co-workers and subordinates and to further this object, founded the C.P. Veterinary Association with its own *Quarterly Journal*. The latter had been the means of stimulating the subordinate Veterinary workers into expressing in accurate language the results of their observations of obscure diseases in the field. His energy for work was unbounded and he hardly restricted himself to the prescribed hours for office work. His end was very unexpected. To Mrs. Stirling who was on a holiday in England when the sad event took place and who was all through the late Major's career more than a helpmate to him and to mother Mrs. Stirling, we offer our sincerest condolences.

R. V. P.

Provash Chandra Basu.

THE sudden death of Mr. Provash Chandra Basu, M.B., M.SC., P.R.S., at the early age of 31 years on Friday, the 6th of September, has cut off a brilliant career at its very outset. Mr. Basu was a very distinguished student, and carried on his studies simultaneously in the Medical College whence he obtained the M.B. degree, and in Anthropology in the Calcutta University for which he was awarded the M.Sc. degree and later the greatly coveted Premchand Roychand Research Studentship. Both in the University and in the Medical College his career was exceptionally brilliant and he was awarded a number of scholarships, medals and prizes. Later, he was also selected by the Government of Bengal for a research scholarship for anthropological and ethnological studies; during the period of this studentship he carried out his work in the Anthropological section of the Indian Museum under the supervision of Dr. B. S. Guha. He was then appointed a research scholar of the Bose Institute, Calcutta and was attached to this institution till his sudden death.

Mr. Basu, as a result of his medical education, was specially suited for detailed anthropological studies and published several papers of importance in the *Journal of the Asiatic Society of Bengal* and in the *Transactions of the Bose Research Institute*, Calcutta. He also collaborated with Dr. B. S. Guha of the Zoological Survey of India in a publication in the *Anthropological Bulletins* issued by the Department, on the human relics recovered from the Naga Hills by the Expedition which was sent in 1926–27 for the abolition of human sacrifice. Special attention may be directed to his work on the Bhuiyas of Maurbhanj, the Racial affinities of the Mundas, and the so-called Pre-Dravidian tribes of India, while his studies on the Anthropological Measurements of the Mundas and Oraons also deserve special mention. In addition, he carried out detailed studies on Burmese crania and collaborated with Dr. Guha in his studies on the prehistoric human remains excavated at Mohenjodaro.

Mr. Basu's early death has unfortunately resulted in leaving his anthropological studies incomplete, but it is hoped that the work which he had so well started at the Bose Institute will be continued.

* * *

Edgar Thurston.

WE regret to record the death early in October when about eighty years old, of Mr. Edgar Thurston, well known as Superintendent of the Madras Government Museum for about twenty-five years, and as the author of *Castes and Tribes of Southern India*, the seven volumes of which, appearing in 1909, laid the foundations of ethnological research in South India.

Thurston was born in 1855 and educated at Eton and in the medical school of King's College, London. He was for some time in charge of the museum of that college, and came to India to take charge of the Madras Museum in October 1885 as its first full-time Superintendent. He seems to have found this Museum in a somewhat chaotic condition, without any very definite policy or aims, a state of affairs which he at once set himself to rectify. For we read in his first Annual Report, "It is wholly beyond the power or scope of a presidential museum to rival the great national museums in the possession of representative collections from different quarters of the globe, and I have

determined to devote my entire attention to the natural history, arts, ethnology, manufactures and raw products of Southern India, accepting only such specimens from other regions as may be sent as donations from time to time, and keeping them entirely apart from the main collections. The necessity for such a course is best illustrated by reference to the geological collections which, while abounding in a chaos of purchased and exchanged specimens of European fossils, is markedly deficient in specimens from the rich fossiliferous beds of the cretaceous system of Southern India." The policy which he thus established proved to be a sound one and, having been steadily pursued ever since, has resulted in the formation of the valuable South Indian collections for which the Museum is now known.

His wide interests and knowledge are indicated by the variety of subjects on which he wrote. These include coins, South Indian batrachians, fisheries and meteorites, as well as a number of papers on Anthropology; and under his guidance all sections of the Museum underwent great development, and the Connemara Public Library was founded with the Museum Library as its nucleus.

From September 1891 to November 1893, he officiated as Reporter on Economic Products to the Government of India in Calcutta. After his return to Madras he was appointed Lecturer in Comparative Anatomy at the Medical College for the year 1895-96, in addition to his permanent appointment. In 1901 he was similarly appointed Superintendent of the Ethnographic Survey of the Madras Presidency, which post he held till its termination in 1909. He finally retired in July 1910, but was absent on leave for some time prior to this.

* * *

Henry Fairfield Osborn.

WE regret to announce the death, at the age of 78, of Henry Fairfied Osborn, the eminent Palæontologist, well known for numerous publications, among which may be mentioned, "The Age of Mammals" (1911), "Huxley and Education" (1920), "Men of the Old Stone Age" (1915), "Origin and Evolution of Life" (1917).

Industrial Outlook.

Some Lines of Development of the Indian Paint Industry.

By N. Srinivasan, M.A.,
Department of Biochemistry, Indian Institute of Science, Bangalore.

THERE can be no doubt that the production of paint materials is a promising branch of Indian Industry. Its rise has been rather late; barely three decades have passed since it was initiated in the country. The first need of the industry in which practice has out-stripped theory, was a human one: experienced technicians. The second was special plant and machinery which constitute an important element in its establishment. These could not be met.

The advantages possessed by the Indian Industry, however, are many and obvious. It is well supplied with raw materials. It can depend on a large domestic market. Indian manufacturers could experiment under actual conditions to which they can adapt their processes. The creation of confidence in Indian manufactures, noticeable in recent times, is no small comfort to the industry. The Paint trade thus offers a great field of interesting possibilities for future accomplishment. It is true that, like many others, it has been through the trough of depression. But we are told there are indications of a return to a better trade. The new trend of industrial policy of the government is another healthy sign. The importance of technical research as a necessary aid to industrial progress has been realised since the days of the Holland Commission. The co-ordination of efforts in this direction under a unified control has also been very recently secured. With the establishment of a Central Industrial Research and Intelligence Bureau, might be said to begin a new chapter in Indian industrial development.

It may therefore be pertinent to take stock of what progress has been achieved in this particular branch; and indicate or reiterate those future lines of development which might yield to immediate enterprise and research. A detailed review of the

subject is not made. What is attempted is a selection for consideration of a variety of points. These have a general or particular interest when viewed from the following aspects:—(1) The Indian market for Paint products; (2) The natural resources available for exploitation; (3) The present state of technical efficiency in the country.

First take the raw materials. Among Paint vehicles the most important are Linseed and Tung oils. The position with regard to Linseed is strong. As for the other, great expansion is necessary to free the industry from Chinese supplies which are of bad quality and often adulterated. China wood oil possesses some unique properties and is an essential material in present day varnish making. Its ability to dry quick and its compatibility with synthetic resins are being exploited to best advantage. Another important property is its suitability for use with Rosin with which it gives the so-called Spar varnishes. This is of particular interest to the Indian Industry as Rosin is almost the only oleo-varnish gum available in the country. Rosin has hitherto not found favour as a good varnish-making material.

Experimental growing of Tung trees have been undertaken. It was found that the trees do well on Tea estates especially in Assam and Burma. The methods of cultivation of the plant in China are obscure. Systematic research in this aspect remains to be carried out; the soil conditions and methods of culture as affecting the yield of crop and processes of extraction and refining as influencing the quality of the oil. These studies would be of immediate value to the industry in its present endeavour to produce on an economic basis, oil of satisfactory quality. Trials of cultivation could be extended to other areas in the country.

Pigments play by far the most important rôle in Paint production. These could be classified under two heads, natural and chemical. The manufacture of pigments has mostly been undertaken by big Paint concerns for their use. The small consumer has hitherto been dependent on imports and these run high. The development of this line has attractive possibilities as pigments are used in other industries as well.

Among natural pigments, Barytes has a definite place in the stock of raw materials for the trade. The deposits in the Ceded Districts of the Madras Presidency and in Alwar are only too well known. Mainly through lack of initiative the available resources have remained unexploited. No export market can be found for the crude material. The extension of mining operations and the production of the material in various grades in a finely powdered form are most needed. That would destroy dependence on imports which still amount to more than half the consumption.

Lithopone is a chemically prepared white pigment which has assumed interest in recent times. Its advantages are many: excellent colour, great opacity, unique covering power, complete inertness and above all comparative cheapness. To-day its consumption rivals that of white lead. The production of this pigment which has yet to be undertaken in the country is important for the following reasons: It would stimulate mining to a larger extent, of the available deposits of barytes which constitutes the starting material for the manufacture of the pigment. The production of a variety of cheap paints with a Barytes-Lithopone base, particularly for the Indian market, remains to be carefully investigated. The recent tendency is to substitute the zinc oxide in enamels more and more by Lithopone and there is no prospect of the production of the oxide in the country. The complete absence of deposits of whiting—the base for the different types of water paints—would necessitate the substitution of Lithopone. Its unique opacity and covering power render possible its use in conjunction with large proportions of colloidal clay. Good white qualities of this material are forthcoming from different parts of the country. Lastly, mention might be made of the capacity of Lithopone to go with shellac varnishes to yield varnish paints which have special applications.

Lithopone is the mixed precipitate obtained by double decomposition of Barium Sulphide with Zinc Sulphate. Barium Sulphide could be produced by reduction of Barytes. As for the Zinc salt, one has to look elsewhere. It has been suggested that the blende from the Bawdwin mines of Burma can serve as raw material. In any scheme for the manufacture of the pigment there are two directions in which attention ought to be focussed: (1) The conditions of treatment of the precipitate so as to develop proper pigmentary properties. (2) The elimination of impurities for obtaining a light resistant material. Only then is standard Lithopone of commercial value possible.

Two other important whites are white lead and zinc oxide, the invariable constituents of exterior oil paints and enamels respectively. The raw material for their manufacture is again the mixed sulphide from Burma. White lead of satisfactory quality is being produced in the country from Burma lead by the precipitation process. There is no reason why production should not be increased. The outlook with regard to zinc oxide production by the direct process is discouraging. But the American method of preparation of cheap compositions containing basic lead sulphate and zinc oxide, straight from the mixed ore is deserving of careful consideration by the Indian Industry.

The greatest achievement in the line of white pigments has been the introduction of a white derived from Titanium. Almost a Laboratory curiosity some years back, to-day it is a bulk commodity with an annual output of 1,50,000 tons. Its strength, obliterating power, non-poisonous nature, complete inertness and above all versatility opened up entirely new fields for the industry. The raw material used is Ilmenite sand, of which the home reserves are estimated at 75 million tons. The export of the ore from Travancore began in 1922 and has expanded continuously. Attempts have yet to be made for utilising the same in the country. The process is well known. Present research must seek to eliminate impurities and elucidate the precise conditions under which the oxide develops proper pigmentary value. What is further needed is enterprise for starting a large modern plant with careful scientific control and intelligent commercial direction.

Passing on to the coloured pigments the most common are the earth colours. Red oxides of iron and yellow ochres of very good quality are available in the country and their production is continually on the increase. Umber and Sienna, which are of greater value are, however, surprisingly absent. These natural colours have the great advantage of being cheap. But they are available in very few shades. They lack brilliancy, uniformity and high staining power.

The artificial oxides of iron answer the demands of the industry for a better class of pigment materials. Their manufacture could be controlled and standardised. They are in addition much cleaner, possess better body and a finer texture. The synthetic oxides could further be used to tint natural ochres of low grade to improve their staining power. Their methods of preparation fall under two heads, the dry and the precipitation methods. In the dry method, ferruginous materials are calcined under controlled conditions. Precipitated hydroxide of iron is subject to treatments in the second method. Their manufacture merits enquiry. Although an attempt has been made in this direction, a great deal of work has to be done before standard shades of suitable quality are turned out.

The average consumer in most cases is content to buy dry colours and prepare the paint himself. The importance of their manufacture is thus easily realised. Many of the important pigments like Red lead, Prussianblue, Lead chromes, Brunswick green, and chromic oxide green whose manufactures have been attempted, call for increased production and great improvement in quality. The production of blacks of good staining power; cheap alkali resistant blues of the ultramarine type; organic Lake colours fast to light from coal tar dyes—these are lines which if pursued would confer great benefit on the industry.

The finished products of the Paint trade fall under one or other of the following classes: water paints; oil paints; lacquers, varnishes and varnish paints; Anti-corrosion paints; Enamels; Pyroxylin compositions and Synthetic finishes. From the point of view of the Indian Industry it may be useful to consider them under the following heads: (1) Those in which considerable progress has already been made. (2) Those which offer great scope for trial, experimentation and improvement. (3) Those in which there is little prospect of immediate commercial success.

Water paints, oil paints, lacquers, Spirit varnishes and Anti-corrosive compositions come under the first category. Among decorative paints, those thinned with water are the cheapest and deservedly popular. An ideal water paint should not rub off from the surface and withstand washing by water. It must be in dry powder form and miscible with cold water. Most of the commercial brands fall far short of this standard. It has been shown by the author[1] that highly satisfactory products could be obtained by using as binding medium a vegetable protein,—carbohydrate complex and as base, better grades of colloidal

---

[1] Ind. Pat. No. 20192, 1933.

clays with comparatively small proportions of Lithopone. These have the further advantage of being perfectly non-smelling during application or drying.

Emulsion Paints have always been of interest to the industry. Opinion is undivided as regards their future. The most practicable among them for the Indian market would be the Linseed oil—water-type. The author has succeeded in preparing compositions, suitable for application to wood or metal. These contain boiled or treated Linseed oil medium to the extent of 50% of the water vehicle. The base is Lithopone reduced with Barytes. Zinc oxide is added in some cases in small proportions. The size is a protein—modified cellulose mixture, prepared straight away from indigenous vegetable sources by simple methods.[2] The paint is produced as a stiff paste and softens readily when thinned with water before application. It flows nicely under the brush, covers well and is waterproof.

Such a paint could be obtained cheap and is of importance therefore under present economic conditions. The thinning medium is entirely water. No special costly emulsifier is employed. The size which is formed as a precipitate during preparation is used wet and serves to emulsify the oil and bind the pigments to the surface. Colours, many of which result in wet methods, could be incorporated as such and their drying costs obviated. It must be admitted that as regards weathering properties, a regular oil paint scores over the emulsion one. But it is not always that a complete destruction of the paint film is awaited, for repainting to be undertaken. More often there is a liking for change of colour. The ease of making and brushing of the emulsion paint renders possible to finish the painting with greater despatch and thus save in time and labour. It is not unlikely that it is more economical than the ordinary type, when durability per unit of price is taken into account. Further it dries quick and can be applied even in unfavourable weather. It is non-smelling while applying and leaves little lingering odour. These are highly desirable features particularly in house painting where a minimum of inconvenience to the occupants would be desired. The emulsion paint imparts a pleasing and restful eggshell effect, which in recent times has preference over a bright gloss. The surface however lends itself to further varnishing if desired.

Oil paints have made considerable headway in the country, as their formulation is devoid of much technique. They are produced by grinding together a pigment or mixture of pigments with oil, adding driers and thinning suitably. A great impetus to manufacture has however been afforded by improvements of plant technique. The result has been the introduction of ready-to-use paints of great convenience to the consumer. To-day the demand is for a quick-drying paint and this can be met by many an expensive synthetic finish. Present efforts could therefore be largely directed towards methods of treatment of Linseed oil so as to endow it with quick-setting properties without sacrifice of durability, brushing and storage qualities.

The use of shellac in the industry has received considerable attention for some time. It is a subject in itself, of great importance as lac is a virtual Indian monopoly. Among the products, that in general use is French polish, a varnish for woodwork made up from shellac, a soft resin and methylated spirits. Spirit varnishes yield, with aniline dyes in alcoholic solution, coloured lacquers useful for wood, metal or leather goods. These varnishes could also be incorporated with pigments for production of glossy paints possessing quick drying properties. By far the largest consumption, however, is as Insulation varnish for application in the electrical industry.

In many of these directions lac is threatened by competition from synthetic substitutes. Being laboratory products, their supplies are regular, prices dependable, trade organised and above all, quality uniform. Their properties, largely under scientific control, could be varied to adapt them for purposes on hand. Research measures that have been adopted to resuscitate the Indian trade in lac are directed towards better production and improved manufacture. The aspect of improvement of the quality and quantity of lac has been carried out at the Research Institute at Namkum. More recently the technical side has come in for consideration. It embraces an extended study of the physico-chemical properties of lac, which largely determine its value; devising of methods to rectify the weaknesses of lac so as to meet the needs of the consuming industries; and finally,

---

[2] Ind. Pat. No. 20143, 1933.

exploring of new avenues for its applications. The close association of the industries, concerned in these studies, is a factor of no mean significance. The results will be watched with interest even by those who wish to preserve the field for demand of the material within the country.

Special paints for protection of iron work are made in large quantities and used. Mention might be made of oxide of iron and red lead paints and the more recent ones containing a metallic pigment like aluminium. Considerable attention has been devoted to the production of bituminous compositions for which sometimes extravagant claims are made. Many of them are compounded from Asphaltum, one or other of the artificial pitches and Linseed oil treated with Litharge, red-lead and a varnish-making gum. The thinner is usually turpentine.

High grade oleo-resin varnishes which would suit actual conditions, are still products of future manufacture. Progress in the line has been inconsiderable as their production is an art in which empiricism is the sole dictator. A varnish is obtained by cooking a drying oil like Linseed, with a varnish-making gum, adding proper driers and thinning. Experience alone can guide in the choice of ingredients and their manipulation, factors which decide the quality of the final product. The raw materials except the resin are found in the country. Success must depend therefore on patient formulations and practical trials.

Specially compounded varnishes serve as media for Enamels. These dry quick and give hard and durable surfaces with permanent gloss. The colours and pigments therein are in a much finer state of division than in ordinary Paints. An enamel which does not thicken and is satisfactory in several respects, can only result from a proper choice of the pigments for incorporation into the media whose preparation is as important. The field is open and offers ample recompense for adequate experimentation.

Synthetic and Pyroxylin finishes are infants in the trade. Though their production in Western countries rivals that of other materials, they are only of subordinate importance in the Indian industry. The Synthetic finishes are based on the manufacture of artificial resins, which could be dissolved in suitable solvents to yield media for paint varnish or enamel. What is aimed here is improvement over the natural products, with regard to adhesion, durability and gloss retention.

Pyroxylin finishes contain as media, low viscosity solutions of cellulose nitrate in various organic solvents together with a plasticiser like castor oil or triphenyl phosphate to render the film flexible. They could be coloured to form lacquers, combined with resins to produce varnishes and incorporated with pigments to give enamel paints.

A great drawback to the use of the above two modern finishes is their expense and as a consequence, only a very limited market could be found for them. The problem of the solvents for use—many new ones have been introduced—has yet to be successfully solved by the Indian industry. Further their production calls for special technical skill of a high order. Their manufacture in the country may not therefore be assured of a welcome for some time to come.

"Vernalizing" and Crop Yields.

MR. T. Lisenko, the Russian scientist, announced before the recent Conference of the Soviet Academy of Agricultural Sciences, the results obtained by *vernalizing* a new process for seed regeneration possessing great potentialities for increasing crop yields and insuring against crop failures. The method which is applicable to all self-pollinating plants is to take the pollen from 100 to 200 plants of the same variety, mixing it with a brush and then dropping the mixed pollen into the flowers after bending back the petal-scale with pincers. The seeds obtained are first moistened and then submitted to different degrees of heat before sowing. By this simple process it is possible to obtain plants better adopted to the region than their parents. *Vernalized* wheat matures 3 to 7 days earlier than untreated seed; the treated seed also sprouts earlier. 1,500,000 acres in the Kuibesheff (Samara) Province have been planted with *vernalized* wheat and 1,000,000 acres in the Ukraine Province. In the latter Province, 3,000 acres were planted with *vernalized* cotton seed and the results were, in all cases, satisfactory—the crops developed earlier and the yields were higher as compared with untreated seed.

Research Notes.

The Relation of the Splitting to the Field Strength in the Zeeman Effect of Some Mercury Lines.

THE successful production of high magnetic fields by Kapitza has given rise to new and interesting problems. One of these is the behaviour of the Zeeman pattern of spectral lines in these high fields. Kapitza and Skinner found that in the case of λ 4047 ($^3P_0 - {}^3S_1$) of mercury the separation between the Zeeman components increased more rapidly than the field. Now G. Dupouy and P. Jacquinot (*Comptes Rendus*, 1935, **201**, 543) have studied the behaviour of $\lambda\lambda$ 5461, 4358 and 4047 ($^3P_{2,1,0} - {}^3S_1$) in fields up to 50,000 gauss produced by the large Bellevue magnet. They found that the patterns of 5461 and 4358 were not of similar constitution at different fields. Thus the theoretical pattern of 4358 is $\frac{(1),\ 3,\ 4.}{2}$ The authors now find that the separation between $\pm 3/2$ is proportional to the field strength while that between ± 2 increases more rapidly than the field. Hence they conclude that the separation of the $^3P_1$ level is strictly proportional to the field while that of $^3P_2$ and $^3S_1$ is not. Another interesting point is that the ratio of the splitting of $^3P_2$ and $^3S_1$ is constant. The effect thus found is not connected with the Paschen-Back effect since the fine separation of the mercury triplets is very large. The influence of high order terms in the Larmor precession cannot be a possible explanation since the separation of $^3P_1$ is proportional to the field. The anomaly is thus unexplained.

Observation of the Brownian Motion with the Unaided Eye.

THE observation of Brownian movement with the unaided eye has recently been considered in a number of papers. The phenomenon observed is a lively shimmering with colour variations seen when a concentrated sol of rosin or solution of gamboge placed between two glass plates is irradiated by strong light from a point source and observed by means of the light it scatters. The eye is to be focussed on the sol. There has been some controversy as to whether the phenomenon is really due to Brownian motion, but E. Kappler (*Physikal. Zeit.*, 1935, **36**, 643) now put forward some reasons for believing that what is seen is really the effect of Brownian motion. Considering two surface elements which are just seen separate by the eye, the brightness and colour of these vary as the concentration of the layer varies on account of the Brownian motion and the diffraction and interference phenomena due to the particles in these surface elements alter. This alteration of brightness and colour gives a sensation of irregular motion. That interference is the cause of the observed colour and light variation is seen from the fact that the sol must be irradiated by a point source while diffuse illumination makes the solution appear uniformly bright. The effect is not visible in or near the direction of the incident rays. The particles of gamboge have to be sufficiently near, that is, a fairly concentrated solution is necessary. When the solution is observed with a microscope with large aperture the ordinary Brownian motion of the particles is observed, the particles appearing dark on a bright background in direct light and as bright points on a dark background in scattered light. In scattered light we find an entirely different appearance when the aperture of the microscope is small. The several particles are no longer seen separate but the light coming from different layers shows a lively variation of colour and brightness. An explanation of these phenomena in terms of Abbé's theory of the image formation by non-self-luminous substances is given in the original paper.

T. S. S.

Use of Direct Current in the Measurement of Electrolytic Conductance.

BRONSTED AND NIELSEN (*Trans. Far. Soc.*, 1935, **31**, 1478) have pointed out the advantages of using direct current in the determination of conductivities of solutions. A simple apparatus is described involving the use of two lightly platinised electrodes which are rendered non-polarisable by bubbling hydrogen through them. This is found to be particularly suitable for the measurement of conductivities of acids and bases. The method described should be of immense use in the measurement of high resistance systems, where the usual alternating current method is not so satisfactory.

M. P. V.

Electrometric Estimation of Traces of Chloride.

THE usual nephelometric procedure for the estimation of traces of chloride present as impurity in reagents is not very satisfactory, as the presence of salts considerably affects the measurements. Furman and Low (*J. Amer. Chem. Soc.*, 1935, **57**, 1585) have described an electrometric method involving the use of silver-silver chloride electrode. A concentration cell is constructed wherein liquid junction is eliminated, by making the solutions into which the two silver-silver chloride electrodes dip identical except that one side of the cell has the chloride of unknown concentration x, and the other side $x + a$, when a is a known weight of chloride added to the solution under test. Traces of chloride of as low a concentration as ·00035 gr. of Cl^- per litre have been measured accurately by this method. This is of quite general applicability, and should be useful for other reversible electrode systems.

M. P. V.

Oil Formation in the Groundnut.

THE progress of oil formation in the groundnut has formed the subject of a study by J. S. Patel and C. R. Seshadri (*The Indian Journal of Agricultural Science*, Vol. V, Part II), who conclude that as the groundnut develops, the percentage of oil gradually increases except in the early stages immediately following blooming and the period just preceding maturity. There is throughout the development of the seed a gradual and uniform gain in oil content and reduction in the free fatty acid content. The harvest of the groundnuts even one week before the kernels are fully mature increases the quantity of free fatty acid and reduces the oil content by about five per cent. The high free fatty acid content in the groundnut reaching England from the Coromandel Coast ports and from Calicut which goes up as high as 11% and therefore reduces its quality and price very considerably, is surmised to be partly due to the practice of harvesting the groundnuts before they are fully mature. It is significant that Marmagoa and Bombay shipments which include the crop from the Mysore State are strikingly low in their fatty acid content being only about 2·5 per cent. at the most.

Photo-Oxidation of Sulphur.

EXPERIMENTS by Fazal-ud-Din (*The Indian Journal of Agricultural Science*, Vol. V, Part II) establish that elemental sulphur undergoes oxidation by mere exposure to light which thus becomes an additional agency to bacterial and chemical oxidation. The photo-oxidation is also found to be greater in the presence of certain catalysts such as zinc oxide, animal charcoal, and soil, the action due to zinc oxide being however negligible when compared with the other two. In these latter, the oxidation proceeded even further when light was excluded. In an alkaline medium the oxidation was slightly higher. In soils rendered sterile as regards sulphur oxidising bacteria, the photo-oxidation was very much slower than in soil not rendered sterile. It would be interesting to study the extent of the solubility of the phosphate in animal charcoal or bonemeal mixed with sulphur and treated in the most favourable manner for photo- and bacterial-oxidation of the sulphur.

Oxidation of Fats in Animal Tissues.

IN the course of two important papers appearing in the *Biochemical Journal* (1935, **29**, 2143–80), Jowett and Quastel have made a critical study of fat metabolism by employing an *in vitro* method, which takes advantage of the previous observation (Quastel and Wheatley, *Biochem. J.*, 1933, **27**, 1753) that fatty acids are oxidised at considerable rate by slices of liver, giving as one of their oxidation products acetoacetic acid as in the body; the acetoacetic acid is estimated by the manometric method of Warburg. A study of the kinetics of the oxidation of butyric, crotonic, β-hydroxy butyric acids by the liver of the Guinea pig, has shown that the rates of oxidation are in the order cited, being highest for butyric. The variation in the rate of oxidation coupled with the observations that propionate and cinnamate while inhibiting the oxidation of butyric and crotonic acids, possess no effect on the oxidation of β-hydroxy butyric acid, rules out the view previously held that the mechanism of oxidation of the three acids are interrelated. The view that β-hydroxy butyric acid is an intermediate product is also untenable; in fact the indications are that this acid is produced from acetoacetic acid. It is however probable that crotonate passes through

butyrate as an intermediary. It is even more probable that the process of oxidation to acetoacetate takes place after adsorption on the surface of one and the same enzyme which effects the complete process with both butyrate and crotonate.

In the second part, the authors have extended the studies to the oxidation of normal saturated fatty acids containing from 2 to 10 carbon atoms. In the first place, it has been shown that there is a relation between the increase in acetoacetic acid production and the increase in respiration brought about by the fatty acids, a relation which is characteristic for each acid. There is also a characteristic difference between the behaviour of acids with even and odd number of carbon atoms, the latter being more completely oxidised in the liver. Acetoacetic acid is probably the only β-ketoacid produced in significant quantities by the oxidation of fatty acids. The β-oxidation theory of Knoop is inadequate to explain all the observations quantitatively. The observation that benzoate strongly inhibits the production of ketonic bodies from butyrate, while the inhibition is less with higher fatty acids, suggests that butyric acid is not an intermediary in the breakdown of higer fatty acids as demanded by the theory of Knoop. The authors propose a "multiple alternate oxidation" theory according to which the fatty acids undergo, at a common enzyme, an oxidation throughout the fatty chain, alternate carbon atoms being affected. The oxidised product then breaks down, and the ultimate production of acetoacetic acid and other acid products. The theory is somewhat speculative, and further developments are keenly awaited.

Iron Gallate Inks—Liquid and Powder.

ZIMMERMAN (*Journal of Research of the National Bureau of Standards*, 1935, **15**, 35) describes experiments carried out with a view to prepare inks and ink powders which would not only satisfy the requirements of the U. S. Government Standard writing ink but at the same time be less corrosive on steel-pens.

The effect of gallic and tannic acids on the stability of inks was studied quantitatively by noting the period which elapsed before any sediment was observed.

The substitution of ferric sulphate for the ferrous sulphate in the preparation of ink was found to result in increased corrosive action on pens, but it was also found experimentally that addition of oxalic acid (about 3g/L) to ink so prepared, not only reduced its corrosive action considerbly, but also increased its stability. Oxalic acid, however, accelerates deterioration of paper, and so such ink is unsuitable for making permanent records.

Three '*formulas*' are suggested in a tabular form for the preparation of ink, either liquid or powder.

K. R. K.

Separation of Petroleum Hydrocarbons with Silica Gel.

IN a paper published in the *Journal of Research of the National Bureau of Standards* (1935, **15**, 51), Mair and White have presented the results obtained in a study of the efficiency of silica gel as an adsorbent of some types of petroleum hydrocarbons with a view to its application to the important problem of the separation, identification and determination of the constituents of petroleum.

Two grades of silica gel were employed, one being 40–200 mesh, and the other 200 mesh and finer. The silica gel was kept at the lower end of a glass tube and served as a bed through which the hydrocarbon mixture filtered at a predetermined rate.

Adsorption experiments with the following systems were performed: (1) mixtures of an aromatic and a naphthene or a paraffin hydrocarbon, (2) mixtures of a naphthane and a paraffin hydrocarbon, (3) petroleum distillate boiling between 140 and 145°·5 C.

The results of these experiments show (*a*) that there was a complete separation of the aromatic and olefin hydrocarbons from paraffin and naphthene hydrocarbons, (*b*) that the gel showed a tendency to adsorb the naphthenes in preference to the paraffins, (*c*) that there was a slight separation of normal paraffin hydrocarbons, the paraffin of low molecular weight being adsorbed in preference to that of high molecular weight.

It was also established that in none of the experiments carried out did the silica gel crack or otherwise attack any of the hydrocarbons employed.

A simple and efficient laboratory method (98 per cent. recovery) employing silica gel is suggested for the complete removal of aromatic from naphthene or paraffin hydrocarbons.

K. R. K.

Oogenesis of Acentrogobius Neilli.

M. K. SUBRAMANIAM AND R. GOPALA AIYAR have published the results of their investigations on the vitellogenetic activity in the ovum of Acentrogobius Neilli (*J. Roy. Micr. Soc.*, September 1935, **55**, Pt. 3) in which they record that the Golgi apparatus which makes its appearance in the young oocyte in the form of a single dense mass in the neighbourhood of the nucleus. Later the mass is seen to break up into a number of minute grains which migrate towards the periphery. Fatty yolk is formed from them. The mitochondria which are at first in the form of a circumnuclear ring later become dispersed. The authors are definitely of opinion that they do not take any part in deutoplasmogenesis. A nucleolar origin of fat is described. Even in the earliest stages the nucleoli are multiple and as growth proceeds they move towards the periphery of the nucleus. The authors have put forward the novel suggestion that even within the nuclear membrane the nucleoli become lipoid and while there is no evidence of their migration into the cytoplasm, presence of fat globules outside the nuclear membrane adjacent to the nucleoli which have now taken up a perinuclear position has been adduced as evidence for the nucleolar origin of fat.

A Hitherto Undescribed Piroplasm of Goats (*Piroplasma taylori*).

EARLIEST record of piroplasma in sheep was made in Roumania by Babes in 1892. Since then various workers have recorded the presence of piroplasma in the blood of sheep and goats. In India only two records are available—one from Muktesar among goats and the other from Mysore among sheep. Sarwar (*Indian J. Vet. Sci. and Anim. Husb.*, 1935, **5**, 171–176) has observed a piroplasm in goats which does not agree in any way with the description of the hitherto recorded species. Its morphological features are suggestive of its being a new one. The parasite was obtained during post-mortem examination on a goat.

The infected red blood corpuscles are distinctly enlarged in size proportionately with the number of parasites occupying them. The parasite divides into two or multiples of two at the same time. From 2 to 16 elements have been noticed in the red blood cells.

The author proposes the name "Piroplasma taylori" to the new species of piroplasm.

S. D. A.

Bovine Surra in India.

Indian cattle and buffaloes generally are found to possess a much higher degree of resistance to Surra than equines and they often harbour the parasites in their blood without evincing any evidence of disease. But some outbreaks have been noted in the Punjab and Hyderabad State where the disease has proved fatal to the animals.

Krishna Iyer and Sarwar (*Indian J. Vet. Sci. and Anim. Husb.*, 1935, **5**, 158–170) refer to an outbreak at the Imperial Cattle Farm, Karnal, where 12 animals were affected and 4 died out of 176 animals on the farm. The disease was observed to be more severe in bullocks and young male animals, whereas in cows, the disease appeared in a milder form, and none of the affected cows died.

Various drugs such as Atoxyl and Arsenic, Chiratta, Neem leaves, "Bayer 205", Tartar emetic and Naganol have been tried by various workers. The authors claim successful results by treating the affected with 10 to 30 c.c. of a 10 per cent. solution of "Bayer 205" intravenously.

The authors have discussed the transmission of Surra by invertebrate vectors. The abnormal contents of two Bdellolarynx flies were found to contain trypanasomes immediately after they had fed on infected animals.

T. evansi is the specific protozoa that caused Surra in this outbreak.

S. D. A.

Ciliates from Indian Mammals.

A NUMBER of papers on Ciliates Protozoa belonging to the family *Ophryoscolecidæ* have been published recently. Prof. C. A. Kofoid visited India as far back as 1916, and made a large series of preparations of Ciliates from *Bos indicus*, *Bos gaurus* and *Elephas indicus*. Those from *Bos indicus* have been exhaustively studied by Kofoid and MacLennan in a series of monographs (1930–33) which have been already noticed in this Journal *Curr. Sci.*, 1935, **4**, 13-16). Kofoid and Christenson (*Univ. Calif. Public. Zool.*, 1934, **39**) have described 25 species belonging to 8 genera from the stomach of the gaur. Of these, 11 species are the same as already

described from the Indian ox, and 9 species identical with those already recorded from domestic cattle, etc., in other parts of the world. Five species, *viz.*, *Entodinium contractum*, *E. curtum*, *Metadinium rotundatum*, *Ostracodinium mysorei*, and *O. gauri* are new to science. These Ciliates from the wild relict member of the ox tribe show no primitive characteristics, being as complex in their evolutionary tendencies as those from other domesticated ruminants. The two species described by Kofoid (*Proc. Nat. Acad. Sci., Washington*, 1935, **21**) from the cæcum and colon of the elephant are very remarkable indeed. *Polydinium mysoreum* and *Elephantophilus zeta* not only belong to new genera, but have to be placed in a new subfamily. In other genera of *Ophryoscolecidæ*, known so far, there is either the adoral zone of membranelles only present, or a second dorsal zone in addition. The members of the new sub-family, *Polydiniidæ*, are characterised by the presence of numerous accessory membranelle zones extending over the considerably elongated body. These zones instead of being dorsal are divided bilaterally in two groups, and thus a secondary bilateral symmetry is superposed upon the primitive spiral one.

M. Das-Gupta from the Department of Zoology, Calcutta University, has published an interesting record of Protozoa from the rumen of the goat, *Capra hircus* (*Arch. Protistenk., Jena*, 1935, **Bd. 85**). Besides 1 rhizopod and 6 flagellates, no less than 36 species belonging to 11 genera are recorded with brief notes. Of these latter, four are described as new species of *Entodinium* and 13 species belonging to several genera are believed by the author to be new records from the goat. What a wealth of material is at hand in such a common animal as the goat!

The Ciliates from the horse, sheep, and camel have not yet been studied in India so far.

B. L. B.

The Y-Granules in Insects.

SINCE the discovery in Saccocirrus of a group of granules allied microchemically to yolk, attempts have been made to find them in other animals and J. A. Muliyil's work, on a number of insects (*J. Roy. Micr. Soc.*, September 1935, **55**, Pt. 3) has revealed their existence. Most cases can be demonstrated by the employment of neutral red though this is by no means the most specific method. In a few cases, a single homogeneous body later breaks up to give rise to the characteristic granules. Evidently their function is not known and they are eventually cast out during spermateleosis.

Malpighian Tubules in Melanoplus.

R. R. STUART describes the structure of the malpighian tubules in the grasshopper Melanoplus (*J. Morph.*, 1935, **Bd. 58,** No. 1, p 173). There are about 192–312 malpighian tubules, collected into twelve bundles. Each bundle opens into an excretory ampulla. Each tubule is composed of large polygonal cells. The ampulla consists of an inner mass of unchitinised epithelium and a layer of chitinised cells. These two are separated by a narrow irregular lumen. The epithelium of the cephalic intestine is thrown into 12 long folds.

The Mineralogical Classification of Igneous Rocks: A Comparison of Recent Proposals.

IT is well known that the want of a standard method of classification of igneous rocks has rendered the task of many petrographers difficult, more so in recent times where each author favours his own type of classification. In comparing the mineralogical with other types of classification S. J. Shand (*Journal of Geology*, **43,** No. 6) has put forward a strong plea for evolving one common type of classification. Shortly reviewing the works of Iddings, Winchell, Holmes, Niggli and Grout, Shand has shown that there is a general tendency to accept two instead of three textural divisions as a basis for classification. With the increasing recognition of colour index, and the use of actual instead of calculated felspar, it is possible to develop a fairly comprehensive classification; and if leading petrographers come to an understanding on these points, it will be a great relief to many workers in their every-day work, leaving the other types of classification for specialists desiring to institute broad comparisons for purposes of regional geology.

The Fifth Congress of the International Society of Sugarcane Technologists.

The Meetings and Excursions.

THE above Congress met at Brisbane in Australia from the 27th August to 3rd September, 1935—the meetings being divided into various sections such as Agriculture, Breeding and Sugarcane Varieties, Methods of Field Experimentation, Sugarcane diseases and various aspects of the factory. The Congress was well represented, the members who answered the roll call hailing from all the important sugarcane countries of the world—Hawaii, Lousiana, Porto Rico, West Indies, Cuba, United States of America, Peru, South Africa, British India, Java and others.

The State Government of Queensland, the Commonwealth Government of Australia and the various sugar interests in Australia, all combined to make the delegates feel quite at home in that interesting country. At the end of the Congress meetings at Brisbane a special train took the delegates into the various plantations and sugar factories. This tour which lasted almost a fortnight was very interesting as bringing the delegates into close contact with a Sugar Industry which has certain very interesting features to the visitor from abroad.

THE SWEETEST CANES IN THE WORLD.

Australia is adjacent to New Guinea which is believed to have been the home of at least one race of the sugarcanes in cultivation and the dominant cane in cultivation in Australia to-day is Badila—one of the original types found in New Guinea. The breeding of new canes from seed has been in progress in Australia for some time and has resulted in types suited to special conditions; but in the best cane lands Badila still holds its own. This cane has been tried in various parts of India, but it has shown its usefulness only in one locality in South India—in the factory plantations at Nellikuppam.

Australia also grows the sweetest cane in the world and the sugar recoveries are higher than in most other countries due chiefly to the quality of raw material. The general trend of opinion at the Congress indicated the set of climatic conditions in Australia as the chief factor contributing to this superior quality. It was found that the same variety showed better juice quality in Australia than elsewhere. The Coimbatore cane—Co.290—which is proving useful in Australia chiefly on account of its marked resistance to the diseases common in Australia, shows better juice quality in Australia than in India.

CROP GROWN WITH 100% WHITE LABOUR.

But perhaps the greatest interest of the Australian industry to the visiting delegates lay in its being run on a "White Australia" policy and the adjustments arising out of it. At present only white labour is employed in the sugar factories and plantations. The standard of living in Australia is said to be higher than in most other countries and the white labourer in the sugar plantations in Australia is entitled by law to receive as wages 16 shillings (Australian) per day, which is almost equivalent to about half a month's wage in Java and India.

This has led to a marked development in labour-saving machinery and this was prominently brought to the notice of the delegates during the itinerary after the Congress meetings. From the time of planting—which itself is done by machinery—right to the harvest the machine does all the field operations including weeding after cultivation, application of fertilizers, etc. As to harvesting machinery, though one was demonstrated in one of the largest plantations, the mechanization of this part of the operation has not yet been a complete success.

A WELL-PLANNED INDUSTRY.

The whole industry in Australia is run on a thoroughly planned basis, which naturally involves control at various stages either by Government or Pseudo-official bodies like the Sugarcane Prices Board set up by Statute. The area from which the factory is to derive its supplies, the wages to be paid to the labourer, the working hours for labour —including a factory holiday on Sunday— the price to be paid to the cane and the rate at which sugar is to be sold in the country, are all fixed.

AUSTRALIAN SUGAR WELL PROTECTED.

It was certainly most interesting to learn that whereas the price of sugar per lb. in Australia was 4*d*., the same Australian sugar sold in the London markets fetched only about 1½*d*. Though Australia loses about £ 6 to 8 (Australian) on every ton of sugar exported, ample justification for maintaining the industry is found (i) in finding employment for the Australian white population and that too at a high standard of

living, (ii) in populating the rather vulnerable North Queensland, and (iii) in supplying the country with home-grown sugar.

The profits of the industry appeared to be better distributed than in most other countries and one marked feature was the fair number of factories owned by the growers themselves on a co-operative basis.

DIFFERENT STRAINS OF THE SAME DISEASE.

On the scientific side, discussions at the Congress brought out many points of interest. The papers presented indicated almost unmistakably the possible presence of different biological strains or pathogenic types of one and the same disease. This has an important bearing on the transport of new canes from one place to another and on the methods of disease-resistance trials.

USE OF *Saccharum Robustum* AS PARENT.

Saccharum officinarum when crossed with *Saccharum spontaneum* (male parent) doubles its chromosome on the mother side. No such doubling takes place when *S. officinarum* is crossed with *S. robustum*. This opens up a new line of work in Sugarcane Breeding so far at least as the tropical sugar world is concerned. Sugarcane breeding has gained greatly by the use of *S. spontaneum* as one of the parents. The use of *S. robustum* has not yet been exploited and there are indications from Hawaii that for Hawaii, at any rate, the use of *S. robustum* is likely to be useful. The delegates—including Dr. Brandes, the discoverer of *S. robustum*—saw in one of the Breeding Stations in Australia certain promising seedlings obtained from the mating with *S. robustum*.

MANY DISEASES KEPT UNDER FULL CONTROL

Similar interesting facts emerged from the discussions in the other Sections as well. But one fact which impressed the Congress as a whole was the very successful manner in which the various cane diseases had been controlled in Australia by suitable organization of control measures and growing resistant types. So efficiently has this been done that, though in the first circular it was mentioned that pathologists would have an opportunity to see many diseases, in the actual visits to the plantations it was difficult to get good specimens of the same.

The Congress was fortunate in having the presence of such a distinguished sugar-man as Dr. C. A. Browne, who was specially honoured by the Congress at its full session. The next Congress is to be in Louisiana in 1938 under the General Chairmanship of Dr. E. W. Brandes, the well-known head of the Bureau of Plant Introductions, United States of America.

The Shape and Size of the Earth.*

THE fundamental problem of geodesy is the accurate determination of the form of the Earth or the deviations of the actual geoid from the international ellipsoid and also study the dynamic causes that bring about a change in this form, the guiding principle being the principle of isostasy.

The problem of the determination of the form of the earth resolves into the following :—

(1) Observation of the mean levels of the sea ; therefore a study of the tides in the oceans at different places.

(2) Observation of the surface inequalities. This involves levellings to determine the height, etc., by means of spirit levels and telescopes.

(3) Determination of distances on the earth in different directions. This is done by a system of triangulations by means of chains of standard lengths made of invar to determine the distance of two stations along what is called a straight *base line*. A precision theodolite enables the position of a third station to be observed from the first two by noting from each the angular separation of the two other stations. This is extended through a large number of stations to those hundreds and thousands of miles distant. By assuming a mean form of the geoid the longitude and latitude (geophysical) could be measured with respect to a standard station, chosen centrally.

(4) Determination of the astronomical latitude by observation of the azimuths of two stars one on either side of the zenith, or vertical or plumb line, at the place of observation by means of telescopes.

(5) Determination of the astronomical longitude by observing the local time by the transit of stars over the meridian and simultaneously getting by means of accurately adjusted chronometers or time signals times

* The Survey of India, Geodetic Department, 1934.

from some place of reference whose longitude is assumed.

(6) Comparison of 4 and 5 with 3 gives an expression of the deviation of the plumb line, or of the direction of gravity from the vertical (the perpendicular to the international spheroid or whatever general geoid that fits best). This gives gravity level surfaces.

(7) The curvature of the plumb line measured by the torsion balance of Baron Ötvos. One type of this balance in which two equal weights are attached to the ends of a beam suspended at the middle with a quartz fibre gives the gradient of the gravity deflection along two directions. A second type in which one weight is above and the other equally below the beam enables the gradient to be measured in magnitude as well.

(8) Determination of the absolute intensity of gravitation at different places by means of pendulums.

(9) Determination of the intensity of gravity on sea, by means of a barometer to be read correct to 0·01 mm. and determination of boiling point of pure water to an accuracy of 0·001° C., in that with change of gravitational intensity alone the pressure read off remains the same, the boiling point however indicates the change.

(10) Purely astronomical measurements of the precession of the equinoxes. They enable the form of the earth to be calculated. If the earth were perfectly round, there would be no precession.

The determination of the accurate form is of utmost importance in the location of mineral resources such as ore, coal, oil, etc., even when hidden deep in the crust, because these minerals are pretty sharply distinguished from the rest of the crust by their density so that measurement of plumb line deflection gives the wanted clue. Almost every government has established departments of its own for such measurements. The Geodetic Branch of the Survey of India, Head Office Dehra Dun, is in charge of these measurements in India. The Survey of India is an old institution. The Great Trigonometrical Survey was started in 1800. From 1922 the annual reports are published in three separate volumes of octave size, *viz.*, (1) General Report which is confined to reporting the Survey operations of the ordinary field parties and detachments with only brief abstracts of Geodetic operations, and Map Publication and Office Work. Published annually. (2) The Map Publication and Office Work Report which contains all the Index Maps showing the progress of Map Publications on all scales, with reports on publications and issue. Published annually beginning with year 1924, price Rs. 3. (3) Geodetic Report which includes full details of all scientific work of the Geodetic Branch, Survey of India. From 1933 inclusive, the General and Map Publication and Office Work Reports have been confined into one report under the title of General Reports at Rs. 1–8–0.

Triangulation, levelling, gravity, deviation of the vertical and predictions of tides have been the main features of the Geodetic Reports of every year. Preparation for the international longitude project began in 1925–26 and was receiving the attention of the Department in years 1926–27 and 1934, magnetic measurements were made in 1925-26. In 1930–31, a Magnetic Survey was included. In the 1934 report (the latest) Chapter I, devoted to Triangulation and Base measurements, are given results of measurements of three base lines, one in Baluchistan, second in Poona and the third in Assam and the order of accuracy discussed (1 in about 600,000), the best hours for observation of the horizontal angles found to be either morning or evening. Levelling parties worked mostly in Burma and Northern Shan States. Late in the year three double detachments and eight single detachments were formed for levelling the Bihar Earthquake (Jan. 15, 1934) area. Bench marks showed shrinkages up to $4\frac{1}{2}$ feet and only four cases of elevations were observed of which the largest is 0·029 feet. The largest sinkages occurred in structures which had presumably sunk into the ground, and the embedded bench marks generally show smaller change although one case of 2·7 feet was observed.

Chapter III gives the results of pendulum experiments for the intensity of gravitational attraction in Ceylon, and in the Maldive and Laccadive islands. Gravity results of Ceylon show a satisfactory agreement with the geology. They suggest that the tilted syncline (folding in ellipsoidal, paraboloidal surfaces with same sign for the principal curvatures) of the island is unsymmetrical as it is distorted in the region of the Adam's Peak. In the Maldives evidence supports the theory that those coral islands are formed by gradual subsidence of the ocean bed due

to isostatic adjustment. Work at Minicoy leads to the interesting conclusion that the Laccadive islands are tectonically different from the Maldive islands.

Two detachments were employed on tracing sections of the geoid by means of stations at close intervals by observing both components of the deviation of the plumb line. One worked from Assam–Burma frontier through Bengal to Bihar. In 1934–35 it is expected to push this up to Agra and to observe in Sindh and Baluchistan. It is expected that by 1935–36 the whole section from Persia to Indo-China would be completed. The second detachment observed latitude only between Cape Comorin and Hyderabad (Deccan). The observations of the Siamese Survey have been made use of along with those of the Indian and the geoid calculated. The radius of curvature of the east-to-west section 2,500 miles long is 700 feet greater than that of the international spheroid, while the curvature of a 2,000 miles north-to-south section 1,500 feet less than that of the international spheroid. It is suggested that the geoid of South Siam is 100 feet higher than any geoid that fits in with those two arcs and that therefore South Siam shows some departure from isostatic equilibrium. This might lead to some earthquake in the near future.

In Chapter VIII on research notes, conversion maps are given showing the heights of the International Spheroid over the Everest Spheroid used by the Geodetic Survey, as well as over that of its spheroid II used since 1928. The short Chapter VI gives the value of longitude observed at Dehra Dun for the International project arranged by the Burma International de l' heure at Paris, working with four different instruments. Standardisation measurements are given in Chapter VII. Tide predictions from observations at 14 ports are given and the accuracy discussed.

B. DASANNACHARYA.

The Geology of Ceylon.*

THE island of Ceylon constitutes largely a continuation of the main geological formations of Southern India. Like the adjacent mainland it consists of large masses of ancient crystalline schists and narrow fringes of some of the later sediments deposited along the coastal strips.

Mr. J. S. Coates has recently published an account of the geology of the island, based on the results of his traverses over the greater part of the country, supplemented by numerous scattered observations which he had been able to make while engaged as Government Mineralogist. According to him nine-tenths of the island is occupied by the Archean crystalline schists with only a few narrow belts of sediments along the coast. The sequence of rock formations as given by the author is as noted below :—

Post Tertiary,
Miocene,
Jurassic,
Archean.

The *Jurassic* rocks are described as forming an insignificant series occupying a small area of less than a square mile in extent. They are found exposed near Tabbawa, at a distance of about 80 miles N.N.E. of Colombo, and form a series comprising of conglomerate, grits and sandstones, shales and nodular limestones attaining an estimated thickness of about 2,000 feet. The sandstones and shales are unfossiliferous, but impressions of a number of plant relics have been found in a clay bed. Amongst them, many of the identified species seem to be of lower Oolite and Upper Liassic horizons and correspond to the plant fossils recorded from the Madras Coast.

The *Miocene* rocks form the entire peninsula of Jaffna and they are also seen as narrow fringes in the north-west coast, extending to a width of about 10 to 12 miles inland. This formation consists mainly of fossiliferous limestone succeeded by a series of sandy argillaceous beds and mottled sandstones. The fossils from the Jaffna limestone include several identifiable species of molluscs and foraminifers. The palæontological evidence leads to the conclusion that this series of rocks of the north-west Ceylon are identical with similar rocks at Quilon in Travancore, and are of an older age than those of Karikal on the Coromandel Coast of India.

Pleistocene and Recent.—These post-tertiary formations consist of various types of coastal deposits, including sandstones, coral

* "The Geology of Ceylon," J. S. Coates. *Ceylon Journal of Science*, 1935, **19**, Sec. B, Part 2.

deposits and blown sand, a detailed account of which is given by the author.

Archean.—The Archean formations of Ceylon like those of the Peninsular India show a great variety of groups which are described under the following names:—

(*a*) *Bintenne gneiss.*—This name is given to a series of complex banded granitic gneisses covering an extent of about 5,000 square miles of the island in its south-eastern part. The biotite gneisses of this complex are noted to show very variable strikes, but they seem to dip consistently, especially in the eastern Bintenne area, everywhere conformably under the "Khondalite" rocks, forming possibly the floor on which the great masses of the latter group were laid down. The gneisses of this group form a composite series without any perceptible clear lines of junctions to enable one to separately classify and map the individual components. The Bintenne gneiss recalls certain features characteristic of similar gneisses of other Archean terrains, but it differs from the Bengal gneiss of India in having no intercalated beds of limestone or dolomite and also in containing very few accessory minerals.

(*b*) *Khondalite series.*—An extensive series of schistose and gneissic rocks comprising quartzite or granular quartz rock as its principal member, fissile quartz schists, finely banded quartz-felspar gneisses with or without biotite and garnet, impure crystalline limestones and a variety of garnet sillimanite schist, form among themselves a distinct group separable from the other gneisses of the island. They are confined almost to the central part of the island, covering an area of about 5,000 square miles.

They have a general resemblance in appearance and character to the great masses of the garnet-sillimanite-graphite schists or the "Khondalites" of the Kalahandi State in the north-east part of the Peninsular India. In Ceylon, varieties corresponding to the typical "Khondalites" of Dr. Walker, are rather rare, and many of the types differ from them generally in containing felspar and in not having graphite. The associated crystalline limestones or marbles, especially the darker varieties, contain abundant silicates like olivine, dark pyroxene, tremolite and pale phlogopite. Clinohumite is also found at certain places as a conspicuous constituent of these limestones. Pyrite, graphite, magnetite and spinel are some of the non-silicate minerals usually present.

The series with its intercalated bands of Charnockite is estimated to have a total thickness of some 30,000 to 40,000 feet. The rocks of this group, like the Khondalites of Peninsular India, are believed to have originated from the metamorphism of a series of sediments consisting of limestones, shales, sandstones and arkoses.

(*c*) *Kadugannawa gneisses.*—Bounding the western edge of the "Khondalite Series" in the central part of the island, is another series of rocks which outcrop as a thick lens of about 30 miles in length north and south and 8 miles across the thickest part, gradually tapering away at both ends. The types forming this complex are dense, black, glittering hornblendic rocks with more or less biotite and felspars, and comprise of banded, massive and schistose varieties. Some of the narrow bands are stated to contain mainly of pyroxene, while calcite seems to be always present. Attention is drawn to the close resemblance of these Kadugannawa gneisses to the calc gneisses of Fermor. The descriptions of these types as given, seem to fit in also with the types described as secondary pyroxene rocks or Tarurites from the Mysore State. The gneisses are regarded as metamorphosed calcareous sediments of probably the same age as the Khondalite Series.

(*d*) *Charnockites.*—The series of granulitic hypersthene rocks, comparable to the well-known "Charnockites" of Southern India are found widely distributed in Ceylon. They reach their greatest development in the south-west quarter of the island where they seem to be continuous over an area of about 4,000 sq. miles. They are also found as numerous thick sills between the schists of the Khondalite Series. Isolated exposures are found in other gneissic areas as well. Acid, intermediate, basic and ultrabasic types all seem to be represented.

The Charnockites of Ceylon are stated to differ from the Indian Charnockites in certain respects, *viz.*, in the almost complete absence of microcline, the widespread distribution of calcite, the prevalence of micaceous types and in the intercalation of numerous bands of garnetiferous leptynites.

Wanni gneisses.—A distinct group of reddish, pink or buff coloured gneisses and granulites of intrusive appearance is found in the northern half of the island. The

different types of this series are all characterised by (1) the paucity of ferro-magnesian minerals, (2) the abundance of magnetite, and (3) the comparative abundance of monazite.

These seem to correspond petrologically to some of the newer granites or gneisses of Peninsular India which have been found intruding the Charnockites.

Pegmatites and basic dykes are also found and among the latter, dolerites, peridotites and pyroxene scapolite dykes have been noted.

Among the economic minerals found and worked in the island, graphite, various gem stones, mica, thorianite, monazite and zircon sands are the most important.

B. R. R.

Diet and Climate.*

DR. CHICK'S "Cantor Lectures" on "Diet and Climate" cover a wider field than their title indicates. While she deals at length with the specific question of ultra-violet light and sunshine in relation to vitamin D, calcium metabolism, rickets, osteomalacia, etc., she has included also sections on diet as influenced by locality, race, and custom. In the first lecture she points out that one of the first important clues as to the cause of rickets was found in the study of its seasonal incidence and geographical distribution. As long ago as 1890, Theodore Palm put forward the theory that rickets is a disease of sunless places. His theory, broadly speaking, was correct, but it was not until over 30 years later that the reason *why* rickets tends to be a disease of sunless places was discovered. The explanation, which is at once remarkable, unexpected, and completely satisfying, was provided during the years 1918–30 as a result of the labours of many investigators working independently at different aspects of the problem in their respective countries. No single worker can claim credit as the discoverer of the cause of rickets.

Dr. Chick comments on the existence of rickets, and especially osteomalacia, in Northern India and China. In these regions there is plenty of sunlight capable of transforming the eyesterol normally found in the skin into vitamin D, but there exist "social customs which hinder access to fresh air and sunshine for women and children". At the same time there tends to be a deficiency of mineral salts in the diet. "Vitamin D can only control and correct the metabolism of lime salts and phosphates if these are present in adequate quantities in the diet; sunshine can only provide vitamin D if the inhabitants take advantage of the supply thus provided."

Wilson has shown that rickets and osteomalacia occur in Kashmir even in villagers fully exposed to sunlight. Here, it seems, the chief factor in the causation of these diseases is mineral deficiency rather than lack of vitamin D. The administration of tri-calcium phosphate has proved more effective in treatment than cod liver oil. As a result of the lack of calcium salts and phosphates in the diet, vitamin D, derived from sunshine, is unable to fulfil its proper function.

The lecturer emphasises the association between a high intake of milk and its products and good physique. As McCollum has remarked, "Wherever dairy animals are abundant in proportion to the population and their products form a staple article of diet, fine physical development is seen without exception." In India, McCay was the first to suggest a relationship between the physical characteristics of the various peoples and their staple diet. His investigations have been confirmed and extended by McCarrison, and precisely parallel observations have been made by workers in other parts of the world—notably by Orr and Gilks in East Africa. In England it has been amply demonstrated that an improvement in national physique could be brought about by an increased consumption of "protective" foods, notably milk.

Dr. Chick concludes with some wise remarks about the need for common-sense in applying in practice the scientific principles of nutrition:

> "A great deal of exact knowledge is now available and ready to be applied, but dietetics is not an exact science, and the application of the science of nutrition to the art of dietetics needs to be made with common sense and with intelligent adaptation to the particular circumstances. For example, it is vital that the Madrassi peasant or the Malay coolie should be weaned from rice

* The Cantor Lectures. "Diet and Climate" by Harriette Chick, C.B.E., D.Sc., *Journal of the Royal Society of Arts*, Sept. 13 and 20, 1935.

that is highly milled and polished and persuaded to take it with the bran and germ adhering to the grain. But it is not only silly, but also misleading, to tell the poor English working woman that she must pay more to secure 'unpolished rice' for her occasional rice pudding. In any case, the milk in the pudding and the egg, if present, will correct the deficiency of the highly-milled rice, even if the effect of other constituents of the diet is disregarded.

The use of pasteurised or boiled milk is another example. Milk so treated has a slightly impaired nutritional value, it loses most of its antiscorbutic value, which is never great, and some portion of its content of lime salts is converted to a less digestible form. In this country, however, the heating of milk before consumption is a necessity, since the danger of milk-borne disease is so great. Tuberculosis alone is widespread among our dairy cattle and is a menace to children taking large amounts of raw milk. Yet there are people who insist on the need for raw milk on dietetic grounds, although the defects in heated milk can be simply repaired by giving a little extra fruit juice or vegetable food.

These examples will suffice to show the need for common sense, and the dangers of faddism, in applying the results of scientific investigation to the practical problems of diet.

There remains the economic difficulty of providing a perfect diet upon inadequate means. The provision of cheap milk for school children by the local authorities is an important step in the direction, and other ways of encouraging the consumption of dairy products should be welcomed. In any case, the spreading of knowledge and the popularising of the less expensive 'protective foods' should do much to secure improved nutrition for our own population."

W. R. A.

Andrew Carnegie.

THE Centenary of the late Andrew Carnegie will be celebrated on November 25, 26 and 27 in New York, Pittsburg, Washington and other cities, according to an announcement made by Dr. F. P. Keppel, President of the Carnegie Corporation of New York, the largest of the six Carnegie Foundations in the United States.

Andrew Carnegie was born on November 25, 1835, in a weaver's cottage in Dunfermline, Scotland, the ancient Caledonian capital from which his family emigrated to America in 1848. It was in Dunfermline that Carnegie built his first library and began in 1881 his series of library benefactions that continued until 1917, by which time he had built 1,946 free public libraries in the United States and 865 in other parts of the English-speaking world.

The six Carnegie trusts in the United States are: Carnegie Institute of Pittsburg (1896) which conducts an Institute of technology, a museum of fine arts, a music hall, a museum of natural history, a public library and a library school; Carnegie Institution of Washington (1902) devoted to scientific research; Carnegie Hero Fund Commission (1904) to recognise heroic acts performed in the peaceful walks of life; The Carnegie Foundation for the Advancement of Teaching (1905) to provide retiring pensions for teachers and to advance higher education; The Carnegie Endowment for International Peace (1910) to serve the purpose indicated by its name; and Carnegie Corporation of New York (1911), for the advancement and diffusion of knowledge and understanding among the people of the United States and the British Dominions and Colonies.

The four British Carnegie Trusts are: Carnegie United Kingdom Trust; Carnegie Dunfermline Trust; Carnegie Trust for the Universities of Scotland; and Carnegie Hero Fund Trust.

—*Science*, 1935, **82**, 365.

Medicine-Man of the Red Indians.*

A MASTERLY treatise on the *Shaman* or the medicine-man of the Red Indians of the New World, written by a well-known professor of the Medical faculty of the Western Reserve University, has recently been published, and this should prove invaluable not only as an authoritative source of reference, but also as a model for future investigations on the medicine-men of the primitive tribes of other parts of the world. The work is further of special value in that it gives a succinct and concise account of the past history of the Red Indians and their influence on the development of the vast continents which have been their home from almost prehistoric times. Their present position is also discussed, and the author remarks that "while four hundred years is not a long time in the history of a race, it is sufficiently long, in a casual study such as I have given him, to obtain a fair conception of his past and to anticipate his destination. His tragic past is closed as the tide of empire westward took its way, and with this ends our theme of the aboriginal in his native state." The future is in the lap of the gods, but reading between the lines there seems little doubt that just as his medicine-man has passed so will the Red Indian in most parts of America under the stress of the modern day conditions to which, in spite of the attempts of the various authorities for his education and civilization, he has not been able to adapt himself; in certain areas he is already "gradually merging with the invading races of the Caucasian and the Negro".

In an introductory chapter the author starts with an attempt at a reconstruction of the family tree of the "American Indian". The name Indian, as the author points out, was a misnomer as applied to the inhabitants of the Americas when Columbus discovered the New World, for they are in no sense allied to the Indian of the Old World. From a careful review of the available evidence he concludes that the American Indian is not the primitive inhabitant of the New World, but migrated to North America some eight to twenty thousand years back across the Behring Strait route from the East Cape, Siberia to Alaska and later "penetrated every portion of the New World from Alaska to Patagonia". All Red Indians, however, did not migrate at the same time nor were they all of a single stock only. After referring to the distribution of the three main divisions of mankind—the Caucasoid, the Mongoloid and the Negroid—the author describes in some detail the racial characteristics of the American Indian, and agrees with the view of most authorities that he belongs to the Mongoloid division of the human race.

Defining Culture as "everything that man does, creates, thinks about and imagines, and hands to the next generation by precept. In short, it is all human behaviour, which is developed and used daily and which is handed down to the next generation by teaching and example," the author asserts that the cultural elements or traits brought with him by the American Indian from the Old World consisted of the "dog, the firedrill, the harpoon, basketry, ideas concerning the causes and cures for disease, family groups and some ceremonial rites." From this meagre inheritance the American Indians developed the highly evolved culture of the Aztecs and the Mayas in Central America and of the Incas of Peru in South America, without any extraneous influences. The two continents of North and South America are divided, on the basis of the different tribes inhabiting the various regions, into fifteen areas of Indian Culture. A short survey of the cultural development in the different areas and their history so far as known is followed by an account of their relationships and racial origin, their religious beliefs, their medicine-men and their conception of disease. After discussing the various tribes and their medicine-men, the author holds forth the view that the most universal and popular theory of the cause of diseases amongst the Red Indians is that of "disease-object intrusion". This is the theory which holds that sickness is due to the presence in the body of some foreign object, such as a fish-bone, a stick, a stone, or a bit of hair. After that, the following causes for illness, given in the descending order of their importance, may be listed: "soul-loss, sorcery, spirit intrusion, and finally, breach of taboo." Every tribe had and has its medicine-men who, before being recognised as such, had to undergo various

---

* *The Medicine-Man of the American Indian and His Cultural Background.* By W. T. Corlett. (C. C. Thomas, Springfield, Illinois.) Pp. ix + 369, 23 plates, 1935. Price $5 or *Sh.*22/6.

kinds of training, most of which was useless but some had an intrinsic value. The supernatural, of course, played a very important part in the Indian's healing ceremonies, but the medicine-man's job was to inspire confidence and faith on the part of the patient, and as in all medical practice, he used commonsense as the basis of his treatment.

The author includes several references to the surgical skill of the primitive medicine-men or *Shamans* and he quotes from Moodie about the surgical knowledge of the pre-Columbian Peruvians as follows :—" Their surgical attempts are truly amazing and include amputations, excisions, trephining, bandaging, bone transplants (?), cauterization and other less evident procedures." A chapter deals with child-bearing and the various attendant customs and ceremonies as also the part played by the midwife amongst the different tribes. Following such authorities as Morgan and Renaud, the author is of the opinion that " food played an important part in the distribution and culture of the Indian tribes of both South and North America," and he attributes the high stage of evolution of the culture of some of the tribes to their cultivation and use of the Indian *corn*—the maize—just as the " culture of the Orient was founded on rice, and that of Europe on wheat and other cereals". The importance of food in connection with the activities of the medicine-men is considered and the Materia Medica of the different tribes is described in some detail. The fantastic dress of the medicine-man, his medicine-bag, medicine-pipe and the sweat-house are described, and he is considered as " the mediator between his people and the Great Spirit " in trying to cure diseases.

The work is well illustrated and the detailed bibliography and the carefully prepared index greatly add to the usefulness of the work. It is indeed one of the most up-to-date books on the subject, and both the author and publisher are to be congratulated on its production.

Science Notes.

Production of Gases during Decomposition of Cane Molasses in the Swamp Soil.—G. Narasimhamurthy, M.Sc., Department of Biochemistry, Indian Institute of Science, Bangalore, writes :—Attention has already been drawn [Bhaskaran *et al.*, *Proc. Ind. Acad. Sci.*, 1934, 1 (B), 155] to the fact that a number of gases are formed during decomposition of cane molasses in the swamp soil. In view of the importance of the gases in relation to plant life, a few quantitative studies were carried out, examining the gases produced during two successive seasons, one hot and the other cold. The gases were collected over water and analysed according to the procedure outlined by Kane, Krishnaswami and Watson [*J. Ind. Inst. Sci.*, 1934, 17 (A) 33]. The results have been presented in Tables I, II (*a*) and II (*b*) :—

TABLE I.

Rate of Evolution of Gases.

Season : November—December 1934.

Time in Days	1	2	3	4	5	6	7	8	9	10	11	12
Vol. of gas collected in c.c.	Nil	Nil	Nil	98·4	201·1	121·2	69·1	44·8	40·8	27·7	Nil	Nil (No further evolution)

TABLE II (*a*).

Distribution of Gases.

Season : November—December 1934.

Time in Weeks	Percentage of the total volume						
	Carbon dioxide	Oxygen	Unsat. Gases	Carbon monoxide	Hydrogen	Methane	Nitrogen
	2·0	4·4	Nil	Nil	51·2	4·7	37·7
	[illegible]	Nil	Nil	Nil	1·0	12·7	75·3

TABLE II (*b*).
Distribution of Gases.
Season: April—May 1934.

Period in Days	Percentage of the total volume						
	Carbon dioxide	Oxygen	Unsat. Gases	Carbon monoxide	Hydrogen	Methane	Nitrogen
1— 3	13·0	3·9	Nil	Nil	7·5	2·3	73·3
4— 7	11·7	4·5	Nil	Nil	0·6	3·3	79·9
8—10	12·3	7·7	Nil	Nil	0·8	3·3	75·9
11—14	13·8	2·4	Nil	Nil	1·4	5·3	77·1
15—21	4·2	3·2	Nil	Nil	0·5	2·5	89·6
22—28	8·1	3·2	Nil	Nil	Nil	2·9	85·8

There was greater production of gases during the warm months than during the cold ones. The evolution of gases continued over a number of days, even long after the sugars were completely used up. The proportion of the gases was largely determined by the amount of free air space above the fermenting medium: there was increased production of hydrogen and methane with the reduction of air space, while increased air supply led to greater production of CO_2. Under no condition, however, was either carbon monoxide or any of the unsaturated gases produced. The large quantities of nitrogen and small amounts of oxygen present in all the samples were traceable to the air originally present in the soil system.

The author's thanks are due to Dr. K. R. Krishnaswami for much valuable advice and Prof. V. Subrahmanyan for his kind interest in the work.

* * *

The Thermal Structure of the Upper Air over a Depression during the Indian South-West Monsoon. N. K. Sur (*Indian Meteorological Department, Scientific Notes*, Vol. VI, No. 65).—A depression developed in the Bay of Bengal in the first week of September 1932 and passed through Orissa, the Central Provinces and Central India. From sounding balloon ascents at Agra during the week, it is found that temperature at upper levels below the tropopause at first decreased on successive days as the depression increased in intensity and approached Agra. When the depression deepened further and became practically stationary in the neighbourhood of Agra, an exception is noticeable at the levels between 8–12 gkms., where no fall of temperature occurred. At this stage the level of the tropopause above the depression was lowered with an increase of temperature in the lower stratosphere and a decrease at levels immediately below the tropopause. Inheritance of purple pigmentation in Setaria Italica, *the Italian millet.*—G. N. Rangaswami Ayyangar and his assistants (*The Indian Journal of Agricultural Science*, Vol. V, Part II), summarise their conclusion in regard to the inheritance of this purple pigmentation:—"Plants of the Italian millet are either pigmented (Anthocyanic) or without purple pigment (non-pigmented). The former condition is dominant and arises by the basic presence of a factor P. There are various manifestations and intensities in this pigmentation. A factor I determines a manifestation in intensity. This is dominant to a manifestation in a weaker depth. The degree to which P is operative in addition to being greatly influenced by the presence of I, is conditioned by two other factors V and H, which determine the alacrity with which P manifests in the vegetative or earhead parts. The interaction of P, I, V and H factors produces the diversity of forms characterising varieties of this millet.

Data from over 420 families are presented in support of the above hypothesis. A number of artificial crosses furnish confirmatory evidence."—(*Author's Summary.*)

* * *

Pungency in Chillies.—The inheritance of pungency in chillies (*Capsicum Annam* L.) forms the subject of an interesting study by A. B. Deshpande (*Ind. Jour. Agr. Sci.*, **5**, 4). The results are as summarised below:—"(1) Pungency is definitely a heritable character. The degree of pungency, however, is found to vary considerably with environment such as soil, climate, manurial treatment. (2) The genetic results show that pungency is a simple monogenic character dominant to non-pungency and is determined by a single factor which we have termed C. (3) 'Calyx not enclosing fruit base' has been found to be dominant to 'calyx enclosing fruit base" on a 3 : 1 basis. (4) Both pungency and the nature of calyx, when studied together, have been found to segregate on di-hybrid basis, each quite independently of the other." (*Author's Summary.*)

Preparation of Beer by the Nagas.—No *Ao* drinks if he can get rice beer (yi C, azu M).[1] Even if a man goes fishing he will take drinks down to the river. At festivals large quantities are drunk, and most people are fairly merry, but no one has ever seen an *Ao* dead drunk or heard of an *Ao* drinking himself to death. On the other hand, many men keep themselves alive for months on rice beer. "Madhu", as rice beer is called in Naga-Assamese, is so sustaining that in the case of old men it often takes the place of solid food. It is made as follows: Yeast (piyazi C; pazai M) is first prepared. To make it, husked rice is soaked in

[1] These remarks do not apply to the Christians who are strictly forbidden by the American Baptist Mission to partake of alcohol in any form.

water in an earthenware pot. The water is drained off and the rice pounded up with likok leaves and spread out on a winnowing fan. This dough is then divided up into four, six or eight elliptical cakes and a similar number of square cakes. The elliptical cakes are called male cakes and the square, female cakes. A layer of rice husks is then spread on a bamboo tray, and over the husks sugar-cane leaves, "to make the yeast sweet". The damp cakes are put on the leaves and after some old yeast has been crumbled over them they are left to dry till the morning of the sixth day, when they are considered ready for use.

To prepare "Madhu" rice is boiled and spread on a mat and allowed to cool. Then pounded yeast and a small quantity of rice husks are mixed with it, the woman who is preparing it saying: "Enter the plantain tree, climb the sugarcane, and be sweet." Immediately after it is mixed it is put into a basket lined with leaves. On the evening of next day it is put into tall baskets lined with plantain leaves and the juice is allowed to drain off at the bottom. This juice is the drink known in Naga-Assamese as "rohi madhu" (mechemzu C; mechem M). It is of about the potency of claret, and is the favourite drink of well-to-do men. To the English palate it is too sticky, and often too sweet to be a "clean" drink, but is very stimulating and by no means to be despised half-way up a long hill. For a thirst quencher the *Ao* prepares "Saka madhu" (tesenzukyi C; azu techenlak M), a drink resembling very thin gruel, and less potent than the lightest beer. To prepare it fermented rice from which the "rohi madhu" has drained is put into a sieve (sanku C; changku M), and hot or cold water is poured on to it. The milky fluid which results is the ordinary household drink of an *Ao* family.

* * *

Archæological Trial Excavations at Patna—Discovery of Ancient Wooden Foundations.—On receipt of a report from the Chaukidar at Kumrahar (near Patna) that traces of some wooden structure have been exposed in a brick-field, the Archæological Superintendent of the Central Circle, Patna, proceeded to examine the nature and extent of the ancient remains by trial diggings. The result was the discovery of a long wooden platform, about 100 feet in length and 5′–6″ in width, and 7′ in height running north and south. The bottom of this structure is 22 feet below the level of the road nearby and seems to continue at either end. Wooden structures were unearthed previously at the Bulandibagh and Kumrahar excavations by the Archæological Department, and another has recently been brought to light by the Public Health Department in course of laying sewage pipes to the east side of Kankarbagh Road. The minor antiquities found at Gonsai Khanda consisting mainly of small pottery cups, potsherds and terracotta balls, etc. are similar to those discovered at Kumrahar and Bulandibagh and may be attributed to the Mauryan epoch. A small walling of Mauryan bricks was also found at right angles to the wooden structure near the top. The particular purpose for which all these wooden structures at the ancient site of Pataliputra were constructed is not determined. The Bulandibagh pieces might well have formed part of the old wooden palisade of Pataliputra but the Gosai Khanda construction is more likely to be a coffer dam erected in connection with training and revetment of a river bank or the construction of a wharf. The favourable situation of ancient Pataliputra at the confluence of the Son and the Ganges, made it a great centre of inland water-borne traffic, and there must have been a river port of considerable importance at Pataliputra, and wharfs and docks must have been found necessary, where such coffer dams of which the remnants have been laid bare were sometimes constructed.

* * *

Some Early Indian Paintings Discovered by Prof. Jouveau-Dubreuil in Tinnevelly District.—At a recent meeting of the Archæological Society of South India, Messrs. T. N. Ramachandran and C. Sivaramamurti, exhibited copies of some early paintings discovered on the ceiling of the mandapa and on the pilasters of a cave temple in Tinnevelly District. The temple bears an inscription of the 12th–13th century A.D. relating to the Pandyan King Srivallabha. The paintings appear to be of Pandyan art, and no paintings representing this were previously known. The paintings are relatively rich in *rekha* or line and lacking in *bhushana* or ornament.

Mr. Paramasivan gave an account of the technique of the process of painting used. The pigment consists of a mixture of yellow particles (yellow ochre) and much-faded blue particles (indigo). The binding medium appears to have been starch paste but this is very far from certain.

* * *

The Patwar Meteorite.—At the ordinary monthly meeting of the Asiatic Society of Bengal held on 4th November 1935, Dr. A. L. Coulson presented an interesting account of the meteoric shower which occurred at about 14.20 hours on the 29th July 1935, near the village of Patwar (23° 9′: 91° 11′), Bhatupara, Gotrasal, Fatehpur and Majhipara near Nangalkot, some 20 miles due south of Comilla, the chief town of Tippera district. Two months ago Dr. Coulson read a paper on the Perpeti meteoric showers (see *Curr. Sci.*, 1935, **4**, 120). "Patwar is only some 17 miles south-east of Perpeti, also in the Tippera district. The two falls, however, are distinct but it would be interesting to learn of any other occurrence of two separate meteoric showers within 17 miles of each other after a lapse of two and a half months.

"So far three specimens, totalling 35,013.5 grams, which fell at the three first-named villages have been recovered, the largest (23,111.6 grams) falling at Patwar which gives its name to the fall. However, two small additional stones from the villages of Fatehpur and Majhipara have been recovered and sent to the District Magistrate, Comilla.

"The fall was accompanied by the usual phenomena of light and sound. A dazzling light following a "loud rumbling noise" is supposed to have been the first indication to the villagers of the fall of the meteorite. The sound is stated to have been so loud and continued, that those in the police thana at Chauddagram, some 7 miles to the north-east of Fatehpur, the nearest locality to the thana from where stones were recovered, distinctly heard it. Four reports "like thunder" were heard in quick succession. One observer adds that a peculiar sound like "that of an

aeroplane" followed the reports; this may have reference to the passage through the atmosphere of the disrupted members of the parent meteorite.

"The largest specimen penetrated to the ground to a depth of 34 inches.

"The parent meteorite appears to have been moving in a west-south-westerly direction. The smallest pieces fell first, followed in succession by the larger. The total rectangular area covered by the shower is roughly about 4½ square miles, the length being some three miles in the direction E.S.E.-W.S.W.

"The meteorite has great interest on account of its rather rare composition. It belongs to the group of mesosiderites, being a siderolite intermediate in composition between a stone and an iron. It contains large crystals of olivine and masses of nickel-iron of fair size. It is composed chiefly of nickel-iron with olivine, enstatite and bytownite, with smaller amounts of schreibersite, troilite, oldhamite, lawrencite and hydrocarbons. Its specific gravity is 4.21."

* * *

The Doon School.—India's First Public School, the Doon School, run entirely on lines on which Schools in England are conducted, was opened by H. E. the Viceroy on the 27th October. There are in India institutions on a residential basis, but they invite particular class of students, *e.g.*, chiefs' sons, or are intended to prepare for a particular career in later life, *e.g.*, army. The School, which is the first of its kind in the country, and at present considered to be of the nature of an education experiment, owes its inception to the late Mr. S. R. Das, who was the originator and founder of this great venture. It is run entirely on British lines and the Principal, Mr. A. E. Foot, is one who has considerable experience of Public Schools in England. The main purpose of the institution will be to provide education to young men and women, which will enable them to become useful citizens of the country. This education will help in the formation of character, "which will develop our citizens with a high sense of honour, of responsibility and of discipline, qualities which are absolutely essential to all services in public life." There are boys in the School from all Provinces and many Indian States. All religions are respected. The School is open to Indians of all castes and creeds and will be run as an individual unit with a purpose, a function and aim all its own.

The School, at present, has a strength of 70, which will be raised to 180 by next February and the School will ultimately provide education for 400 boys. The Doon School is located in an estate known as 'Chand Bagh' in Dehra Dun. Negotiations are in hand to acquire an adjacent estate known as Skinnes' estate, which will provide for further extension.

* * *

Asiatic Society of Bengal.—Dr. Sunder Lal Hora of the Zoological Survey of India gave a paper on "Recent Indian Cases of Live Fishes Impacted in the Food and Air Passages of Man" at the Medical Section of the Asiatic Society of Bengal on the 18th instant. Lt.-Col. B. G. Mallya dealt with the surgical aspect of such cases. It is understood that the paper, which is bound to be of great medical interest, will be published shortly.

It was understood that Dr. Hora would have been able to exhibit a specimen of a small fish impacted in the pharynx of man, preserved in the Pathology Museum of the Medical College, Calcutta, but unfortunately, the specimen had crumbled into pieces and was not available for exhibition.

* * *

The Industries Conference.—The Seventh Industries Conference was held at New Delhi, on the 28th and 29th October, and was opened by Sir Frank Noyce, Member for Industries and Labour. The Conference has concentrated its attention on the development of the Handloom Industry and at the last Conference held in July 1934, a sum of Rs. 5,70,000 was allotted to Provincial Governments for expenditure on approved schemes during the 17 months from November 1934 to March 1936. The schemes are of varied character, including the training of weavers in improved methods of production, establishment of sales depots and weavers' co-operative societies for marketing handloom products and introduction of new patterns, new designs and improved appliances. The Conference reviewed the progress achieved in the working of the various schemes. The schemes were initiated only recently, and much could not have been achieved. The prospects of success are however indicated; and it is expected that for the next year more grants would be made available. The Conference has agreed to hold an exhibition of handloom machinery and fabrics in February 1936, (9th-24th) at Patna and will organise a competition for handloom weavers. The Conference also discussed questions relating to the abolishing of restriction in respect to fees charged in technical institutions from students belonging to the Province and those coming from other provinces. Another important subject discussed was the regulation of labour (particularly child labour) in unregulated factories and workshops.

* * *

The Imperial Sericultural Committee, which was established in accordance with the recommendations of the Tariff Board, held its second meeting on the 31st of October. It may be recalled that at the first meeting held on February 25th grants amounting to Rs. 93,000 were allotted to various provinces for working out schemes, connected mainly with the increase of the production of disease-free seed and the investigation of silk-worm diseases. The Committee reviewed the work and decided to recommend further allotments from the Sericulture Fund for 1936–37. The proposals for the improvement and development of the Sarrar Silk Industry in Bihar and Orissa and for the expansion of the sericultural farm in Shillong, were considered and approved.

* * *

The Institute of Engineers, India, has been granted the Royal Charter. This is the first instance of the Charter being granted to a professional body, which has its origin and function solely in India. The Institute was formally constituted as a corporate body with Sir Thomas Ward as the first President on September 13, 1920, and was inaugurated by Lord Chelmsford on February 23, 1921.

* * *

Education and Vocational Training.—In the course of his inaugural sessional address at the

opening of the ninety-fourth Session of the College of the Pharmaceutical Society, on October 2, Sir Frederick Gowland Hopkins discussed, among other topics, the one on "how far vocational training is compatible with true education in which a subject is studied for its own sake as an intellectual exercise." It has often been said that science can only be taught properly when it is taught as pure science without reference to its applications. This claim is justified to the extent that vocational needs must not make the teaching of science so one-sided that the student risks missing the intellectual stimulus which the great generalisations of science provide.

"Teachers of applied scientific subjects will be grateful to the president of the Royal Society for his declarations that the skilful teacher of students whose ultimate aim is to apply science in practice, can illustrate general principles adequately while selecting facts and aspects which have a permanent vocational value. Indeed, for the encouragement of the average student, it is important that the reality of this permanent value should be part of his faith. Without it he can never be an enthusiast for his calling. The preference for vocational training may well be based on the Anglo-Saxon preference for action rather than thought and for practice rather than theory, but it is an attitude of mind having in it the seeds of certain dangers. Indeed, a distrust of theory has sometimes kept Great Britain from being in the van of intellectual and not less of commercial progress."—(*Nature*, Oct. 12, p. 614.)

* * *

Counting by Eights.—In an interesting article published in the *School Science and Mathematics* (April 1934), E. M. Tingley, 221, North Cuyler Avenue, Oak Park, Illinois, U.S.A., has made a vigorous plea for calculating by *eights*, not by *tens*. Humanity has been adopting the metric system for over eight centuries. Mr. Tingley considers that the base eight is more natural. We have two eyes and two hands; we prefer to double or halve things. "Halves of things are much easier to comprehend than thirds or fifths, because halves are simpler and fewer. Therefore we should also use measures and an arithmetic base containing only even factors to treat the preferred even divisions. Eight gives the best even scale or base for this arithmetic." The decimal counting and calculating scale contains the odd fives, and it is said, calculation based on fifths and thirds is troublesome.

The question is a very serious one, and to discard a system which has been in vogue ever since the present method of writing numbers was devised (750 A.D.) in preference to a new system, it is necessary to have convincing psychological proof. The psychologists should measure our preferences towards the two systems and declare which of them is more natural and simpler to comprehend.

* * *

Synthetic Rubber.—A proclamation has recently been issued by Herr Hitler to the effect, that s the problem of producing synthetic rubber be regarded as definitely solved, the he first factory in Germany for this be begun." Thus to the synthetic productions of more has been added. Rubber is one of the cheapest and most plentiful of raw materials, and attempts are not wanting for cheapening it further by systematic work on the plantations and in the factory. The German chemists at the Interssen Gemeinschaft have now succeeded in supplanting rubber by an artificial product and further developments are awaited.

* * *

Real Silk Industry.—So much is being written and spoken about the artificial silk industry, that an impression is gaining ground that the real silk industry is doomed to extinction. An article appearing in a recent number of *Chemical Age* (Oct. 12th, 1935) by A. T. Hall, on real silk, however, serves to give a scientific picture of the real position.

For many purposes, pure silk cannot be replaced by rayon and indeed in some lines, "pure silk is ousting rayon." Thus in the hose industry, pure silk is becoming increasingly popular. Rayon becomes much dearer in the form of fine yarns, while the price of fine pure silk yarns is not much different from that of coarser yarns.

In the actual processing, the degumming of silk has attracted considerable attention at the hands of the research chemist. Sericin is the gum which cements together the raw silk threads which when taken from the cocoon are harsh, lustreless and coloured, while possessing strength. Sericin can be removed by aqueous solutions of alkalies and in recent years, sodium silicate is being used extensively together with soluble sulphonated oils. Degumming gives soft, lustrous silk, which is almost colourless. There are actually three sericins, distinguished as sericin A, sericin B and sericin C. Sericin B is a very valuable compound as it possesses excellent dispersive and penetrating properties which become effective when degumming liquor is used to assist in the dyeing of silk yarns.

* * *

Coal Hydrogenation Petrol Plant.—The opening of the petrol plant by Mr. Ramsay MacDonald on the 15th October at the Billingham Works of the Imperial Chemical Industries, Ltd, has brought to a practical commencement an enterprise which marks a revolution in fuel technology. The plant is the first in the world for the hydrogenation of bituminous coal. The process, due to Prof. F. K. R. Bergius, consists essentially in hydrogenating raw coal cleansed to less than 2½ per cent. of ash and ground up to a paste with oil to give a 50 per cent. coal-in-oil paste. This is injected into converters against the working pressure of 250 atm. and mixed with hydrogen. The mixture is heated up to 450° C. and the hydrogenation takes place at a temperature of 450° C. and 250 atm. pressure. A small heavy oil fraction containing the unconverted coal (about 5 per cent. by weight) and ash separates and is treated for oil recovery, the coke residue being used as a fuel. The major part of the coal is transformed into lighter oils which are separated and distilled into heavy oil, middle oil and petrol. Heavy oil is further hydrogenated to give middle oil and petrol. The middle oil is hydrogenated again in vapour phase converters, in which the vaporized light oil and hydrogen are passed over a solid catalyst. The crude vapour phase product is distilled, the residual middle oil being separated from petrol and treated again. The whole

of the coal is thus transformed into small consumable solid residue, gas and petrol.

The hydrogenation of coal is a self-contained process as the only raw materials used are coal and water, and if desired petrol can be the sole end product. Conditions can, however, be arranged to give fuel oil, diesel oil, petrol and liquefiable hydrocarbon gases such as propane and butane. The company started work on hydrogenation in 1927, and since that date has spent over a million pounds over research on that one subject, and in 1930–31, a small plant was installed for treating 15 tons of coal per day. The present output is 400 tons of petrol per day representing a total annual output of 45,000,000 gallons, forming only 4 per cent. of the country's consumption of petrol. The production, for a long time to come, may be in the nature of a supplement rather than a principal source, but still from this and other plants that might be erected in due course, there is reasonable chance of this supplement increasing in quantity. 4 tons of coal are required to produce about a ton of petrol.

* * *

Arctic Exploration.—An extra strong wooden ship whose ultimate duty will be to become frozen in Arctic ice and drop into ice fields with high latitudes will be completed early in 1937. Professor Wiese, the Soviet explorer, has announced, that in general, the design of the ship will form that of *Fram* used for similar duty by the Nansen expedition to the Arctic in 1893–96. The chief object of the expedition which will use the new ship will be a thorough study of the deep parts of the Arctic basin which are covered the year round with ice crust so thick that the strongest ice breakers cannot pierce it.—(*Science*, 1935, **82**, No. 2127, Suppl., pp. 14.)

* * *

British Industries Fair, 1936.—The next British Industries Fair will be held in London from February 17th to February 28th, 1936. Information regarding the Fair can be obtained from the High Commissioner for India, India House, Aldwych, London, W.C. 2.

* * *

Chemical Research in China.—"The rapid growth in the amount of chemical research, both pure and applied, in China during the last decade, is phenomenal. Research institutes are springing up everywhere, and a genuine effort is being made to give experience in research as an integral part of the training of every University Science graduate. Attention is being continually devoted towards the scientific study of the old chemical industries which flourished in ancient China. The British Boxer Indemnity Fund, for example, is supporting research at Yenching University aiming to improve the pottery industry of Peng-Cheng, Shansi. At Nankai University and the Golden Sea Research Institute, projects of a similar nature are being undertaken. Specialists on rural economics are stressing for China, improvement and further development in the village industries.—(*Ind. Eng. Chem., News Edition*, 1935, **13**, 358.)

* * *

Consequent to the retirement of Diwan Bahadur Sir T. Vijayaraghavacharya, the following officiating arrangements have been made from 26th October 1935:—

Mr. B. C. Burt, Vice-Chairman of the Imperial Council of Agricultural Research.

Dr. F. J. F. Shaw, Agricultural Expert to the Imperial Council of Agricultural Research.

Rao Bahadur B. Viswa Nath, Director, Imperial Agricultural Institute, Pusa, in addition to his duties as Imperial Agricultural Chemist.

* * *

Dr. S. K. Mitra, Professor of Physics, University College of Science, Calcutta, has proceeded to Europe on a Travelling Fellowship under the Calcutta University, for the purpose of studying the recent developments in wireless and television.

* * *

Dr. S. N. Chakravarthy, and Messrs. K. S. Venkataramani and Ramaswamy Sivan have been declared elected by the Senate to the Syndicate of the Annamalai University.

* * *

It is understood that the Senate of McGill University of Canada has sent felicitations to its oldest graduate—Dr. Griffith Evans of Bangor (Wales), who recently celebrated his 100th birthday. Dr. Evans took his M.D. Degree at McGill in 1864.

* * *

Noble Lauriateship for 1935.—Chemistry: Professor Joliot and Madame Curie-Joliot. Physics: Professor James Chadwick. Physiology and Medicine: Professor Hans Spemann.

* * *

Cornell University.—A gift has recently been made to the University by Dr. L. H. Bailey, Professor Emeritus of Agriculture and Mrs. Bailey of one of the most extensive herbariums in this country. This collection comprises over 125,000 mounted herbarium sheets, especially rich in cultivated material, and there are also included in the gift 4,000 technical books related to horticulture and botany, thousands of photographs, working equipment, etc., the buildings which house the collection, and about 0.25 acre of land. In accepting the gift the University has authorized the establishment of an administrative unit in the College of Agriculture to be known as the Liberty Hyde Bailey Hortorium. This will be under the direct supervision of a staff member and with a full-time curator and an advisory board consisting of the supervisor, the curator, representatives of the major fields of plant science, and two members at large. One or more graduate fellowships to be known as the Liberty Hyde Bailey Botanical Fellowships will also be established.—(*Experiment Station Record*, Vol. 73, No. 2.)

* * *

Bibliography of Soil Science, Fertilizers and General Agronomy, 1931–34.—The Imperial Bureau of Soil Science has recently published this bibliography consisting of over 6,000 references to papers, bulletins and reports published throughout the world in the years 1931–34, and dealing with pure and applied soil science. The volume contains (1) an index to the decimal classification, (2) an alphabetical cross index to every subject on which the papers listed have been written, (3) an author index containing over 4,000 names, and (4) a list of abbreviations used, and the full titles and places of issue (where known) of 800 journals, etc., from which the references in the bibliography have been taken. The bibliography containing 504 pages, is bound

in cloth, and is priced 25*s*. net, and can be obtained post free, from the Imperial Bureau of Soil Science, Harpenden, Herts, England.

* * *

The Indian Physico-Mathematical Journal, September 1935.—*The number of representations of a large number as a Sum of* n *non-negative* nth *powers :* By S. Chowla. The following theorem is proved: For a fixed value of n, $r_{n,n}(N) \neq O(1)$ *i.e.*, for an arbitrary value of A, we can find infinitely many values of N such that $r_{n,n}(N) > A$. The symbol $r_{s,n}(N)$ denotes the number of representations of N as a sum of *s nth* powers $\geqslant 0$.

* * *

The Mathematics Student, June 1935.—(1) *On G-Functions in General :*—By Hans Raj Gupta. In previous papers, Mr. Gupta has studied some properties of $G(n, r)$ where

$$(x+1)\ (x+2)\dots(x+n) = \sum_{0}^{n} G\ (n, r)\ x^{n-r}$$

In the present paper, the author attempts a general definition for the function $G(x, \rho)$ for all values of x, ρ being a positive integer $\geqslant 1$ and mentions that his results have been useful in a paper of his on "Ward's Numbers" under publication.

(2) *Focal lines of a Cone touching four given concurrent planes :* By A. A. Krishnaswami Ayyangar.

If the planes are parallel to the faces of a tetrahedron, the author proves that the focal lines are parallel to the axes of circular cylinders circumscribing the tetrahedron.

The theorem is the outcome of Mr. V. Ramaswamy Aiyar's paper on "Circular cylinders circumscribing a tetrahedron" in *Math. Student*, Vol. II, No. 3.

A few corollaries are added.

C. N. S.

* * *

Messrs. Chapman and Hall.—We have been informed that Messrs. Chapman and Hall, the well-known publishers of General Scientific and Technical books, have been appointed sole agents for the British Empire, for the CHEMICAL CATALOG Co.. of New York, from 1st November 1934. This news will be welcomed by all, particularly chemists, in all parts of India, as they are thereby enabled to obtain the Volumes direct from Messrs. Chapman & Hall, Ltd., 11, Henrietta Street, Covent Garden, London, W.C. 2.

A full list of the books of the Chemical Catalogue Company have been prepared and can be obtained from Messrs. Chapman & Hall, Ltd., London.

* * *

Recent Publications.—Edward Arnold & Co., London :—

Forensic Chemistry, and Scientific Criminal Investigation, by A. Lucas, O.B.E., F.I.C.

The Structure of the Alps, by Leon W. Collet, D.Sc.

The Oyster, and the Oyster Fishery, by J. H. Orton.

Announcements.

Krusadai Biological Station.—The following scale of fees will be levied from post-graduates and under-graduate student parties from Colleges and Universities for services rendered by the Krusadai Biological Station in connection with the collection and study of marine fauna and flora :—

1. Post-graduate workers such as M.A. and M.Sc. students, and Professors doing research.	Rupee one per day for the first three days and annas eight per day for the subsequent days of halt.
2. Under-graduates who come for collection of specimens.	Annas eight per day for the first three days and annas four per day for the subsequent days of halt.
3. The Professors who accompany the under-graduates that do not do research of their own.	Do.

* * *

Discussions at the Indore Meeting of the Indian Science Congress.—The following discussions, which will be held during the meeting of the Indian Science Congress at Indore in January next, are announced in advance in order to enable those who may wish to take part to have an opportunity of preparing their remarks. The following joint discussions have been arranged :—

Agriculture and *Medical Sections*, "The Making of Humus and its Application";

Chemistry and *Physics Sections*, "The Structure of Molecules";

Medical and *Physiology Sections*, "The Problem of Nutrition in India"; and

Botany and *Zoology Sections*, "The Teaching of Biology in Secondary Schools".

The following discussions, confined to single sections, have also been arranged :—

Chemistry Section, "The Scope of Preparation of Fine Chemicals in India", and "The Utilisation of Molasses";

Geology and *Geography Section*, "The Classification of the Archæan Rocks of India":

Botany Section, "The Myxophyceæ", "Saltation in Artificial Cultures of Fungi", "The Standardisation of the Vernacular Names of Indian Plants", "Chromosome Morphology and Polyploidy", and "The Importance of Anatomy and Taxonomy".

"Some Mathematicians I Have Met."*

[Prof. Born prefaced his remarks by saying that he was not a professional mathematician and was grateful for being asked to talk not a mathematical problem, but on a general subject. He proceeded to classify the many mathematicians he had met as falling under the three generations of teachers, colleagues or friends, and pupils.]

RECALLING his early days at Breslau where he attended courses of lectures on Philosophy, Chemistry, Physics, Astronomy, Economics and Law, he mentioned the profound impression created by his astronomical studies and by the old Observatory of his College, the instruments going back to the times of Wallenstein and his astrologers, the most modern being a meridian instrument of Bessel (about 1800). In Mathematics his teachers were Rosanes from whom was acquired the first clear idea of mathematical infinity and the technique of matrix calculus which stood in such good stead, later on, for the development of quantum mechanics; and London, the father of F. London who is now well known to physicists by his work in collaboration with Heitler on the theory of valency.

And then at Heidelberg with Kœnigsberger, the biographer of Jacobi and Helmholtz. Kœnigsberger was an Anti-Kant and an Empiricist who even maintained that the formula $(a+b)^2 = a^2+2ab+b^2$ could be derived only from experience! The methods of differential geometry were acquired here and it was mentioned how these good old methods came in handy quite recently for the new field theory, when Weierstrass' results on minimal surfaces were suggested to Pryce in connection with his work on the two dimensional electrostatic case.

It was next at Zurich that he met for the first time a brilliant modern mathematician Hurwitz, a friend of Minkowski and Hilbert. Hurwitz, so well known by the "Hurwitz-Courant" of the yellow series of volumes, was a most inspiring lecturer too.

And at last Göttingen! Of whom else at Göttingen should he talk first if not of Hilbert who is, by common consent, the doyen of present-day mathematicians? Prof. Born spoke at length about his distinguished teacher, of his stimulating lectures, his mathematical work, his influence on his students and his personality. He recalled a hiking excursion to an old ruined town Plesse with Minkowski, Hilbert and Caratheodory during which he mustered sufficient courage to approach Hilbert and ask him why he studied Mathematics. The answer, so characteristic of Hilbert, was that he had chosen this subject because he had a bad memory! Hilbert's lectures in the class-room left the greatest impression

* Summary of a lecture delivered by Prof. Dr. Max Born before the Central College Mathematical Society, Bangalore, October 1935.

on his hearers and had the quality of everlasting stimulation. He would set out to devise in the class-room new and better proofs of theorems, invent new theorems and if unsuccessful return the next day with beautiful results which have been the admiration of the mathematical world. His mathematical activity could be classified into six periods: (1) Numbers, (2) Invariants, (3) Axioms of Geometry, (4) Integral Equations, (5) General Relativity and (6) Mathematical Logic. Hilbert laid the greatest stress on rigour and logical foundations and on the meaning of pure thinking independent of content. He was perhaps not endowed with the gift of physical insight commensurate with his genius in mathematics and he never felt quite happy in his relations with physicists as evidenced by his quarrel with Pringsheim. Talking about his personality Prof. Born called it strange and likened it to a crystal with sharp edges. People did not understand him. His thinking never went the smooth path of everybody's opinion, but was absolutely independent and unconventional. He had a sharp tongue and was not always what one would call a nice fellow, but he was faithful and good to his friends. He took great interest in politics where, as in everything else, he went his own way and liked to shock people by his opinions, which were always well founded. Even when he changed from extreme pacifism in which he believed during the war into a conservative attitude during the socialistic revolution, he had good reasons for doing so.

Talking next about Klein, the contrast between Hilbert and Klein was pointed out. Klein disliked in his lectures rigorous methods and preferred to give the constructive ideas of mathematics. Having undergone a breakdown in health on account of overwork in trying to keep ahead of Poincaré, he assumed the rôle of an educationist and took great interest in presiding over mathematical societies and in reforming methods of mathematical teaching. A very amusing incident was narrated of how Klein went on discussing, at one of the meetings of the Mathematical Society a Dutch book on "Flacke Krommen" and talked at length about the theory of surfaces until at last it was pointed by one of the audience that "Flacke Krommen" did not mean "Krumme Flächen" but "Ebene Kurven"!

Then came Minkowski who was attached to Hilbert in the most intimate friendship. Minkowski delivered brilliant lectures on Geometry and other topics. His actual original contributions to relativity have perhaps not been so far appreciated properly. It was during the seminars on electrodynamics conducted by Hilbert and Minkowski that the latter was developing his four-dimensional world theory when Einstein's paper appeared and it can be safely said that Minkowski's work was done quite independently. Prof. Born mentioned that his own first paper in Breslau was on relativity, *viz.*, on hyperbolic motion which caught Minkowski's notice who asked the author of the paper to be a lecturer at Göttingen.

Last but not least among the giants of Göttingen was the brilliant Carl Runge, the applied mathematician and spectroscopist, who it was
of. Born into modern physics.
ure of the mathematical life
ose days was the Thursday
afternoon walk of Klein, Hilbert, Minkowski and Runge. A separation of this company was effected by the sudden death of Minkowski from appendicitis and on this occasion Hilbert delivered his famous memorial speech on Minkowski. In this connection it is interesting to know that in Hilbert's estimation Cantor, Minkowski and Hadamard, three Jews, were among the first order mathematicians.

Minkowski's successor in Göttingen was Landau, well known for his brilliant work on the analytical theory of numbers and many other subjects.

Passing on next to his friends and colleagues, Prof. Born mentioned in the former category the names of E. Schmidt (Berlin) known for his work on integral equations and potential theory Caratheodory of real variables and variations, Zermelo of Mengenlehre, Herglotz, Max Abraham and others. When talking of Kœbe, an incident that happened at Rome when the International Mathematics Congress met there, was narrated of how when looking at the celebrated paintings of Michael Angelo in the Sixtina Chapel, Kœbe burst out on the ephemeral nature of works of art of this type as contrasted with his uniformisation theorems which would stand for all time! This was how he acquired his nickname of "Kunstmäcen." The other lecturers at Göttingen were Hermann Weyl famous for his group theory, Hecke, Tœplitz, Courant and Emmy Nœther, who has died recently in America. At her funeral Weyl said in his commemoration speech, that she is considered as the greatest woman mathematician known in the history of science, greater even than the famous Sonja Kowalewski.

The associations with Planck and Einstein at Berlin in war time were next touched upon. It was unfortunate that Einstein should have got mixed up in politics with his strong tendencies towards pacifism, liberal doctrines and socialism. This led to the unfortunate conflict with Lenard and Stark. Einstein's scientific work could be divided into two periods—the physical and the later mathematical period of which the first seems to be far more fruitful.

Talking in general terms, Prof. Born said that as a rule the physicists he had met were more "normal" and therefore less interesting than the mathematicians. An exception, however, was the case of Ehrenfest who was a strange character. He was a true cosmopolitan, born in Vienna, educated partly in Germany, thoroughly acclimatised in Russia, and at last Professor at Leiden in Holland. He was a man of intense feeling with a great capacity for pure and clear thinking. His house was bare without any furniture and a wall of it served as visitor's book whereon could be found the names of all great men who visited him! Freedom from tradition was a passion with him. He got his meals from public kitchens and never sent his children to school for their education. His Russian wife and his eldest daughter both were called Tatjana, but for distinguishing between them his friends used to style them (Tatjana) and (Tatjana)'! He died under tragic circumstances having committed suicide by shooting himself with a revolver; this fatal step was the result of a deep depression which overcame him very often when he found difficulties to keep step with the progress of the younger generation of theoretical physicists.

A rapid survey was then made of the foreign mathematicians and theoretical physicists whom he had met. In referring to Niels and Harald Bohr, he spoke of the former's great gift of physical intuition and likened him to a magician who, though not much of a mathematician, could grasp the physical aspect of a problem immediately. Amongst the Dutch scientists the palm was given to Lorentz, a great leader of scientific activity and the President of the Solvay Congress. Lorentz's lectures at Göttingen were then recalled. Reference was also made to Kramers, Ornstein and Brouwer. Brief mention was made of Poincaré, Hadamard, de Broglie and Brillouin in France, of Levi-Civita and Fermi in Italy, of Frenkel, Alexandrow and Fock in Russia, and of Moore, Birkhoff, Veblen, Wiener, Alexander, van Vleck (senior and junior) in America. Amongst the English mathematicians and physicists he had met, Prof. Born talked about Hardy, Littlewood, Darwin, Fowler and Dirac. About the silent Dirac, Professor at Cambridge, mention was made of the 'unit' invented by his friends, *viz.*, 1 Dirac = 1 word per hour !

In the last category of his pupils, Prof. Born spoke about Pauli, Heisenberg, Jordan, Hund, Dirac, Fermi and v. Neumann whose book on quantum mechanics was considered to go deepest into the subject. B. S. M.

What are Cosmic Rays ?

It is well known that X-Rays and the radiations emanating from the radioactive substances ionise air so that it becomes a conductor for the flow of electricity. It was found at the end of the nineteenth century that air possesses a residual ionisation (after all the contributions to ionisation from radioactive sources were taken into consideration or suppressed). This result did not seem surprising at first as the residual ionisation was attributed to the defects of the instruments or to the presence of minute quantities of radioactive substances, too minute to be detected. It was subsequently found that the phenomenon of the residual ionisation disappeared in deep mines, had an altitude effect and possessed many other peculiarities. Hess, Kolhorster, Bergwitz and Gockel found that the phenomenon depended on the altitude. Balloons provided with automatic arrangements for recording ionisation were used in the earlier experiments. In a recent flight, Piccard flew to a height of 16 kilometers and recorded an ionisation as great as 200 ions per c.c. per second in the upper atmosphere. These facts support the view that the residual ionisation is genuine.

The radiations emanating from radioactive substances responsible for the ionisation of the air are α-rays consisting of α-particles whose penetrating power is small, β-rays consisting of very high velocity electrons of a moderate penetrating power and γ-rays which are electromagnetic in nature with a very high frequency. It is natural to think that the primary radiation responsible for the residual ionisation of the atmosphere is due to some extreme form of either β-rays or γ-rays. There is one school of thought, led by Professor A. H. Compton, who interpret the residual ionisation as due to very high velocity electrons like those of the extreme form of β-rays, pouring like a rain on the earth from the outer space. There is another school of thought led by Professor R. A. Millikan, who hold the opinion that the primary radiation responsible for the residual ionisation is electromagnetic in nature like the extreme form of high frequency γ-rays. Apart from the divergence of the opinions held by the physicists, the phenomenon of the residual ionisation seems to be certainly connected with some processes occurring in the outer space or with causes not at all understood in Modern Physics. The radiations responsible for the residual ionisation of the atmosphere have been called the cosmic rays. It is important to realise that for observing the phenomenon, it is necessary to detect a very feeble ionisation of the air amounting in the average to a few ions, say 1 to 2 per c.c. per sec. at the sea level.

In 1929, Regener reported that the phenomenon of residual ionisation could be observed in Lake Constance even at depths of 750 feet below the surface and found that the relation between the intensity of ionisation and depth could be represented by an exponential function ; a similar relation also exists in the case of γ-rays. Regener considered that the primary radiation as in the case of γ-rays is electromagnetic in nature. This view has found support by the work of Millikan, and his collaborators. Millikan considers that practically all the residual ionisation is due to electrons (positive and negative) rather than to other heavier nuclei ; that about 80 to 90 per cent. of the ionisation is due to the secondary electron rays produced within the atmosphere by the incoming photons and electrons ; that there is no evidence that anywhere on the earth more than 2 per cent. of the ionisation found at sea level is due directly to the incoming electrons which is responsible for the latitude and the East-West variation of the intensity of the ionisation ; that the earth's magnetic field separates the incoming secondary electrons with low energy from those with high energy, allowing the former to concentrate near the poles and the latter, which have an excess of positive electrons, to concentrate at the equator and that the greater part of the ionisation of our atmosphere is due to photons with an energy of the order of 200 million electron-volts. In the year 1929, Bothe and Kolhorster, by employing a double Geiger counter arrangement so arranged that the ordinary radioactive radiations could not discharge both the counters simultaneously, adduced evidence to show that the cosmic rays consist of high velocity electrons. Bothe and Kolhorster found no variation of the intensity of ionisation with respect to the latitude between Hamburg and Spitzbergen, while Clay had found a decrease of the intensity of ionisation near the Equator in his geographic investigation of the cosmic ray intensity between Holland and Java. The extensive geographic study of the ionisation intensity organised by Professor A. H. Compton in several parts of the world have however shown that there is a genuine *geomagnetic* latitude effect, an East-

West effect and an altitude effect. These results can be very well interpreted according to the theory of the motion of electrons round a magnetic doublet (earth being considered as a magnetic doublet), a theory first enunciated by C. Stϕrmer of Norway, who interprets the origin and forms of *aurora-burealis* and the same theory has been extended by Lemaitre and Vallarta to interpret the asymmetric distribution of cosmic ray intensity on the basis of the corpuscular hypothesis. The investigations of the Italian school led by Rossi gave similar evidence for the existence of the asymmetry. Johnson's investigations on the distribution of the cosmic ray intensity support the corpuscular hypothesis and suggest that the corpuscles should consist exclusively of positrons. Clay has, recently, come to the conclusion that the primary radiation is of corpuscular nature, consisting of electrons, positive and negative, with energy 1-200 million electron-volts, and that this corpuscular radiation produces ultra-gamma photon radiations with energy 10^7–10^{10} *e*-volts. This produces secondary corpuscular radiation with 10^6–10^9 *e*-volts, which in turn produces gamma radiation with energy 10^8–10^7 *e*-volts, which finally produces the corpuscular radiation with energy amounting to 10^7 *e*-volts.

Skobelzyn, Anderson and their co-workers and also Blacket and Ochialini have obtained beautiful photographs of the showers of the corpuscular tracts in the Wilson Chamber. These showers are the paths of the secondary particles diverging generally from a point in the material enclosing the Chamber. Many other aspects of these showers have been examined by other investigators.

The question of the fluctuations in the intensity of cosmic radiation, has attracted a good deal of attention. In the year 1927, Hoffmann discovered the occurrence of sudden bursts of ionisation at certain times. This phenomenon was disputed by the workers of the Millikan school who attributed it to the discharge of the battery in the instrument employed for recording the ionisation. Swann and Compton have shown that Hoffmann's observation was not due to the battery, and more recently Hoffmann has shown that the phenomenon is genuine and is really fundamental. Dr. and Mrs. Montgomery investigated the dependence of the Hoffmann Strosse on the altitude and on the thickness of the material of the ionisation chamber. When the number of the ions are of the order $\cdot 5 \times 10$[illegible], the rate of occurrence of the bursts at Swarthmore (61 m.) was 0.4 per hour while it was 200 per hour at Pike's Peak (4300 m.). When the number of ions is greater, of the order 1.5×10[illegible] they found no appreciable difference in the frequency of occurrence between Swarthmore and Pike's Peak. They also found that the bursts increased with the thickness of the shielding. Thus this new kind of very penetrating radiation, coming in from outside, possesses many new and interesting properties.

October 1935. SECTION B.—K. RAMIAH AND S. RAMANUJAM : *Chlorophyll Deficiencies in Rice* (Oryza sativa).—Nine types of Mendelian chlorophyll deficiences consisting of both unicoloured and variegated forms have been described and their inheritance discussed. Some of these like the "zebra-marked," lutescent, and certain variegated forms are recorded for the first time in rice. N. L. SHARMA AND S. PURKAYASTHA : *The Heavy Minerals of the "Erinpura" Granite and Microgranite of Danta State (N. Gujrat).*—Twenty

specimens of granite and six of microgranite from the main exposures of the "Erinpura" rocks have been analysed from their heavy minerals. M. DAMODARAN AND M. SRINIVASAN: *Ascorbic Acid (Vitamin C) Content of Some Indian Plant Materials*.—The ascorbic acid contents of a number of indigenous plant materials have been tabulated. The Indian gooseberry gives the highest reducing value by the Tillmann-Harris technique among the materials examined (See *Curr. Sci.*, 1935, 3, 353). B. N. SINGH: *The Correlation between Life Duration and Respiratory Phenomena*.—The study of the respiratory index of short-lived and long-lived plants has revealed characteristic differences between the two classes of plants. In the short-lived plants, the index decreases for an early phase of the fourth cycle, the rate of fall becoming more pronounced before the initiation of the reproductive organs. In the long-lived plants, on the other hand, the rate is more or less steady and shows a stop only towards the end of the growth cycle. J. DAYAL: *Studies on the Trematode Parasites of Indian Fishes I*.—A New Trematode, *Monorchotrema taakree* n. sp. from a Fresh Water Fish, *Pseudeutropius taakree*, from Lucknow.—A trematode of the family Heterophyidæ found as an adult in the intestine of a fish (*Pseudeutropius taakree*) has been described. S. B. KAUSIK: *The Life-History of* Lobelia trigona *Roxb. with Special Reference to the Nutrition of the Embryo-Sac*.—The nutritive mechanism of the embryo-sac has been described.

University and Educational Intelligence.

Annamalai University:

1. *The Founder's Day*.—The Sixth Founder's Day was celebrated on the 12th October, 1935, under the presidency of the Right Hon'ble V. S. Srinivasa Sastri, P.C., C.H., LL.D., Vice-Chancellor of the University. Captain M. Abdul Hamid, M.A. (Oxon.), Principal, Government Mohammedan College, Madras, delivered the Address.

2. *Convocation*.—On the 31st October, 1935, the Fifth Convocation of the University for conferring degrees, diplomas and titles was held when His Excellency Lord Erskine, G.C.I.E., Governor of Madras and Chancellor of the University, presided. Sir Mirza M. Ismail, KT., O.B.E., Dewan of Mysore, delivered the Address to the graduates. 103 candidates were presented at the Convocation besides 41 who took their degrees and titles *in absentia*.

An ordinary meeting of the Senate was held on the same day at 3 P.M. The following resolutions moved by Mr. G. Srinivasa Ayyar were adopted :—

i. The Senate recommends that a Bureau of Information of careers for graduates be opened at the University to provide facilities for the employment of the graduates.

ii. The Senate resolves that an official register of the graduates of the University be maintained and revised every year to give particulars of their address, employment and achievements.

The Senate also approved of the proposal of the Syndicate to institute for a period of 3 years a teaching post in the grade of a lecturer for the Department of English, in view of the large number of students admitted this year and the additional work entailed thereby.

3. *Special Lectures*.—On the invitation by the Syndicate, the following persons delivered courses of special lectures during October, 1935;—

Dr. H. Parameswaran—3 lectures on "Vacuum Technology." Prof. P. Sambamurthy—4 lectures on "South Indian Music," with an Orchestral Concert on the 2nd November.

4. *Library*.—The University Library has been re-organised with a view to making it more useful to the staff and students. Provision has been made for a spacious reading-room and arrangements have been made for the Library to work from 7 A.M. to 7 P.M. on all days of the week including Sundays.

5. *Inter-Collegiate Debate*.—Under the auspices of the University Union, an inter-collegiate debate was held on the 19th October in which representatives of the Madras Colleges (Presidency, Christian, Pachaiyappah's and Loyola) participated. The subject of the debate was:

"That Science can achieve the moral well-being of humanity more effectively than religion."

Messrs. C. Jagannathachari of the Annamalai University and K. Rangachari of the Christian College, Madras, were adjudged the best speakers and awarded a prize each.

Under the auspices of the Sanskrit Society, M. R. Ry. K. Balasubrahmanya Ayyar Avl., B.A., B.L., Madras, delivered the Inaugural Address. The occasion was availed of to have the portrait of Mahamahopadhyaya Vidyavachaspati S. Kuppuswami Sastriar, M.A., I.E.S. (Retd.), Professor of Sanskrit and Comparative Philology, Presidency College, Madras, unveiled by the Vice-Chancellor.

6. *Talks on Popular Subjects*.—A system by which a member of the Staff gives a talk to the students every week or a fortnight on a subject of popular interest, was inaugurated in September last by the Vice-Chancellor.

The following members of the Staff gave talks on the following topics:

The Vice-Chancellor: on "The Italo-Abyssinian dispute."

Prof. M. S. Sundaram: on "The Far East."

Mr. V. R. Viramani: on "The Sanctions."

7. *Elections*.—The Elections to the several University authorities that are now being reconstituted are in progress and the new bodies will function from 6th December 1935.

Andhra University:

The following candidates have been qualified to receive the degrees noted below :—

Doctor of Philosophy: A. Veerabhadra Rao, M.A. Title of Thesis: "Studies on Raman Effect." I. V. Radhakrishna Rao. Title of Thesis: "Sirrhosis of the liver in Northern Circars."

Master of Science: Mr. D. S. N. Murti, B.A. Title of Thesis; "Isomerism in Organic Chemistry."

REVIEWS.

La Spectroscopie Appliquée. Par P. Swings. (Paris: Hermann et Cie, 1935). Pp. 188. Price 15 fr. Paper Cover.

The most important practical application of spectroscopy is to be found in the analysis of the chemical constitution of the source of radiation and has had spectacular success in giving information about the heavenly bodies. The more mundane question of the determination of the chemical constitution of different chemicals, alloys or minerals is no less successfully attacked by the methods of spectroscopy. Its greatest utility is due to the fact that constituents present in very minute quantities can be detected and the amount of the substance required for the analysis is also small. Local examination of intrusions in a metal, etc., is another domain where spectroscopic methods are supreme. Though qualitative analysis has been known to be a commonplace application for a long time, it is only recently that methods of quantitative analysis have been giving reliable results. Nowadays, however, many industrial laboratories employ spectro-analytical methods on account of their sensitiveness, rapidity and small demand on the amount of substance necessary. The book under review has been written by one who has made contributions to the study of band spectra. It is an admirable resumé of the methods of qualitative and quantitative spectro-analysis. The most recent researches have been taken into consideration and the practice made quite clear by definite instructions. The rationale of the methods, their advantages, fields of application and limits of error have been well discussed so that a careful choice of the most suitable technique in any case will be easy for any one who seriously studies the book. The discussions and instructions are always brief but clear and to the point. A number of tables not given in the book would be required in practice but the bibliography in the book makes it quite easy to find the required information. Applications to Biology and Medical Jurisprudence are touched upon and in the end a very brief summary of the theory underlying the unravelling of atomic and molecular spectra is given. With occasional reference to the larger treatises mentioned in the text, the volume will serve as an admirable handbook for the industrial spectroscopist.

T. S. S.

Optical Rotatory Power. By Professor T. Martin Lowry, C.B.E., M.A., D.Sc., F.R.S. (Text Books of Physical Chemistry.) (Longmans, Green & Co., Ltd. London, New York and Toronto.) 1935. Pp. xiii + 483. 30s. net.

Professor Lowry and all chemists interested in optical rotatory power are to be congratulated on the appearance of this excellent book. It is a landmark in the study of optical activity, and is a record of work and progress in polarimetry, extending over a period of 120 years, from the original discovery of the optical rotatory power of Quartz by Biot in Paris (1813) to the recent theoretical work of Max Born in Cambridge, which has at last provided an adequate physical basis for the interpretation of one of the most difficult of optical phenomena.

Part I, Historical and General, besides describing the pioneer work of Biot and Fresnel, includes the epoch-making researches of Pasteur on Molecular Dissymmetry as well as those of Le Bel and Van't Hoff, which provided a firm foundation for the Science of Stereochemistry. This section also records the work of Pope and Werner. On the physical side, an account is given of Biot's Law of Inverse Squares, with its subsequent modifications culminating in the well-known formula of Drude, which suffices to express the rotatory dispersion of transparent media of all kinds with remarkable precision. Cotton's discovery in absorbing optically-active media of the twin phenomena of circular dichroism and of anomalous rotatory dispersion is also included. One of the most important phenomena of optical activity, namely, the Asymmetric Synthesis is also treated. The successful experiments of Freudenberg, Kuhn and Braun in realising for the first time, the preparation of an optically active compound under the influence of circularly polarised light is dependent on the utilisation of Cotton's discovery of circular dichroism. Just as Wohler's synthesis of urea shook the belief in the old vital force theory of the preparation of organic compounds, so, by the artificial making of a one-sided optically active substance in excess, a further advance is made on the road linking organic with inorganic nature. The significance of these results is enormous: they show that in principle no vital force is necessary for the

production of optically active compounds and thus refute Japp's dictum that "the absolute origin of compounds of one-sided asymmetry to be found in the living world is a mystery as profound as the absolute origin of life itself." The section closes with an account of Magnetic Rotatory Power and its application to studies of the chemical constitution of organic compounds. It is to be regretted that a very important and puzzling phenomenon of optical activity, the Walden Inversion, is left out and it is hoped that this omission will be rectified in a second edition of the book.

Part II, Polarimetry, is a very complete record of the development of polarimetric apparatus for the measurement of rotatory dispersion in the visible, ultra-violet and in the infra-red regions of the spectrum. The last chapter in this section is devoted to the measurement of circular dichroism, the significance of which is already pointed out in the foregoing paragraph. This section will doubtless be found very useful to workers in this field of optical investigations.

Part III, Special Cases, records the application of polarimetric methods to the study of the following substances: quartz, amyl alcohol, *iso*-valeric acid, tartaric acid, malic acid, lactic acid, sugars, camphor, borneol, nicotine, and some of Werner's coloured co-ordination compounds. This section also treats of a number of important problems of general interest, *e.g.*, Hudson's "iso-rotation rules", the phenomenon of muta-rotation, discovered by Dubrunfaut in 1846, anomalous rotatory dispersion and circular dichroism. The author has drawn largely from data published by himself and his students.

Part IV, Theoretical Considerations, gives an account of optical rotatory power of crystals, "liquid crystals" and solutions. This section is, however, devoted mainly to recent work on rotatory dispersion in transparent and absorbing media with a view to express the magnitude of their optical activity by means of mathematical equations. Kuhn, Gray, de Mallemann and Boys have attempted to co-relate optical activity with other optical and chemical properties of a substance by using different methods. Boys finds a rather simple expression for the rotatory power, which contains nothing else but the refractivities and the effective radii of the chemical groups involved. This theory cannot explain the fact that a strong absorption band may make a very small contribution to the optical activity and *vice versa*. "The real theory of optical rotatory power may be found by the mathematician, but is concealed from the chemist, in the papers of Born" says Prof. Lowry, "who recognised that *four* coupled electrons are required to produce optical rotatory power." A survey of Born's theory is included.

The book is well printed and illustrated. The number of mistakes is indeed very small in a book which contains so much matter.

BAWA KARTAR SINGH.

Elementary Electricity and Magnetism. By N. Robert W. Hutchinson, M.Sc. (University Tutorial Press, Ltd., London.) Pp. 475. Price 6/6.

In this excellent volume Mr. Hutchinson has set forth with great lucidity the elements of Magnetism, Static and Current Electricity. Within less than 500 pages of large print, the author has provided a wealth of theoretical and practical information that will more than cover the average Intermediate syllabus in India. In addition—and this constitutes the greater value of the book—he has brought the matter right up to the minute almost, by including brief but simple and clear accounts of the latest developments, *in theory and practice*, of physical science. The student of science as well as the "man in the street" hears so much about these developments that his curiosity is naturally aroused. In this book he can learn a good bit about X-rays, Wireless, Atomic theory, Transmutation of the elements, Radio-activity and even Television!

There are innumerable text-books for those who desire to learn just what is needed for examination purposes but here is a work which must be read by all students—if only for the stimulation of that curiosity which has been the foundation of most great discoveries in the past.

P. A. M.

Notes on Organic Chemistry. By F. Francis, Ph.D., D.Sc., F.I.C. (E. Arnold & Co., London, 1935.) Pp. 518. Printed on one side. Price 12*s.* 6*d.*

These notes have been written for the advanced students in the Honours Schools with a fairly sound background of organic chemistry.

In the Introductory portion such diverse

subjects as Theories of Radicals, Concepts of Valency, Isomerism, Rise, Growth and Development of Stereochemistry, Strain Theory, Tautomerism, Applications of Physical Methods to problems of Organic Chemistry, etc., have been dealt with in the space of 42 pages printed on one side. One cannot help feeling that the treatment is cursory and the value of the work is greatly diminished by absence of references to the original papers of the authors cited. For example, the subject of Infra-red Spectroscopy is dismissed in five lines without any reference even to the outstanding papers on the subject. It is doubtful if such treatment would serve any purpose except in merely informing the reader that Infra-red Spectroscopy is one of the methods used in the determination of the configuration of the molecule. Similarly the important subject of dipole moments does not receive any better consideration.

The book is badly revised as numerous serious errors of formulation occur throughout. It is particularly noticeable in Chapter II where the formulæ on p. 66 under 27, on p. 82 under II, on p. 84 under 21 and under III, on p. 86 under 23 are but examples of many similar errors.

The reviewer had some difficulty in understanding the logic of the arrangement of the subjects. It seems that a mass of facts are grouped together without a definite plan. Perhaps some consolation is to be found in the fact that the book is intended to be nothing more than mere Notes—a *vade mecum* for an aspiring organic chemist.

The author has not often been successful in stimulating the interest of his readers. For example, under phenyl hydrazine (p. 496), the three reactions that appealed to him are (*a*) the indole condensation, (*b*) pyrazolone formation, and (*c*) reducing action of phenyl hydrazine. The indole condensation is dismissed with the statement, p. 498: "To a certain extent the reaction is general although its mechanism is not clear". No references, of course, are given to Robinson's work on the mechanism of indole formation or Reddelin's work.

Notwithstanding the defects, the book contains a lot of useful information which would be of help if the reader finds out the proper references himself and makes notes of them in the alternate blank pages provided.

The Chapter on additive reactions of unsaturated compounds gives a useful summary of the recent work on the subject.

One wishes "The Diene synthesis" had been a little more fully dealt with although the account given is excellent in many ways.

The book would be serviceable to the advanced students of chemistry. It is hoped that in the second edition the proofs would be better corrected and references to the original papers would be given where necessary.

J. N. R.

Introduction to Vertebrate Embryology. By Waldo Shumway, Ph.D. (John Wiley & Sons, Inc. New York, 1935.) Pp. xii+390. Price 20*s*. net.

The III edition of W. Shumway's *Introduction to Vertebrate Embryology*, is an addition to the literature in the field of Embryology. As the author rightly points out Embryology is not an easy subject, for the student must possess a capacity to imagine the changing conditions of the embryo and thus mentally reconstruct a three-dimensional picture of the embryo from stage to stage. The book is divided into five parts and each part contains a large number of chapters and each chapter concludes with a concise summary and a list of the more important reference papers. Part I, besides giving a brief account of the genesis of the study of Embryology, also describes the life histories of chordates like Amphioxus, Frog, Chick and Man in a very elementary way. The next two chapters deal with early Embryology and Organogeny. In Chapter IV on Chromosomes and Genes, brief descriptions are given of the Sex chromosomes, Linkage, Crossing over, Chromosomal aberrations, etc. Embryonic form and extra embryonic structures is the subject-matter of Chapter VI. How the form of the body is to a large extent governed by the shape of the gastrula as well as the extra embryonic structures is described. In describing the yolksac, it is said (p. 136) that "In other mammals (Fig. 68) the endoderm grows completely around the interior of the trophoblast and forms a larger yolk-sac." How about the yolksac in forms like Cavia where the distal wall is absent? It may be noted here that Fig. 6 refers to a sagittal section through early gastrula of pigeon. We feel that the author should have described in greater detail the formation of amnion in mammals and discussed the nature of the amniotic cavity in forms like guinea pig and Primates. On

p. 144 in a short paragraph on the "Allantois of man and other mammals," the author points out that "In most of the mammals there is a well-developed allantois, arising like that of the chick.... but the human allantois is rudimentary." A knowledge of comparative embryology tells us that no doubt the allantois arises as in chick and is well developed in mammals, but certainly as a rule in Primates (including man), it is rudimentary. A serious mistake is committed by the author in the paragraph on "The Placenta" (p. 145). It is said that "In Perameles (Fig. 93 B), an allantoic hemiplacenta is formed by the union of the allantoic sac with the trophoblast. Where this hemiplacenta touches the mucosa the epithelium of the latter thickens and is invaded by maternal capillaries. The trophoblast is said to be resorbed so that the capillaries of the allantois come into intimate connection with those of the uterus." When we say that the "epithelium of the latter thickens" it obviously gives us an idea that the cells increase in size and thickness, but really the cells become syncytial and again, the trophoblast is never resorbed, for it unites to form a large syncytial layer with the uterine mucosa. The next chapter on Experimental Embryology is interesting. The well-known rule that development is epigenetic is stressed ; and given a suitable inheritance of genes and a favourable environment, it is noted that development proceeds normally. Development ceases due to overdosage of Ultra-violet light, X-rays or radium emanations. A reference is also made to the works of Müller in describing the influence of agencies like X-rays, etc., on the rate of mutation of Drosophila genes. Part IV dealing with the anatomy of vertebrate embryos like Frog, Chick and Pig, assists the student in identifying parts easily. A good account of the various methods used in embryological studies for preparing slides by the ordinary and celloidin methods, reconstruction are clearly described in Part V. A glossary of nearly 15 pages is also given.

The get-up of the book is excellent and the book should find a place in the library of every embryologist.

R.

Forest Research in India, 1933-34. (Manager of Publications, Delhi.) Parts I and II.

A perusal of this booklet makes interesting reading both to the layman and to the scientist. Part I which deals with the Forest Research Institute, Dehra Dun, is of more general interest and gives one an insight into the progress being made from year to year in the more technical aspects of Forestry. Further advances are recorded in Silviculture, particularly with regard to Sal, in statistical methods, in Botany, Mycology and on the economic side.

The study of "Spike" in Sandal has reached a stage when certain definite results can be confidently expected and it is therefore all the more regrettable that the experiments have had to be closed down for lack of support from the Madras Government. Interesting and conclusive results have been reached with experiments in sleeper seasoning and stacking, and a new and improved method of kiln-seasoning has been perfected. In this connection it is interesting to note that Deodar sleepers in the Punjab are to be treated with a wood preservative before use while, on the other hand, the soft-wood sleeper treating plant in Assam has been closed down for lack of support from the Railways concerned ; this latter must mean a heavy blow to the marketing of the Upper Assam soft-woods. A heartening feature, however, is that soft-wood veneers from this area are gradually establishing themslves, particularly in the tea-trade. A notable achievement on the side of wood-preservation, has been the patenting by Dr. Kamesam of the "Ascu" process : a logical development of the Falkamesam process, by which both Arsenic and Copper are "fixed" in the wood. This will mean a considerable reduction in the cost of preservation with an increased degree of protection, although a supplementary impregnation with oil, to prevent splitting, will apparently be necessary. The technique for testing wood-preservatives has also been considerably improved upon marking a distinct advance on the old "graveyard" methods. Investigations into pulp-manufacture have also been continued with satisfactory results.

Turning to the Provinces, we find an extension in the Andamans of the new method of naturally regenerating mixed deciduous forests by removal of the cover from below upwards.

Assam is making steady progress in the regeneration of Sal, in spite of the inroads of Eupatorium and it is becoming increasingly the suspicion of some foresters there that the presence of grass is not absolutely necessary for the production of regeneration,

and that the latter would appear to be largely dependent on certain soil-factors. The working plan for the Evergreen forests of Upper Assam has been brought practically to a stand-still by the closure of the soft-wood sleeper-treating plant.

Bengal continues to experiment with the regeneration of Garjan (Dip. Spp.) and Sal; the latter continues to be the main problem in Bihar and Orissa and the U. P. In Burma stump-planting of teak and the influence of the origin of teak seed on growth and quality continue to demand attention, while in the C. P. the new systems of coppicing adopted in place of the selection and improvement systems have not produced entirely satisfactory results in the best teak forests. In Madras teak again is the species receiving most attention, and valuable results appear to have been obtained in planting and tending. In the Punjab Blue Pine regeneration continues to be difficult, while the Sal problem in the U. P. remains at a stand-still.

Coloured Plates of the Birds of Ceylon. By G. M. Henry. With a short description of each bird by W. E. Wait, C.M.G., M.A., F.Z.S., ETC. Part IV. 16 coloured plates. (Published by the Ceylon Government, 1935.) Price £1–10–0.

There is a Chinese proverb which says that a single picture is worth more than 10,000 words. Nowhere is its application truer than in the case of bird study in India, for one of our greatest handicaps is the paucity or almost complete lack of good illustrations of Indian birds. Not that we have a plethora of bird books; indeed the very opposite is the case, but without pictures bird books would be of little use to the beginner or the layman. Pictures to be really helpful must be coloured, and pictures to be coloured are necessarily costly, and to come back to our starting point in this vicious circle, it is the costliness of colour printing that has so retarded the publication of popular bird books in this country and acted as dead weight against the advancement of this fascinating study.

An effort has indeed been made in recent years to overcome this drawback, and the beautifully illustrated books on the Game Birds of the Indian Empire by Stuart Baker and the set of 5 wall charts depicting about 200 species of the common birds of this country, published at great expense and considerable financial risk by the Bombay Natural History Society, and the *Popular Handbook of Indian Birds* by Hugh Whistler are the foremost examples.

Under the circumstances these coloured plates of the Birds of Ceylon are more than welcome, and the Government of Ceylon is to be congratulated not only upon its enterprise in undertaking their publication, but also upon its discovery of an artist of the accomplishments of Mr. G. M. Henry, an assistant in the Colombo Museum. It is not every artist, however masterful he may be, who can give a pleasing, accurate and lifelike rendering of a bird unless he is at the same time a naturalist and thoroughly familiar with his subjects *in life*. Mr. Henry obviously combines in himself both these attributes, and the plates which are the result of this combination are a real pleasure to behold.

In artistic merit, Part IV which is now before us, fully maintains the high standard set by its predecessors. It contains 16 plates, seven of which depict Passerine species, the remaining nine illustrating various non-Passerine forms.

It is perhaps unfortunate that while illustrating both the male and the female of the Ceylon Red-vented Bulbul, a species in which the sexes do not differ at all in colouration, only the male of the Ceylon Magpie Robin should have been shown. In the Indian race of this bird the black upper parts of the male are ashy-brown in the female, while the black in his lower plumage is replaced in the female by ashy-grey. In the Ceylon race the female is darker both above and below and sometimes indeed so dark that the correct sex can only be determined by dissection. Normally, however, there is sufficient dimorphism to have justified an illustration. We notice that Mr. Wait has attempted to supply this deficiency in his letter-press.

Sundry minor defects of undue accentuation of certain colours or *vice versa* are more or less inevitable in printing of this kind—for example there is too much blue in the back of the female Orange Minivet—but on the whole the reproduction of the plates is commendable.

The short descriptions of the birds by Mr. W. E. Wait, to whose well-known *Manual of the Birds of Ceylon* these plates are meant to be supplementary, touch upon the salient points in the distribution and habits of each species, but in our opinion measurements given in inches and such irritating decimals as "0·7" for example, are an

anachronism that is thoroughly inexcusable in a modern work even of a popular-*cum*-scientific nature. We cannot help thinking that the present work suffers appreciably in scientific value from the adoption of the inch as the unit of measure rather than the more rational and universally accepted millimeter.

The ultimate scope of the work is unknown so we do not know how many further parts to expect. We can only hope, however, that we may still look forward to many more of Mr. Henry's beautiful drawings and that the Ceylon Government will continue its useful and munificent work of sponsoring a publication, which, by the very nature of its sumptuousness, they cannot perhaps look upon as likely to prove a financial success.

S. A. A.

Biochemical and Allied Research in India, 1934. (Published by the Society of Biological Chemists, India. Bangalore Press, 1935.) Pp. 107. Price Re. 1.

The Society of Biological Chemists, India, has just issued its annual publication *Biochemical and Allied Research in India, 1934*. At the moment, this publication is the only one of its kind in giving us, at least in part, a measure of the chemical research carried out annually in this country. We wish that other Societies will emulate this example in publishing such annual reports in other branches of chemistry as well. For this purpose, the birth of the National Institute of Sciences and the Indian Academy of Sciences is a very happy augury.

In the present publication, the fifth in its series, the reviews on different aspects of biochemistry, written presumably by experts in the field, are exhaustive without being critical. This tendency on the part of the reviewer to be complete has resulted in a repetition of themes. Thus the work on nutrition is dealt at length in three different sections, though there could be only one place for it. It is a little amusing to read about problems of fruit preservation being discussed in a section on animal husbandry. It was possible, as in the previous years, to have presented the matter more systematically. The publication afforded the best opportunity to the Society of Biological Chemists to have offered felicitations to its two sister-Societies—the Indian Society of Soil Science and the Indian Physiological Society—started during the year.

Despite the best endeavour on the part of the reviewers to include every reference, a few have escaped notice. Being at the mercy of the belated foreign chemical abstracts for getting at Indian work, the authors of the review could not have done better. But there can be no extenuating circumstance for certain flagrant omissions, as, for instance, of the publications of the Indian Lac Research Institute, Ranchi.

The section on Agricultural Chemistry, which could have started with acknowledgments to the Imperial Council of Agricultural Research for the researches sponsored by it during the year under review, rightly claims the largest space in the publication. The researches, discussed in this section, are those carried out in the various Government Agricultural Departments, including "quake-striken" Pusa, and in the Department of Biochemistry, Indian Institute of Science, Bangalore. A finding by the last-mentioned Department, of special interest to the farmer, is the value of oxidising agents as fertilisers, resulting in one instance in a phenomenal increase of one hundred per cent. in the yield of tomato. Whether this finding, now having only a cloistered virtue, is capable of wide application in agricultural practice, is a matter deserving the attention of some co-ordinating scientific body. On another page of this section is described the work of Dhar and co-workers on the photo-chemical transformations in the soil wrought by metallic oxides, facilitating the oxidation of the organic constituents of the soil. Whether this is the cause of the phenomenon, of which the fertilising value mentioned above is the effect, is a question that an inquiring reader of the review is tempted to ask its author.

As with agricultural chemistry, the work reported in other sections of the publication is that carried out mostly in the different Government Departments. These departmental researches, being planned to meet special needs, are necessarily limited in their scope. In relief, stands the section on "Enzymes". The pure biochemist will still miss in this avowedly biochemical review of India a chapter on general biochemistry devoted to problems of fundamental interest. It is hoped that such a section, with the facilities and workers available in the country, will form the most conspicuous feature of the coming publications.

A short sectional title on each page and a subject index at the end would have

greatly added to the usefulness of the publication.

M. SRINIVASAN.

The Indian Sugar Industry. Lecture delivered by B. C. Burt, C.I.E., M.B.E., B.SC., I.A.S., Expert Adviser, Imperial Council of Agricultural Research, Journal of the Royal Society of Arts, 1935, **83**, 919.

In a paper with the above title, B. C. Burt has traced briefly the development of sugar industry in India. The author has pointed out that India can be regarded as the original home of sugarcane and prior to the grant of fiscal protection to Indian sugar industry, India was still in the anomalous position of being at the same time the world's second largest grower of cane and one of the greatest importers of manufactured sugar. Within four years after protection the output of factory sugar increased enormously and it is expected to meet the whole of Indian demand shortly. Organised efforts at establishing the modern sugar industry in India date from the year 1910. The work of Mr. Moreland in arranging for a demonstrative miniature vacuum pan factory, the specific recommendations of the Board of Agriculture in India and the Government's prompt action on them have been outlined. The author then has surveyed the progress made since 1911 and has sketched the achievements of the Coimbatore cane breeding station [illegible] the guidance of Dr. Barber. The work [illegible] Indian Sugar Committee (1919–20) [illegible] contributions by Rao Bahadur [illegible] raman to our knowledge of cane [illegible] have been mentioned, the latter in [illegible] what great detail.

The rest of the paper is devoted [illegible] development after the year 192[illegible] formation of the Imperial Council of [illegible] cultural Research in 1929, the Tariff [illegible] enquiry and the grant of protection [illegible] are all briefly described.

The paper concludes with a mem[illegible] the effects of Bihar earthquake a[illegible] possible future of Indian Sugar In[illegible] followed by a critical discussion.

This paper on the whole is a good [illegible] of the historical development of [illegible] sugar industry in India but the auth[illegible] not touched some of the main p[illegible] confronting the future of the indust[illegible] has amply dealt with the progress [illegible] the agricultural side and describ[illegible] achievements of the Coimbatore [illegible] mental station in improving the raw ma[illegible] Besides the very important problem [illegible] material, the problem of utilising ec[illegible] cally the by-products of the in[illegible] especially molasses, is also looming [illegible] Topics of such vital interest must hav[illegible] dealt with in the paper.

The Zoological Survey of India.

WE have read the triennial report of the Zoological Survey of India for the years 1932–35 with considerable interest. This document recently issued by the Director presents in a concise and readable form the principal activities in which the departmental officers were engaged during the period covered by the report, and also indicates how the curtailment of grants has affected the progress of investigations. The work of the Scientific Surveys and the knowledge which they advance deserve the attention of governments and also of the public in greater measure than is generally accorded to them. The researches which they undertake are always of great intrinsic importance and frequently of real practical interest, but almost invariably, the value of scientific investigations is neither understood nor appreciated. Scientific work in India suffers from lack of proper exponents who can interpret its significance and its bearing on the practical problems of life in the language of the people. Many of the discussions initiated in the Indian Legislative Chambers on important public affairs have a scientific background, and decisions reached have frequently no relation to the proper appreciation of the development and the progress of science in its application to practical ends. It is needless to observe that the intelligent understanding and discussion of many administrative problems necessitates a fairly comprehensive knowledge of the scientific principles involved in their theoretical and practical aspects, and in their bearing on economics and politics as well as on social and legislative measures.

One of the ways, in which the work of the Surveys can be brought prominently before the public, is to extend and co-ordinate the existing Scientific Surveys where such co-ordination is desirable, and to establish a Committee of Scientific Advice. If such a Committee is formed on a representative basis, it should accept the responsibility of promoting discussion in the Council Chambers of Federal India on scientific subjects in their application to economic policy and national well-being. It may be necessary to organise periodical addresses by scientific authorities to the principal political parties, and to assist government in all administrative measures and acts involving the application of modern scientific knowledge. An organisation occupying the

status and fulfilling the duties of the Parliamentary Science Committee in Great Britain is already overdue in India, and the sooner we establish a definite link between Science and Government on the one hand, and Science and Society on the other, the sooner shall we secure the orderly progress of knowledge and the continuous improvement of the economic and social condition of the country. One of the most important truths which the Committee will have to impress on the public and government will be that scientific departments differ in their spirit and character from the administrative branches, and that investigations in the former should proceed uninterrupted by the fluctuations of financial assistance. Our civilisation has progressed by the increasing exploitation of the resources of animate and inanimate nature, and the wealth of the world increases in proportion to such exploitation. The reason why the industrialists invest more money in scientific research when their income falls, is that they live in a competitive world. Starving the scientific departments virtually implies extinction of the industry concerned. But governments as producers of wealth have no competitors, and their attitude towards scientific research correspondingly differs. Like all industrial organisations, government ought to find it more profitable to stimulate the means of earning increased revenue through scientific research, than to resort to the hackneyed policy of enhancing taxes during the recurring periods of financial depression. It is this aspect of administrative policy that the Committee of Scientific Advice that we have proposed should inculcate in the mind of government and the public. Until the political parties realise the imperative necessity of the substitution of such a financial doctrine in the place of the one now pursued, Scientific Surveys are liable to inhibitions of grants.

In the opening paragraph of the report the Director of the Zoological Survey observes that, as a consequence of the scheme of retrenchment applied to his department, the field investigations by the officers were greatly restricted, important research activities curtailed and the staff reduced to a maintenance basis. However the achievements of the Survey during the period reported, form an impressive record comparable with any previous term not affected by financial stringency. This was rendered possible by the unstinted devotion to work already in progress, but there must, however, be a limit to the exertion of unrelieved energy and enthusiasm. The improvement in the financial position of the Government of India offers hope that the grants to the Zoological Survey will speedily be restored to the original scale, without which the arrears of work must continue to exist, and fresh investigations cannot be undertaken. That the work carried on in the Zoological Survey is of such importance as to be recognised abroad is evident from the fact that two of its officers, Dr. S. W. Kemp and Lt.-Col. R. B. Seymour Sewell, were selected to lead oceanographical expeditions sent out by Great Britain within the last ten years. The wealth of research material and the facilities for investigation of practically every species of problem available in the Survey attract Zoologists from foreign countries, besides large numbers of research workers from the Indian Universities and other scientific institutions.

The main feature of scientific progress is the close and steady co-operation between different groups of investigators, since the discoveries in any branch of science find ready application in apparently unrelated departments of knowledge. We have several research institutions in India equipped and maintained by government subsidies, and prevention of overlapping of effort and of duplication of expenditure is a problem worth consideration. In what directions and to what extent intimate co-operation can be secured so as to save expenditure, and to secure at the same time concentrated action, must be one of the duties of the Committee of Scientific Advice already suggested. There are several directions in which the economy of Government grant and of the effort of investigators could be effected. For instance quite a considerable volume of taxonomic work in entomology is done at the different agricultural and forest research institutions in India, and also under the auspices of the Medical Research Fund Association. It would be advantageous, and in certain respects even necessary, to centralise this department of enquiry, as far as possible, at a single institution possessing the requisite laboratory and library facilities, and adequate reserve collections for comparative study. The experience and knowledge of the officers of the Survey and of the members of the subordinate staff when co-ordinated with those working in other research institutes should prove an invaluable implement for the elucidation of problems in which field

work forms the basis of all entomological investigations. Extension of the Entomological Section of the Zoological Survey of India would appear to meet all the demands, provided it gains affiliation and co-ordination of the work carried on in the different centres in such fields of investigation as co-operation would advance. Similarly for the more intense ichthyological research in India, the Fish Section of the Zoological Survey of India could be strengthened to considerable advantage, to which the fisheries departments in the provinces might contribute their experience and knowledge. We are not thinking of the centralisation of research, but only examining the possible advantages of creating a central body where problems in economic zoology could be investigated from a broader and comparative standpoint, and in the elucidation of which the provincial research institutes could honourably cooperate. What we want is research *rapprochement*. This is gradually being established by the Zoological Survey in undertaking detailed investigation in connection with the shell fisheries in the Andamans and their economic exploitation ; the identification of the animals of economic importance from the medical or sanitary point of view for the Calcutta School of Tropical Medicine, the Forest Research Institute, Dehra Dun, the Imperial Institute of Veterinary Research, Muktesar ; the identification of the human and animal remains excavated at Harappa, Mohenjo-daro and other chalcolithic sites in Sind, and the anthropological work connected with the last Census operations. On account of retrenchment, the survey officers have been assigned work which ought to be properly entrusted to the members of subordinate staff, and if they are released from the routine business, they ought to be able to undertake considerably more useful investigations in addition to the legitimate duties connected with their respective office.

The Zoological Survey of India is entrusted with the care and maintenance of the zoological and ethnological galleries of the Museum which in their richness and variety have few parallels in the East. Lack of funds has affected this department quite as seriously as the other sections of the Survey. The official view of the Museum is that it is generally a place for the gratification of the eye, and the message of the exhibits is therefore permitted to remain sub-conscious. It is essentially an educational institution carefully devised for popular enlightenment. It is also a place of reference. Want of proper care and attention due to attenuated staff, and of periodical additions in a bright and attractive form which naturally implies expenditure of money, must rob this section of the Zoological Survey of its power to instruct the visitors and of its usefulness to research students. In 1933, the Director of Zoological Survey was able through the munificence of Dr. S. C. Law to organise an exhibit of storks in a replica of their natural surroundings, and other groups of animals can be exhibited similarly, provided sufficient funds are placed at the disposal of the authorities. In addition to increased grants from governments, the Museum of the Survey should have a large endowment without which further improvements become difficult. The Museum is a great national institution, the usefulness of which is capable of being extended by organising a series of popular lectures on scientific subjects. The presence of foreign scientists who visit the Zoological Survey may be utilised for supplementing the excellent resources which the institution already possesses for inaugurating the scheme of popular addresses in a manner similar to those organised by the Royal Institution of Science and Technology in South Kensington.

The Zoological Survey is now under the direction of Indian scientists and in spite of the limitations imposed by retrenchment, they completed several important pieces of research, and started a large number of interesting investigations during the period under review. It seems to us that in addition to laboratory and field investigations, special branches of research in experimental and economic zoology should be organised when funds become available. No institution in India has such material resources and wealth of experience and knowledge for organising these new departments, as are possessed by the officers of the Survey, and the value of the results of such enquiries for promoting the material prosperity of the country must manifestly be multitudinous. It is true that the work of the Survey is increasing far too rapidly to be handled by the existing staff, and we should be reluctant to make proposals likely to add to their burden. The Zoological Survey is already engaged in important economic problems, but nevertheless the field of investigation is capable of enlargement. Our knowledge of economic ornithology and mammalogy of India is imperfect, and there are gaps in our

information regarding economic pisciculture and entomology. From the triennial report of the Director, we understand that he has submitted to the Government of India proposals for the extension of the department and increase of grants, and, in considering these proposals, we have no doubt that the authorities, while Indianising the services, will also provide them with the necessary means of maintaining their high standard of efficiency and traditional reputation.

Control of Drugs in India.

THE menace of drug adulteration and of traffic in spurious drugs prevalent in India at the present time was the subject of an address by Lieut.-Col. R. N. Chopra, before the Calcutta Rotary Club last month. The speaker showed that the market in India was being flooded by unscrupulous traders with drugs and chemicals of defective strength and impure quality and that potent remedies such as sera, vaccines, gland products and compounds of arsenic and antimony were being freely sold to the public without their quality being tested. The practice was a great menace to the public health and called for prompt institution of efficient safeguards to ensure the quality and authenticity of medicinal preparations offered for sale to the public. There is no doubt that India is *par excellence* the dumping ground for every variety of quack medicines and adulterated drugs manufactured in all parts of the world and that her markets are glutted with useless and deleterious drugs sold by unqualified chemists who are themselves a public danger. That this state of affairs has been going on for some years is shown by the fact that in 1930 the Government of India appointed a small *ad hoc* committee under the chairmanship of Lieut.-Col. Chopra to explore and define the scope of the problem and to make recommendations. The committee started work in October 1930, toured all over India and received a large mass of varied and voluminous evidence both written and oral. It considered carefully and systematically all aspects of the question and in April 1931, made comprehensive and far-reaching recommendations. It is nearly five years since the committee completed its labours and made its report but no action has been taken by the Government and the speaker showed that the position has gone from bad to worse. There is no doubt that all classes of drugs, those belonging to the British Pharmacopœia, those not officially recognised by the pharmacopœia but known and approved medicines including the group of biological products such as sera, vaccines, preparations of animal glands, organometallic compounds, and lastly the group of patent, proprietary and secret remedies are all equally affected. Col. Chopra went into detail of how these different groups were affected and described what was the effect of the substitution of genuine medicinal products by rubbish, which, according to him, has now reached a very serious stage. In diseases such as pneumonia, diphtheria, etc., it may make all the difference to the life of the patient whether he is getting a drug of proper strength or an adulterated or useless preparation. In the case of the complicated organometallic compounds, if they are not properly prepared and tested and in a state of absolute purity, their use will be positively dangerous and fatalities may occur. In the case of biological products incalculable harm may follow the use of products which are improperly prepared or stored. The injection of faked insulin in cases of diabetic coma may lead to the death of the patient. Much harm may result from the use of patent and proprietary and secret medicines in negative as well as positive ways. A patent medicine might be injurious and cause direct harm as in the absence of control some of the constituents may be positively dangerous. Some medicines might have the effect of masking early symptoms of serious and grave diseases and, assuaging them for a short period result in delay of scientific diagnosis and treatment. Col. Chopra performed a public duty of prime importance in bringing to their notice the grave danger the people are running in the absence of control over medicinal preparations. He emphatically pointed out that the Government is morally bound to take steps to rectify the present state of affairs.

The remedy has been suggested by the Drugs Enquiry Committee. The scheme put up by that Commitee, which has been generally accepted as being sound and effective, consists of two parts, namely legislation and the machinery to collect and test drugs. As regards the first part, it is a matter of common knowledge that there is no enactment in the Indian legislature at the present time which aims directly at the

prevention of adulteration or which ensures conformity to proper standards of purity and strength. Although most of the provinces have some sort of legislation, this is generally ineffective; moreover to bring about effectiveness and uniformity of control the legislation should be central and for the country as a whole. This part of the scheme would not entail any monetary expenditure and there is no reason why it should not be proceeded with immediately. Even if mere enactment of legislation by itself is not effective, it will produce a considerable moral effect and in that way will serve as a deterrant. Besides, if this is done time will be saved in future when funds do become available as along with legislation for the control of drugs, legislation, for control of the profession of pharmacy, which in India is still unorganised, will have to be enacted, and consideration of all these and drafting of the bill will naturally take time. The scheme worked out by the Drugs Enquiry Committee for the organisation, registration and training of this profession though it might need a small preliminary expenditure should eventually be self-supporting.

As regards the machinery to test medicinal preparations, this consists of a well-equipped central laboratory with competent staff of experts in various branches as well as provincial laboratories working under the guidance of the central laboratory. This part of the scheme undoubtedly needs an initial outlay and recurring expenditure. In actual practice, however, it will not be necessary to start with the complete scheme as drawn up by the Drugs Enquiry Committee at once so that the expenditure will not be very large in the beginning. The full scheme will take 3–5 years to develop and it will only be necessary to make a modest beginning which will not necessitate very great expenditure. By the time the scheme matures, a certain amount of revenue will be coming in and there is no reason why eventually the scheme should not be self-supporting or very nearly so.

So far as the Provincial Governments are concerned the scheme will also not be very expensive, as alarmists have suggested that it will be. With very little extra expenditure, the existing provincial laboratories could be so strengthened as to undertake the ordinary testing of drugs for the purpose of control. For complicated drugs they will have the central laboratory to utilise. We have no doubt that addition of two or three trained men, with modest salaries, to the existing staff of the provincial laboratories will be all that is necessary to carry out the work which will fall on these laboratories for several years to come. So far as the provision for the inspecting staff is concerned, the Drugs Enquiry Committee preferred the appointment of special drug inspectors not attached to any particular department. If, however, the appointment of these whole-time inspectors is too expensive under the present state of finances, the work can, for some years to come, be entrusted to the inspectors of the Excise Department. Little or no extra remuneration need be given to these officers, while the scheme is maturing the work thrown on them will be very light indeed. Later, when the whole scheme matures and revenue begins to come in from registration, licensing and fees for testing drugs, separate inspectors may be appointed.

The important point emphasised in the Report of the Committee, with which we emphatically agree, is that in any scheme of control the Central Government as well as Provincial Governments must take part. No system of control in which the Provincial Governments do not take their due share along with the Central Government will be feasible, or workable so that the responsibility lies on the heads of both. Public health is a transferred subject and the local legislators will be lacking in their duty if they do not realise their responsibility regarding drug control and let things continue as they are at present.

Isolation and Properties of Pepsin and Trypsin.

By John H. Northrop.

(The Rockefeller Institute for Medical Research, Princeton, N. J.)

ONE of the most striking characteristics of living things is the rapidity and precision with which the chemical changes necessary for their existence are carried on. The process of digestion is a familiar example. Proteins are split in the stomach into much smaller compounds, and this process is continued in the small intestine. The final products are precisely those needed for the nutrition of the animal and are formed from proteins with little or no evolution of heat or expenditure of energy. The process cannot be duplicated without the aid of enzymes since chemical hydrolysis of proteins yields different products and in any case can be accomplished only by violent treatment and the expenditure of considerable energy. Similar examples of the efficiency of the reactions which take place in the animal could be multiplied indefinitely. It is now known that these specific accelerating effects which living cells exert on the reactions occurring within them and in their vicinity are due to the presence of minute amounts of some substances formed by the living cell which have come to be known as enzymes. Without enzymes life could not exist and yet enzymes themselves are not living.

For many years this characteristic ability of living matter to direct these reactions was regarded as a vital activity entirely outside the realm of experimental science. Evidence gradually accumulated, however, to show that the living cell was not necessary, for some, at least, of these characteristic reactions: and one case after another was found in which the reaction could be made to take place without the living cell. But it was not generally admitted that only the enzyme was essential rather than the living cell itself until Buchner discovered that fermentation of sugar could be caused by yeast extract containing no living cells.

It had been suspected long before Buchner that the process of gastric digestion was due to the presence of some specific substance. Schwann in 1836 definitely assumed the existence of such a substance and named it "pepsin". The existence of trypsin in the intestine had also been suspected early in the nineteenth century, but was not definitely assumed to exist until the time of Corvisart (1857) and of Kühne (1867), who gave it its present name. A large number of other enzymes were then discovered by means of their characteristic reactions. It was assumed that since the reactions occur, enzymes must exist to cause them, but there was no direct proof of the actual existence of enzymes, and, in fact, their existence as ordinary chemical compounds has been frequently questioned. The problem is analogous to that of the causative agent of an infectious disease. A causative agent is assumed to exist because the disease occurs, but the assumption cannot be proved until the etiological factor is actually isolated.

During the time enzymatic processes were being discovered the chemists found that many purely chemical reactions are accelerated by small amounts of substances which apparently are not changed by the reaction. Berzelius pointed out that the properties of these substances are strikingly similar to those of the active agents found in living cells. He named the general phenomenon catalysis and considered what are now called enzymes to be a special class of catalysts.

The name "enzyme" was proposed by Kühne for these organic catalysts. In the last fifty years enzymes and enzymatic reactions have been studied intensively by chemists and physiologists. The chemists have been interested primarily in the mechanism of the reactions and the physiologists in the nature of the reactions, and both chemists and physiologists have spent a great deal of time trying to isolate the enzymes. Rapid progress was made in the study of the nature of the reactions caused by enzymes and in many cases the kinetics of the reactions were found to agree with chemical theory but the nature of the enzymes themselves remained quite unknown for many years.

In the last nine years the chemical nature of several enzymes has been determined; urease (Summer), pepsin (Northrop), trypsin (Northrop and Kunitz), amylase (Caldwell, Booker and Sherman), chymo-trypsin (Kunitz and Northrop), yellow respiratory ferment (Warburg and Theorell) and carboxy polypeptidase (Anson) have been obtained in crystalline form. These preparations are all proteins, and this result agrees with

much of the earlier indirect evidence concerning the nature of enzymes. The general chemical nature of these enzymes is therefore known. Enzymes have powerful catalytic properties, however, not possessed by ordinary proteins and hence must possess characteristic chemical structures not found in ordinary proteins. This characteristic chemical structure must be determined before the enzyme problem is completely solved.

ISOLATION AND CRYSTALLIZATION OF PEPSIN.

Nearly all attempts to isolate enzymes have been carried out with relatively small quantities of material in rather dilute solution. Adsorption methods have been extensively used. If enzymes really are proteins, these are not favourable procedures for their isolation, since proteins are extremely unstable in dilute solution and are easily injured by adsorption on surfaces. The attempt to isolate pepsin was undertaken from the point of view of protein chemistry using only those conditions under which proteins are relatively stable, *i.e.*, in concentrated solutions and at low temperature. Purification was accomplished by precipitation with ammonium or magnesium sulphate at various hydrogen ion concentrations and temperatures.

The method was based originally on that of Pekelharing who had described the isolation from gastric juice of an amorphous protein which had powerful proteolytic activity. The last step in Pekelharing's preparation consisted in dialysing a protein fraction from gastric juice against dilute acid. Under these conditions a white precipitate is formed which is a protein and which contains most of the activity. This protein sometimes appears in a somewhat granular form and under the microscope looks as though it might be trying to crystallize. Many attempts were made to crystallize the protein without success. It was noticed finally that this precipitate dissolved if the suspension were warmed to 37° C. and reappeared again upon cooling. These are good conditions for the formation of crystals, and the experiment was repeated under varying conditions and especially with more concentrated solutions, since crystallization in general occurs more readily from concentrated than from dilute solutions. A more concentrated suspension than usual was warmed to 37° C., and the solution was allowed to cool slowly to room temperature in a beaker. The next morning it was found to contain several grams of beautifully formed crystals in the form of double, six-sided pyramids. They were tested for activity and found to be highly active and also to be protein (Fig. 1).

Fig. 1.
Pepsin.

Only small amounts of the crystalline material could be obtained by the original method, but it was found possible to modify it and eventually to dispense with the dialysis which is the most troublesome part of the method. The crystalline protein can now be prepared from commercial pepsin preparations simply by precipitation with magnesium sulphate and then with dilute sulphuric acid. The protein crystallizes very readily, in fact much more readily than most proteins and it is easily possible to prepare 100 gm. in 2 days. A method is therefore at hand by which large quantities of a crystalline protein having powerful proteolytic activity can be prepared. The crystalline enzyme has also been prepared from bovine gastric juice (Northrop). Pepsin prepared from bovine gastric juice differs from, but is very similar to, that from pig gastric extracts. The two enzymes may be distinguished by solubility measurements. It is probable, therefore, that the various pepsins differ from species to species, as do the hemoglobins.

ISOLATION OF CRYSTALLINE TRYPSIN FROM ACTIVE PANCREATIC EXTRACTS.
(Northrop and Kunitz.)

Kühne considered that one enzyme of

the pancreas could hydrolyse protein completely to amino acids and called this hypothetical enzyme "trypsin". He showed that the pancreatic juice itself was inactive and only became active on reaching the intestine. The inactive form of the enzyme was named "trypsinogen". It is now known that the complete hydrolysis of proteins is due to a group of enzymes [erepsin (Cohnheim), amino-polypeptidase, carboxypolypeptidase, protaminase and probably others] so that the original "trypsin" does not exist. The name, however, has always been associated more especially with the enzyme which is activated by intestinal extract and digests proteins (Schepowalnikow). The name "trypsin" has been retained, therefore, to designate what appears to be the most important proteolytic enzyme of the pancreatic juice. This enzyme is present in fresh pancreas in an inactive form, trypsinogen, which is transformed into trypsin by intestinal extract or by allowing the pancreas to stand in slightly acid solution.

The methods used in the isolation of trypsin were, in general, similar to those used in the isolation of pepsin. The raw material was obtained by allowing frozen pancreas to thaw and collecting the expressed fluid. This fluid contained the active form of the enzyme. The problem of purification turned out to be a difficult one, and a great deal of work was done before any encouraging results in the way of either a crystalline product or a product of constant activity was obtained. The most promising method seemed to be precipitation with ammonium sulphate. A protein fraction was eventually obtained which had constant activity and gave some indication of crystallization. The work was made difficult by the very unstable nature of the protein. This unfortunate property made it impossible to allow a solution to stand for more than a few hours, so that the usual procedure for crystallization, which consists in allowing a solution to concentrate or cool very slowly, could not be used. After a large number of unsuccessful attempts, Dr. Kunitz was able to secure definite, regular crystals by the very cautious addition of strong ammonium sulphate to rather concentrated solutions of the protein. The crystals are rather small and are of the cubic system. The proof that this material is a pure substance is still more difficult than in the case of pepsin, since it is more unstable.

Isolation of Chymo-Trypsinogen, Chymo-Trypsin, Trypsinogen and Trypsin from Inactive Pancreas.

The method of isolation described above was laborious and somewhat uncertain since preparations were occasionally obtained which could not be crystallized. It seemed probable that trypsinogen, the inactive form in which the enzyme exists in fresh pancreas, was more stable and hence more easily handled than the active trypsin. The attempt was therefore made to isolate this inactive form of trypsin from fresh pancreas. It was found in the earlier trypsin experiments that the enzyme was remarkably resistant to acid while much of the other protein material present in pancreatic extracts was denatured by acid. Fresh pancreas was, therefore, extracted with strong acid and it was found that most of the inert material remained insoluble while the enzyme was dissolved and extracted. Extraction with strong acid yields a solution which is much more easily purified than those obtained with glycerin, bicarbonate or after autolysis. These latter methods are the ones which have been used in other attempts to isolate trypsin. The results obtained in the present work are largely due to the use of acid extracts. This extract remains inactive indefinitely but is rapidly activated by extract of small intestine (enterokinase) at pH 8·0.

Isolation of chymo-trypsinogen and chymo-trypsin.—The acid extract was fractionally precipitated by ammonium sulphate and a crystalline protein obtained from the fraction precipitated by 0·7 saturated ammonium sulphate (Fig. 2). This protein had no enzymatic activity and could not be activated by kinase. It was considered at first to be merely an inert protein but it was soon found that traces of trypsin would convert the protein into a powerful proteolytic enzyme which differed from the usual trypsin preparation in that it clotted milk. This enzyme probably represents Vernon's "pancreatic rennet" and was called "chymo-trypsin". This active form of the enzyme was also crystallized (Fig. 3).

Isolation of trypsinogen and trypsin.—The mother liquor from the chymo-trypsinogen still becomes active upon the addition of kinase or upon the addition of strong magnesium or ammonium sulphate to a neutral solution, and so still contains

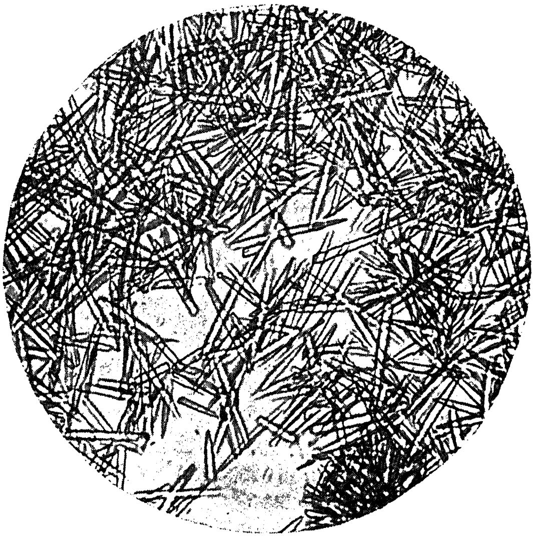

Fig. 2.
Chymo-trypsinogen.

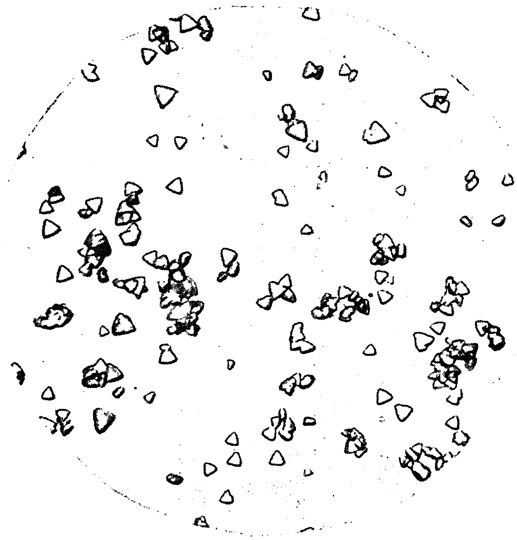

Fig. 4.
Trypsinogen.

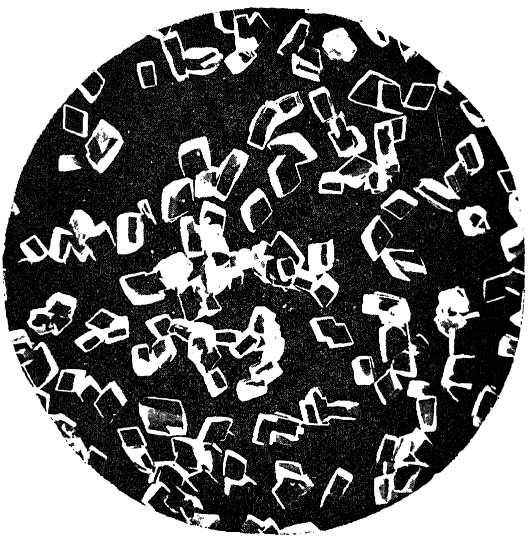

Fig. 3.
Chymo-trypsin.

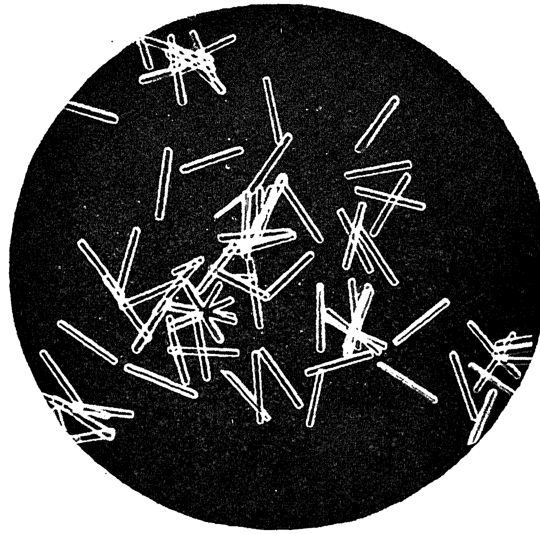

Fig. 5.
Trypsin.

inactive trypsin. The inactive trypsin (trypsinogen) was crystallized from magnesium sulphate solution pH 8·0 at 6° C. in the form of short triangular prisms (Fig. 4). Recrystallization was undertaken and appeared to proceed normally but upon examination the crystals were found to be long square prisms instead of triangular prisms and to be active instead of inactive (Fig. 5). They resembled slightly the crystals of trypsin previously prepared from active material and turned out to be identical with this earlier preparation. Material prepared by the earlier method also crystallizes in the same long square prisms under these conditions.

The transformation of the inactive form of the enzyme during recrystallization is due to the fact that the conditions for crystallization are the same as those for activation. Also, the crystallized trypsinogen activates much more rapidly than does the crude product. This peculiarity is

discussed later in connection with the mechanism of activation.

ISOLATION AND CRYSTALLIZATION OF CARBOXYPOLYPEPTIDASE.

Active pancreatic extracts contain an enzyme which splits certain amino acid compounds in such a way as to liberate an amino acid which, in the intact compound, has a free carboxyl group. This enzyme was named carboxypolypeptidase by Waldschmidt-Leitz. Anson has recently isolated and crystallized this enzyme from active pancreatic extracts (Fig. 6). The enzyme

Fig. 6.
Carboxypolypeptidase.

is a globulin and may be recrystallized without change in activity or other properties. It acts in the presence of strong formaldehyde and differs in this respect from the other proteolytic enzymes of the pancreas.

EVIDENCE THAT THE ACTIVITY IS A PROPERTY OF THE PROTEIN MOLECULE.

Tests of purity.—The experiments just described show that crystalline proteins having intense proteolytic activity may be isolated from gastric or pancreatic extracts. It is an experimental fact that these preparations are crystalline proteins but it by no means follows directly that the enzymatic activity is a property of the protein molecule. If it could be shown that the preparations are pure substances it would, of course, follow that the activity must be due to the protein but it is unfortunately extremely difficult to prove the purity of proteins. The usual criterion of purity is constant composition and properties after repeated crystallization and these preparations fulfil that criterion. Solubility measurements furnish one of the most sensitive tests for mixtures and careful solubility measurements were done with crystalline pepsin. The results showed no evidence of more than one chemical compound. Diffusion experiments showed that the rate of diffusion of the active molecule was exactly the same as that of the protein, proving that the two molecules must be the same size at any rate, if not identical. If an inert protein, such as edestin, is stirred in a solution of pepsin the enzymatic activity is taken up by the foreign protein and at the same time an exactly equivalent amount of pepsin protein is taken up. Pepsin, trypsin and chymo-trypsin, under certain conditions, are transformed into denatured, insoluble proteins. At the same time there is a corresponding loss in activity. The denatured protein may be changed back to the native, soluble form and when this is done the activity returns. If the proteins are denatured by ultra-violet light there is also a corresponding loss in activity and the wave-length which is most efficient in denaturing the protein is also the most efficient one in destroying the activity (Gates).

Trypsin may be digested by pepsin and in this case again the loss in tryptic activity is just proportional to the amount of trypsin protein hydrolysed. The same experiment may be performed with chymo-trypsin and pepsin or with pepsin alone in strong acid solution. The foregoing experiments indicate strongly that these crystalline proteins possess enzymatic activity and the next problem is to determine what particular chemical structure in the protein is responsible for this remarkable property.

Acetylation of pepsin (Herriott) has furnished some evidence in this connection. A crystalline acetyl derivative was isolated which contains 3 or 4 acetyl groups attached to the primary amino groups (Fig. 7). This derivative has the same activity as the original pepsin. A second crystalline derivative containing 7 acetyl groups has also been isolated (Fig. 8). It has 60 per cent. of the activity of the original pepsin. The four additional acetyl groups which decrease the activity are probably attached to the hydroxyl group of tyrosine.

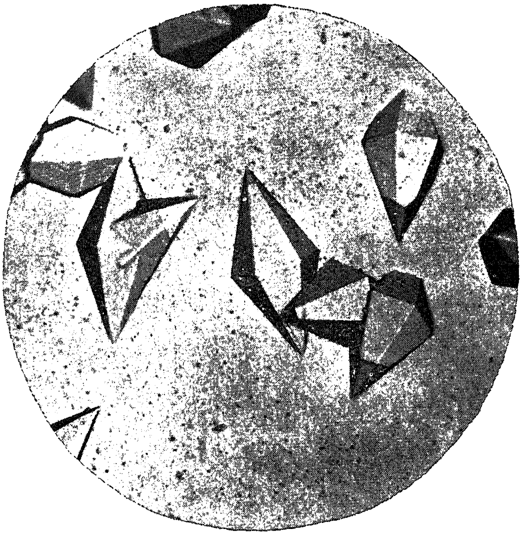

Fig. 7.
Four acetyl (100 per cent. active) pepsin.

Fig. 9.
Inhibitor-trypsin compound.

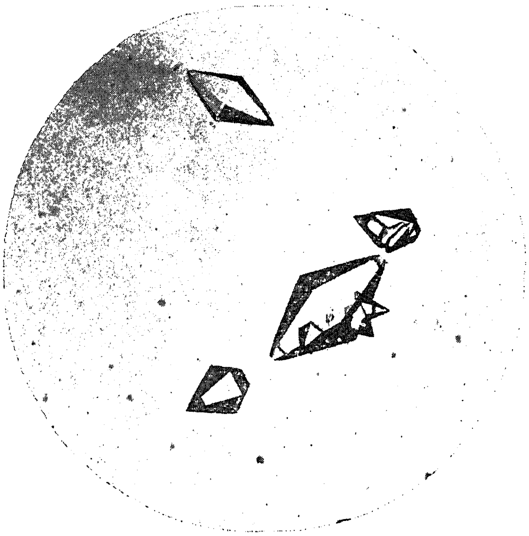

Fig. 8.
60 per cent. active acetyl pepsin.

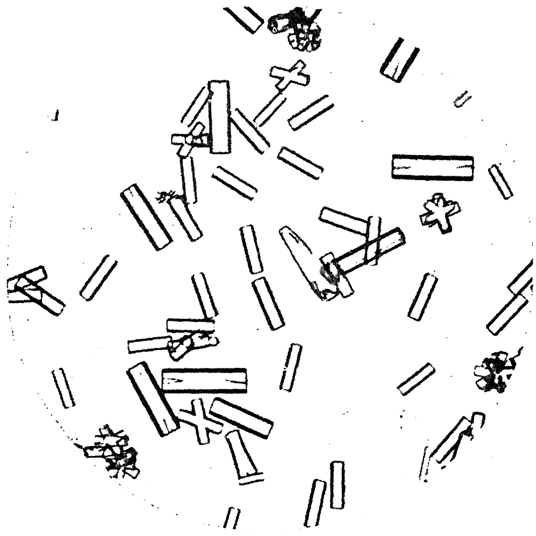

Fig. 10.
Inhibitor.

Evidently, therefore, the primary amino groups, which are presumably on the lycine, have no connection with the structure responsible for the activity, whereas the tyrosine is closely connected with the essential structure.

ACTIVATION OF TRYPSINOGEN.

Kühne and Heidenhain showed that fresh pancreatic juice has no proteolytic activity and only becomes active when mixed with a secretion of the small intestine. Vernon claimed that under certain conditions the activation was caused by trypsin itself, *i.e.*, the activation was autocatalytic, but this conclusion was denied by most subsequent workers. Isolation of the inactive form of trypsin has made possible a study of its activation. It has been found that in neutral solution the reaction is quite strictly autocatalytic, *i.e.*, the transformation of trypsinogen to trypsin is caused by the presence of trypsin itself. Trypsin, therefore, is an example of a molecule which may b

propagated since the inoculation of a solution of trypsinogen with trypsin gives rise to a very large quantity of trypsin and this process may be repeated indefinitely. In the crude extract this reaction is prevented by the presence of a substance which inhibits trypsin activity. A compound of this inhibitor and trypsin has been isolated and crystallized (Fig. 9). It may be separated into its constituents by treatment with trichloracetic acid. The trypsin precipitates and the inhibitor may be crystallized from the trichloracetic acid solution (Fig. 10). It has the general properties of a peptone and a molecular weight of about 6,000.[1]

[1] Summary of a paper presented before The Harvey Society, New York City, May 16, 1935.

Locust Research in Nigeria.

By F. D. Golding, M.A., F.R.E.S.
(*Agricultural Department, Ibadan, Nigeria.*)

INTRODUCTION.

BEFORE describing the locust research carried out by the entomological section of the Agricultural Department during the last five and a half years, it is necessary to give a brief account of the various species of locusts which occur in Nigeria.

Swarms of the Tropical Migratory Locust, *Locusta migratoria migratorioides*, R. and F., entered the south-western corner of Nigeria in December 1929, and had reached the Northern frontier by April 1930. Swarms have been present in this country ever since the original invasion and, each year, there have been two generations of hoppers.

In July 1930, hopper bands of the Red Locust, *Nomadacris septemfasciata*, Serv., were discovered near Lake Chad. Only one adult swarm has been found at a distance of more than about 12 miles from the lake.

Swarms of the Desert Locust, *Schistocerca gregaria*, Forsk., were present in that part of Nigeria lying to the north of the 12th parallel N. in April and May 1931; but, there is no evidence that *Schistocerca* either bred or caused damage to crops.

Occasional swarms of the Tree Locust, *Anacridium moestum melanorhodon*, Walk., have been reported from the north-western corner of Nigeria; but this species was not responsible for any damage to crops.

EXPLORATION OF SUSPECTED OUTBREAK CENTRES.

In June 1929, an elephant-hunter saw swarms of an unidentified species of locust migrating south-westwards to the central portion of the Nigerian shore of Lake Chad. These swarms settled and bred in this area. The presence of locusts in the Chad area some six months before the main invasion occurred led to Chad being regarded as a possible outbreak centre of *Locusta*. The discovery of numerous bands of *Nomadacris* hoppers in the southern half of Nigerian Chad in 1930 was the first record of the mass occurrence of the Red Locust in West Africa. As there was no evidence that swarms had migrated to Chad from the outbreak centre south of the equator it seemed probable that the bands were derived from solitary individuals locally.

In October and November, 1931, a preliminary survey was made of the shores of Nigerian Chad. It was found that *Nomadacris* was confined to the southern half of the shore and was associated with a tall grass, *Cymbopogon giganteus*, Chiov., which is absent from the northern part of the lake shore. *Locusta* adults of phases *solitaria* and *transiens* (*dissocians*) were found near the northern frontier and in the southern part of the shore. In June and July each year, *Locusta* swarms arrive from the south-west and breed in the Chad area, so it was impossible to say whether the solitary adults were derived from hoppers surviving the anti-hopper campaigns of 1930 and 1931 or, were the descendants of a permanent *solitaria* population. During the survey a site for a laboratory was selected at Kalkala near the south-western corner of the lake.

During the first six months of 1933 an ecological survey was made of the twelve square miles surrounding Kalkala. From January to April, the *Nomadacris* adults remained in *Cymbopogon* and other tall grasses. Shortly before the rains began in mid-May they commenced to spread from the tall grass areas into short grass and open farmland. Copulation was first

observed on June 20th. Phases *solitaria* and *transiens* (*dissocians*) of *Locusta* were present until mid-March though the number of individuals of both was small. From mid-March to the end of May only *solitaria* was present. Burning and grazing of the grass continually disturbed the locusts which were almost annihilated by Carmine Bee-eaters (*Merops nubicus nubicus*).

It was concluded that the Chad area is unlikely to be an outbreak centre of *Locusta* and that it was probable that conditions there are unsuitable for the production of the gregarious phase of *Nomadacris*.

The ecological survey at Kalkala was continued from September 1933, to January 1934, and from May to October 1934. In addition, a survey was made of a large section of the northern shore which had not been examined in 1931. As a result of this work it was concluded that the region from Kalkala eastwards to the French Cameroun frontier was probably merely the western fringe of a potential outbreak centre of *Nomadacris*. The Red Locust was found to absent from the northern half of British Chad and it was considered that conditions were unfavourable in that part of the southern shore lying to the north of Kalkala. Breeding began on June 1st, 1934, and oviposition was observed on the 16th of that month. As a result of a drought from mid-June to mid-July few hoppers emerged, and the Red Locust reverted to the solitary phase in the Chad area.

An interesting feature of this study was the discovery of *Nomadacris* adults in late October 1934, in areas some 30 miles to the south of the lake.

In May 1935, an entomologist was attached to a French locust mission and the southern shore of Chad was explored from the French Cameroun frontier eastwards to the south-east corner of the lake. Not a single specimen of *Nomadacris* was seen and the wooded character of this part of the shore makes it highly improbable that it is an outbreak centre of the Red Locust. At the conclusion of this work, a visit was paid to Kalkala and it was found that the solitary phase of *Nomadacris* has now become extremely rare in that district. It is possible that the energetic locust campaigns of 1930 and 1931, when about 20 Europeans were engaged in control work in the Chad area, prevented *Nomadacris* from attaining the swarming phase.

From April to September 1932, an entomologist explored the outbreak centre of *Locusta* in the Middle Niger region of French Soudan. The results of this work have not yet been published. The area was subsequently examined by a French locust mission.

FUTURE RESEARCH WORK.

In the near future it is proposed to examine certain marshes in the Bornu and Adamawa Provinces in order to determine the range of *Nomadacris* in Nigeria. It is possible that one or more of these marshes may prove to be a potential outbreak centre.

Every year it is proposed to visit the Chad area with the object of observing the *Nomadacris* population and of organising an anti-hopper campaign should there be any sign of transition from the solitary to the gregarious phase. After *Locusta* has reverted to the solitary phase, these annual visits will afford an opportunity of determining whether this species exists in the Chad area during the intervals between outbreaks.

THE EFFECT OF CLIMATE ON MIGRATION AND BREEDING.

Monthly maps showing the movements of *Locusta* swarms in Nigeria have been prepared since the beginning of the infestation in 1929. The swarm movements are studied in conjunction with climatic factors. As a result of such a study (for the first 17 months of the infestation) an entomologist concluded that with very few exceptions, swarms remain where the mean relative humidity (9 a.m., L.M.T.) is not more than 85% and not less than 40%. This worker also studied the effect of climate upon breeding and concluded that breeding does not commence after the dry season until the humidity rises to 65% and the degree of wetness (total monthly rainfall $\times$ number of days on which rain fell $\div$ 10) reaches 2.

A similar study is now being made of the data available for the first five years of the infestation.

Other branches of research are the biometrical study of adult locusts and the testing of various poisoned baits for use against hopper bands.

Quality in Foods.

By A. Sreenivasan, M.A.,
and
Dr. V. Subrahmanyan, D.Sc., F.I.C.
(Department of Biochemistry, Indian Institute of Science, Bangalore.)

IT has long been recognised that agricultural products can be characterised by certain properties which can be collectively described as quality. In some cases the quality can be defined in terms of certain physical characters such as size, shape, colour or behaviour on milling or cooking. In others, it depends largely on properties such as taste and flavour which are rather difficult to define but are, nevertheless, quite real. In recent years there has also been increasing realization of the importance of constituents such as, vitamins, proteins, calcium and phosphorus which are so essential to nutrition and, in consequence, are of great value in assessing the quality of food. As articles possessing the right quality are in great demand and fetch good prices, it is naturally of considerable interest, both to the producer and to the consumer, to determine the nature of the factors that determine quality and the conditions that favour its development.

The scientific study of the subject of quality was not taken up seriously until recent years. This was largely due to (*a*) want of adequate technique to measure the various subtle characters that make up quality, and (*b*) considerable amount of individual variations in regard to requirements of qualities such as taste and flavour. Progress in this line has, in consequence, been comparatively slow. Some useful results have, nevertheless, been obtained and the object of the present article is to make a brief survey of the more important findings and to indicate some of the more promising lines of future research.

Before taking up a discussion of the subject it may be useful to cite a few instances of quality in agricultural as well as horticultural crops. In the case of wheat, the milling quality is greatly valued. Recent enquiries (Bailey[1]) have shown that this is traceable not only to the variety of the grain but also to the nature of the soil on which the crop is grown and the manurial treatment which it receives. Thus, wheat grown on a heavy soil is generally 'stronger' than that raised on a light one. Likewise wheat grown in dry regions is 'stronger' than wheat grown in wet ones. High nitrogen content of the soil or application of nitrogenous fertilisers leads to increase in the nitrogen content of the grain and improved milling quality (Lawes and Gilbert,[2] Bailey, *loc. cit.*). Almost the reverse of the above is observed in the case of malting barley. Heavy soils may give good yields and even enrich the grain with nitrogen, but only the light soils yield grain of the desired quality—rich in carbohydrates but poor in regard to proteins. Application of nitrogenous fertilisers in more than moderate doses leads to diminution in quality (though the yield may increase) and consequent fall in prices.

In the case of tubers like potato and mangold-wurzel, heavy manuring leads to greatly enhanced yields but the quality of the produce suffers considerably. The tubers contain large amounts of water and partially assimilated salts, and, in consequence, possess (*a*) poorer keeping quality and (*b*) lower feeding value than those raised on similar, but unmanured or moderately manured areas.

Fruit crops generally do well on light soils, but the resulting quality is not so good as that obtained from heavy ones. Thus, a comparison of apples of the same variety grown on adjoining clay and light soil show that the fruits from the former are smaller and more green, but possess a greater proportion of sugar, acid and aroma than those from the latter. It is also the general experience of fruit growers that manures which act slowly but steadily (like farmyard manure) yield fruits of better taste and flavour than those receiving concentrated fertilisers which act rapidly.

It is a matter of common experience that market garden crops (such as cabbage), grown on mineral fertilisers, though developing to much bigger sizes, contain very much more water and perish more readily than those raised on unmanured or moderately manured soil. It has also been recently suggested that grain and fodder crops treated with organic manures are richer in regard to

vitamins and other growth-promoting factors than those receiving mineral fertilisers (Anon[3], McCarrison,[4, 5] Kottmeier,[6] Viswa Nath and Suryanarayana,[7] Breazale,[8] Krüger,[9, 10] Hunt,[11] Rowlands and Wilkinson,[12] Sirachenko[13] and Viswa Nath[14]).

The factors that contribute towards quality in beverages such as coffee, tea, cocoa, beer and wine, as also spirituous liquors such as brandy and whisky, have been the subjects of a number of researches in recent years. As the result of these enquiries, it is now recognised that, in addition to varietal differences, a number of external factors such as, altitude, soil conditions, manuring, period of rainfall, composition of the water used for brewing, the composition of the container—all contribute towards the collective impression of quality which is evaluated by the specialist taster. It is true that tasters are not infallible but it has, nevertheless, to be admitted that, in most cases, their judgment is not only reproducible by independent opinion but is also supported by popular favour.

Taste is made up of a number of components among which salinity, sweetness, sourness or pungency as the case may be, are no doubt the most dominant. There are also other subtle features to which the specialised human tongue is sensitive but which cannot be easily evaluated in terms of known chemical constituents. It is true that among the non-specialists, especially those indulging in excesses of certain kinds of foods, narcotics or beverages, tastes do not always agree and may even be quite opposed to one another. Thus it is known that one addicted to strong drinks, especially of the cheaper type, cannot make out the subtle distinctions in taste and flavour between the different brands of whisky or brandy; still less can he evaluate the lighter beverages which require an even more sensitive palate. On the other hand, the opinion of connoisseurs has invariably supported the evaluation of specialist tasters whose verdict determines, to a large extent, the prevailing market prices. It is necessary, therefore, that the producer should not only have further knowledge of the nature of the factors contributing to taste but also of the external conditions which determine them. By adequately controlling the latter, the taste of the produce can be improved with increased monetary returns to the producer.

Flavour is very much more difficult to define. It is generally associated with taste. The main constituents of flavour are often of the nature of volatile substances, but they do not contribute the entire effect. It is within the scope of the organic chemist, however, to identify the nature of the subtle constituents producing the desired effect, and, if necessary, even supply them in suitable proportions to substances lacking in them. It is also known that edaphic and other factors similar to those affecting taste also influence flavour, though to a different degree. It should be possible to define, more carefully, the nature of the relation between these factors, and even alter them, so as to obtain the desired flavour, which is often so highly prized.

In recent years, much valuable information relating to the quality of malting barley and its bearing on the brewing industry has been obtained. Thanks to the efforts of the Research Fund Committee of the Institute of Brewing, considerable progress has been made in devising and perfecting laboratory technique, and there is every prospect of it soon being possible to replace experimental maltings by rapid laboratory analyses.[15] The importance of the nitrogen content of the cereals in the brewing industry has been recognised more or less clearly ever since scientific methods were first applied (Munro and Beaven,[16] Beaven[17]). It is known that the nitrogen compounds act as dilutents of the carbohydrates of the grain and hence reduce the available extract; they also serve as essential aliments for the micro-organisms concerned and govern, to some extent, the enzymic activity; further, high nitrogen in

barley leads to malting loss by both increased respiration and rootlet growth and also to difficulty in modification. Quality in beer depends on several factors like flavour, colour and aroma and is in the main determined by conditions of malting, hopping and fermentation. The majority of recent investigators agree that head retention, palatefulness and both colloidal and biological stability are largely dependent on nitrogenous substances derived from the original protein constituents of the barley. The maltster prefers low nitrogen barleys because they modify more readily and have a lower "malting loss", whilst the brewer knows that they give higher extracts, and, he believes, bright and relatively stable beers. The effect of these preferences has been shown by the high valuations generally placed on low-nitrogen barleys in the market. On the other hand, it has been suggested that such barley may be deficient in enzymic activity, yeast feeding material and those nitrogenous substances which are mainly responsible for palate fulness and head retention (Cluss[18], Stadler[19]). Bishop's work[20] would suggest, however, that, within one variety, the total quantity of nitrogen in barley and its quality may not be so unrelated as has been supposed by some. It is already possible to connect, quantitatively, certain factors in the brewing value of barley with nitrogen content. From a statistical analysis of some of the results obtained for barleys and malts in the course of his research, Bishop[21, 22] has derived a formula which may be used to predict the yield of extract which should be obtainable from any given sample of barley, when malted under normal conditions. This formula is based on a knowledge of the nitrogen content, moisture and thousand-corn weight of the barley. Chemical analyses are thus assuming a fundamental significance and already workers (Bishop,[23] Steven,[24] Russell and Bishop, *loc. cit.*) are studying the cultural conditions on which the various factors depend.

Breadmaking is one of the most ancient of industries, but scientific control of the various processes is not yet a feature of standardised procedure. Mass production of such an article as bread, demanding close attention to temperature, fermentation conditions and time factors, as well as a recognised standard of public taste, necessitates an intimate knowledge of "what happens". At the Symposium on Bread and Milk held in 1933 under the auspices of the Food Group of the Society of Chemical Industry, there were presented a number of communications (Jørgensen,[25] Brabender,[26] Eyre,[27] Jago[28] and Kent-Jones[29]) which related to the control of wheat so as to produce the best flour and of flour so as to produce the best bread and the forecasting of the value of flour in practice by laboratory tests. It is of course realised that wheats grown in different parts of the world yield flours of very different baking qualities. The development of elastic properties and of distensibility in dough during leavening are the most important quality factors of flour. Bakers naturally prefer what is popularly designated "strong" flour. This strength is rather difficult to define, but it may be stated that it is a condition which facilitates the making of bold, upstanding loaves of good texture. The demand for strong wheat cannot always be easily met. Fortunately, it was found that flour improved in strength and baking quality if it was stored for some time. Later on, it was found that minute quantities of certain chemicals (such as one part of persulphate in 15,000 to 20,000 of flour) produced effects as good as, if not better than, those given by long storage. The most widely used "improvers" at present are ammonium persulphate, potassium bromate or mixtures of chlorine and nitrogen trichloride. It is generally believed, however, that such treatments destroy flavour and that the craze for increased yield per acre has resulted in wheats of poor flavour.

The Food Group Symposium (*loc. cit.*) was also productive of valuable contributions (Kay,[30] Wilson,[31] Drummond[32] and Minett and Pullinger[33]) surveying the improvements

which have been made in milk supply of recent years, and pointing out how very desirable it is that quality of milk should be raised, even at the expense of quantity, by systematic breeding. The development of "off" flavours and other defects in butter has long exercised the minds, not only of the traders, but also of scientific workers. In this connection, the effect of wrapping materials, alleged to be the cause of taints and of the development of tallowy flavour, as also the nature of the factors causing auto-oxidation of the fats, are being investigated (Davies[34]).

The cooking qualities of different specimens of *dhal* (red gram or pigeon pea, *Cajanus indicus*) vary considerably, some requiring long continued boiling to reach the desired stage, whilst others cook quickly and the object of the purchaser is naturally to acquire the latter type. Apart from the cooking qualities, it is generally found that the quality of the water used for boiling has a considerable effect upon the rate of cooking. Indeed, as has been shown by Viswa Nath *et al.*,[35] the rate of cooking depends upon two factors, namely, the amount and the kind of dissolved substances present. With neutral salts, the effect is a general retardation, whereas in the case of alkaline salts, the rate of cooking is accelerated; in either case, the effect increases with the salt concentration.

"Bloom" in meat is described as the "freshly killed appearance of the meat" and its preservation is a matter of considerable interest to the producer. The problem of ascertaining how far the conditions of freezing, storage and transport of mutton can be modified so as to improve its "bloom" and general quality has merited close co-operative investigation.[36] Loss of bloom can be closely connected with loss of water by evaporation or by sweating. To diminish loss by evaporation, it is recommended that the carcasses should be enclosed as quickly as possible in bags impermeable to water vapour.

Toughness in meat is another serious problem which has not yet been satisfactorily solved. It is known that, in many cases, prolonged exposure to atmospheric conditions helps to soften the meat and to render it fit for cooking. There are others however which continue indefinitely to be tough and thus prove to be a source of considerable annoyance to the consumers. This defect can be largely overcome by treatment with small quantities of digestive ferments such as papain. Further work is needed however to standardise the conditions in such a manner that every housewife can easily adopt it.

Growers of fruits and vegetables have been confronted with the problem of maintaining a high quality in their produce, of preventing their turning brown or developing unpleasant odour on storage and of reducing their susceptibility to fungal invasion and decay. The National Institute of Agricultural Botany at Cambridge has been doing useful work in estimating the quality of already established varieties of potatoes. The main requirements of the potatoes are that the flesh shall be white, that a minimum amount of discolouration shall be produced when they are boiled or steamed and then reheated. A floury texture is demanded by a vast majority of consumers. It is also important that the potato should have shallow eyes so that it can be peeled easily and without waste. It must also survive storage for long periods and stand transport without damage. When chipped, the outer surface should be crisp and of a rich golden brown colour, while, internally, there should be a layer soft in consistency. In addition, it is generally considered an important point that as little fat as possible should be absorbed in the process of frying. As a result of a large number of trials with tubers cooked under standard conditions, the Institute has been able to show that there is exceedingly little variation in the results of tests carried out at different times; that the same variety grown in different localities shows greater divergences in quality than different varieties raised in the same place; that colour after cooking and, to some extent, consistency of flesh are influenced by soil rather than by season and other factors (Parker[37]). Standard laboratory tests to measure the presence of certain qualities in the potato have also been devised. Thus, Tinkler[38] has recently published a method for determining, chemically, the susceptibility of potatoes to blackening

on cooking, while Peacock and Brunstetter[39] have devised a chemical method of determining their suitability for chipping.

Rice is the staple food of hundreds of millions in India and in the East in general. Indeed, among the foods of men, it holds the foremost place, the estimated normal yield being 440 billion pounds of rough rice against 276 billion pounds of the second crop, wheat. More than 35 per cent. of the total cultivated area of India is under rice. There are several thousands of varieties recorded. In addition to this, a large number of new varieties are being added every year as a result of hybridisation between existing varieties.

The ultimate purpose of improvement in rice culture is to obtain grain with good hereditary qualities. Some varieties recommend themselves by high yield, others by good milling properties, keeping quality, fine taste, pleasing appearance, fitness to a variety of soil conditions, resistance to adverse weather conditions, pests and diseases, ease of harvesting and in various other ways. A thorough knowledge of the variations in the different items of qualities in rice is very essential, so that, armed with this knowledge, the breeder can attempt to combine high yields with superior quality.

The yield of head rice comprising the whole kernels is an important item both for the growers and the millers. The factors which contribute to high milling quality in rice are yet ill-defined, though it has been the experience of farmers that great care is needed to stop irrigating in due time and proceed promptly with the harvest. The prominence or otherwise of ridges on the rice kernel, formed as a result of the kernel growing against its case, the hull, would also appear to determine the milling quality of the rice. The less prominent these ribs are, the more suitable the grain is for milling.

From the point of view of the market value of the grain, there is another important quality in rice which finds expression in the appearance and texture of the grain. In common rice, a large part is vitreous (corneous) composed very largely of starch, but it contains also an appreciable amount of albuminoid substance. The more completely vitreous, the harder as a rule is the kernel, and the better the quality as this is usually judged. A part of the endosperm—a very small part in the best commercial rices—is white, opaque and chalky in texture. This part of the endosperm is relatively weak in albuminoids. The corneous rices include the best commercial varieties; they keep and stand shipment better than the usually softer, opaque rices. What is called glutinous rice has uniformly chalky and not very hard kernels. In glutinous rice, the endosperm contains considerable percentage of soluble starch and dextrin besides some maltose. Such rice is sometimes called dextrinous in distinction to starchy. It is called glutinous because it forms a sticky mass when cooked; but no substance which ought to be called gluten is responsible for this behaviour (Tanake,[40] Kikkawa[41]). Glutinous rice is hardly known in many parts of India, but it is greatly favoured in Japan and China. About 8 per cent. of the rice area of Japan is planted with such varieties and in China the estimate is as high as 20–30 per cent. They are largely used for making pastries. It would be of considerable scientific as well as practical interest to determine the nature of the relation between hard, soft and glutinous varieties of rice and to assess their relative nutritive values.

In the commoner varieties of paddy the period lapsing between the germination of the seed and the harvesting of the grain varies from about three to eight months. The ryot chooses the short period crop in anticipation of either (*a*) irrigation facilities for two or more crops in a season or (*b*) unfavourable climatic conditions which might destroy a long-standing crop. It is generally believed that short duration varieties are poorer in quality than long duration ones, because they are assumed to remove less of plant food from the soil. Thus, in South India, short duration *Kuruvai* or *Kar* varieties are not valued so much for their nutritive qualities as the long duration *Samba* varieties. Similarly in Bengal, it is held that *Aus* rice is inferior to *Aman* practically in all respects. Chemical analyses also show that *Aman* varieties are generally richer in protein, fat and potash contents than the *Aus* varieties (Basu and Sarkar[42]). If this belief were true, it would follow that although the farmer loses in total yield by

[39] Peacock, W. M., and Brunstetter, B. C., *U. S. Dept. Agric. Circ.*, 1931, 158.

[42] Basu, K. P., and Sarkar, S. N., *Ind. Jour. Med. Res.*, 1935, **22**, 745.

raising a long period crop, he gains considerably in quality. Scientific evidence to warrant the popular belief that short duration crops are deficient in nutritive constituents is still lacking.

Although in rice-growing lands, the general preference is everywhere for white rice, there are still a great number of recognised varieties of coloured rices deliberately grown, because of distinctive flavour, high yield, or the belief that they are especially nutritious. It is also stated that red rice is generally rich in iron and phosphorus. These have to be verified. The presence of red in the milled rice being itself evidence of incomplete milling, this incompleteness may explain the nutritive value of such rice.

Rice is essentially a water crop. Practically all the rice of commerce is irrigated, as is also by far the larger part of rice locally consumed by all the rice-producing countries. Irrigated rice is, in general, the more productive also. Even those varieties of rices which are cultivated dry are more productive if irrigated. McCarrison[42,43] has adduced evidence to show that the wet crop is poorer in nutritive value than the dry one. If this is found to be generally the case, it would be desirable to extend the method of dry cultivation and, if possible, improve on it so as to combine superior quality with high yield. In this connection, it may be mentioned that silicate fertilisation has been found by the authors to improve the yield of rice under dry-land conditions.

It is well known that rice prepared by husking recently harvested paddy (*a*) cooks rapidly to a shapeless paste and (*b*) causes digestive disorders on being taken. After storage for some time, however, the same rice cooks properly and is easily digested. Apart from the difficulty in husking fresh paddy without breakage, the quantity of cooked rice is very much less in the case of fresh grain than in that stored for some time. The question of storage and its effect on the nutritive value of rice requires investigation. The nature of the chemical changes taking place during storage, as also the significance of such changes in relation to the nutritive value of rice prepared out of them, would require careful scientific study. In practice, some varieties are stored for longer periods than others. Short duration crops generally require longer storage than long duration ones. A systematic study of the conditions relating to the above as also the comparative efficiencies of different methods (Srinivasan[44]) now in vogue would be of much practical interest.

In most rice-growing countries, a part of the annual output of grain—some varieties to a greater extent than others—is subjected to parboiling prior to milling. The paddy is cleaned, then soaked in water for a definite time and afterwards steamed till the outercoats just begin to burst. The conditions relating to parboiling are highly variable (Srinivasan, *loc. cit.*, p. 59), but, irrespective of this, parboiled rice is generally considered to be more nutritious than raw rice; when cooked, it keeps well for considerable lengths of time, either by itself or soaked under water. Besides, it is claimed to possess greater sustaining power than raw rice. Such rice also mills better (Ishaq[45]). Following the observations of Braddon,[46] Fletcher,[47,48] Ellis[49] and others who observed that people who eat parboiled ("cured") rice generally escape beriberi, several workers (Fraser and Stanton,[50-52] McCarrison and Norris[53]) have investigated the antineuritic value of raw and parboiled rices and shown that samples of parboiled rice, even when milled, protected pigeons from polyneuritis whereas raw polished rice caused the disease. Recently, Aykroyd[54] has shown that parboiled rice contains more vitamin B_1 and has a greater phosphate content than raw rice milled to the same extent. He has made the suggestion that the better nutritive value of parboiled rice is due to diffusion of the vitamin B_1 from the outer layers into the inner endosperm during the parboiling process. McCarrison[55] has, however, shown that vitamin A which is present in raw paddy or rice

is destroyed in great part during the parboiling of paddy and that pigeons fed exclusively on parboiled rice develop symptoms of ophthalmia. McCarrison and Norris (*loc. cit.*), while confirming the above observation, have further shown that the boiling and steaming of paddy (parboiling) with subsequent sun-drying reduces its nutritive value, and that it is related to loss of vitamins A and B consequent on the action of heat and oxidation. It would appear from the above that the influence of parboiling on the vitamin content of the grains has to be more thoroughly investigated and conditions determined for their maximum conservation. No scientific study on the effect of parboiling on the chemical composition and the nutritive value of rice or on the biochemical changes undergone by the grain during the process of parboiling has also been carried out. It may be mentioned that recent observations in these laboratories have shown that parboiled, milled rice is richer in nitrogen, phosphorus and minerals in general than raw rice milled to the same extent.

At one time, rice of commerce was entirely hand-pounded. The product thus obtained was always slightly coloured and was associated with a small quantity of bran. With the advent of machinery, however, human labour (with its desirable imperfections) was steadily eliminated until to-day we find that not only exported rice but also a very large part of the grain used for home consumption is entirely mill-pounded and polished. The polishing is generally carried to such an extent that the bran layer is almost entirely removed. It is now being increasingly realised, however, that polished rice is devoid of vitamin B_1 and other essential growth promoting factors which are lost with the bran. It would be desirable, therefore, to adopt some system of pre-treating rice which would reduce losses through polishing to a minimum; to combine the pleasing appearance and the keeping quality of polished rice with the superior nutritive value of unpolished rice. It has been found that parboiling under certain standard conditions achieves this end and if this is confirmed by further experiments, such a procedure would deserve to be extensively adopted. Carefully prepared parboiled rice mills better than raw rice and keeps well. On polishing, its colour improves considerably. The finished product cooks nearly as white as raw rice.

The foregoing are but a few instances to show the importance of a systematic investigation on quality in crops. Detailed study of some of the problems mentioned above would not only throw light on the nature of physiological response of plants to a variety of conditions, but also help considerably to modify our present system of agriculture so as to combine quality with quantity. Scientific study of quality in crops is yet a virgin field of research and one from which far-reaching practical results might well be forthcoming. It is pleasing to note that some of the problems referred to in the course of this review are already under investigation at some of the research stations in this country. Particular mention may be made of the researches on quality in tea and coffee at Tocklai, Devarshola, Balehonnur, Bangalore and elsewhere; studies on rice at Dacca, Bombay, Coimbatore, Bangalore and at other stations; enquiries on the nutritive value of various foodstuffs at Coonoor, Bombay, Bangalore and a few other centres. Much more yet remains to be done and it is hoped that, in the years to come, it may be possible to combine high yields with superior quality, thus providing the consumers with cheaper and, at the same time, better acceptable and more wholesome food than in the past.

Quinochromes.

THE oxidation of the non-fluorescent Vitamin B_1 by permanganate and manganese oxides at pH 6-7, is accompanied by the production of a blue fluorescent substance, which is yellow in acids. Sulphur is not split off as sulphate but the state of combination of S changes. This product shows biological activity even though it does not give the formaldehyde-azo colour reaction for Vitamin B_1, which indicates that more than one Vitamin B_1 exists. The properties of the blue substance are discussed in an important paper by Kinnersley and collaborators (*Biochemical Journal*, 1935, **29**, 2369-2384). The authors are led to the conclusion that the view that Vitamin B_1 might be thiophyramidazine (hexahydrothiolumichrome) is no longer tenable. Vitamin B_1 appears to be pyramidine thiazole. It is probable that both the biological activity and the colour reaction are connected with the $-NH_2$ group at 6, which would therefore be capable of existing in two states of oxidation $-NH_2$ and $=NH$.

Permo-Carboniferous Life Provinces, with Special Reference to India.

By B. Sahni, SC.D. (Cantab.)
(*Professor of Botany, University of Lucknow.*)

AT the recent meeting in Amsterdam (Sept. 2–7, 1935) of the Sixth International Botanical Congress, the inter-relations of the Late Palæozoic floras were discussed by various geologists and palæobotanists. After Professor T. G. Halle's Presidential Address to the Palæobotanical Section, Professor A. C. Seward, F.R.S., opened the discussion with remarks on the "Nature and significance of geobotanical provinces". He dealt, *inter alia*, with the difficulties attending a decipherment of the records of the rocks, particularly those connected with the climatic implications of extinct forms of plant life. Perhaps the most striking observation in this masterly discourse, characteristic of a man of Professor Seward's authority and experience, was that today he knew less about the value of fossil plants as tests of climate than he did forty-three years ago, when he wrote his well-known Sedgwick Prize Essay for the year 1892. Among others who followed with papers on various aspects of the problem, was Professor Halle himself, who discussed the relation between the Late Palæozoic floras of Eastern and Northern Asia (pp. 227–228).[1] Professor R. Kräusel of Frankfurt a.M. spoke on the distribution of the Devonian flora. Professor W. Gothan of Berlin dealt in two papers with the inter-relations of the Permo-Carboniferous life provinces (pp. 226; 242–244). Professor W. J. Jongmans of Heerlen discussed the distribution of synchronous floras with special reference to the movement of the poles and of continental blocks (pp. 239–242). Professor A. Renier of Brussels offered remarks on stratigraphical correlations in and between the geobotanical provinces (pp. 244–245). Lastly, the present writer read a paper on the *Glossopteris* flora of India and its phytogeographical relations (pp. 245–247), of which a summary is given below.

Immediately after the Amsterdam Congress, an international gathering of about eighty geologists and palæontologists met in Heerlen (Sept. 9–12) for the Second Congress of Carboniferous Stratigraphy under the auspices of the Geologisch Bureau of the Nederlands. Here we had the advantage of the presence of the veteran geologist Dr. W. A. J. M. van Waterschoot van der Gracht, Mr. D. N. Wadia of the Indian Geological Survey and other geologists interested in tectonic problems connected with Asia. Among many interesting and important items on the programme, Professors Jongmans and Halle presented their Amsterdam papers again under these new auspices, and in this connection the writer also had the privilege of discussing that part of his paper which dealt with the relations of the Indian Gondwana flora with those of Siberia and China.

As the space allotted for the advance abstracts of the Amsterdam Congress was necessarily limited, and as the full paper will be delayed in publication, I propose to give below an extended summary in the hope that it may be of interest to readers of *Current Science.* The full paper will appear in the *Proceedings of the Indian Academy of Sciences* for 1936.

It is generally agreed that towards the end of the Palæozoic era there existed four more or less well-defined botanical provinces. In the southern hemisphere there was the Gondwana continent, with its very characteristic *Glossopteris* flora. This flora also extended into India, which now lies north of the Equator. Gondwanaland was separated by a great Mediterranean Ocean, the Tethys, from the other three provinces which had more or less distinct floras of their own. These were, *firstly*, the Arcto-Carboniferous province, inhabiting the area now occupied by parts of Europe and eastern North America; *secondly*, the province of the *Gigantopteris* flora, developed in parts of western North America and in China, but extending south into Sumatra; *thirdly*, the Angara province, stretching eastwards from near the Ural Mountains as far as the Pacific Coast, and southwards as far as the Tarbagatai Range, within a few degrees north of Kashmir. The floras of these three northern provinces have more in common with each other than any one of them has with the Gondwana flora. Their geographical relations are best understood by viewing the globe from the Arctic pole (Fig. 1).

[1] These page references are to the *Proc. 6th Internat. Bot. Congr.* (Sec. PB), Amsterdam, 1935, Vol. II.

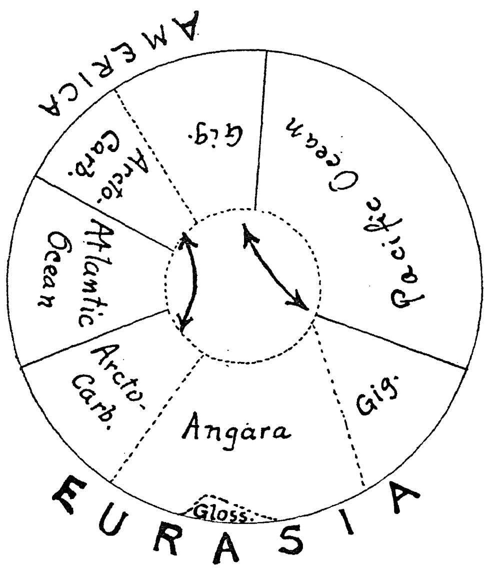

Fig. 1.

It is noteworthy that both the Arcto-Carboniferous province and the *Gigantopteris* province are cleft longitudinally into two blocks each, the blocks of each pair being separated by wide oceans, the Atlantic in the one case, the Pacific in the other. But towards the pole the two halves of each province tend to approach each other, although their actual meeting has not yet been proved. In Eurasia, the Angara flora is wedged in between the other two floras. In its affinities, so far as they are understood at present, the Angara flora is perhaps the most interesting of all, because it contains elements of all the other three floras in addition to a large proportion of genera and species peculiar to itself. The synthetic nature of the Angara flora is perhaps best understood if we look at the globe from, say, the Altai Range: Angara Land is then seen to occupy a central position, as one amongst the four life provinces. Lastly, the *Glossopteris* flora, although containing stray elements of the "northern" type, is for the most part a distinct assemblage, strongly characteristic of the southern hemisphere. This province is perhaps best seen from the southern pole, although from there India goes out of the view.

The present relative positions of these four life provinces raise palæogeographical problems which have led to much speculation. If, as seems probable, these floras were largely contemporaneous, it is difficult to imagine that two floras so distinct from each other as, for example, those of India and Sino-Sumatra should have evolved and flourished side by side, where we now find them on the map: almost cheek by jowl and crossing much the same latitudes. On the other hand, there is the equally puzzling anomaly that countries with closely related floras lie on the opposite sides of the biggest oceans of the globe: China and western North America; eastern North America and Europe; India and the southern continental blocks. But these are only a few of the problems with which the whole subject bristles. The satisfactory solution of all these problems is a thing of the distant future; but that future has been brought somewhat nearer by the recent work in Central and Eastern Asia of Swedish, American and Chinese investigators, and elsewhere by a host of workers on different aspects of the subject.

In the following necessarily condensed account, I shall first record my conclusions regarding the geological range of the Indian *Glossopteris* flora and the climatic conditions in which it was probably evolved, and then pass on to a brief discussion of its relation with the contemporary floras of Siberia and China.

THE *Glossopteris* FLORA OF INDIA AND ITS PHYTOGEOGRAPHICAL RELATIONS.

1. In India the *Glossopteris* flora probably ranged from the Upper Carboniferous to the Trias. The lower limit is indicated by the relations of the Talchir glacial beds and the earliest plant-bearing Gondwanas with marine fossiliferous horizons of determinable age, particularly in Kashmir and in the Salt Range.

Beginning in all probability as a meagre cold temperate flora in the latter part of the Talchir (Upper Carboniferous) period, it rapidly became richer as the climate became warmer (Damuda = Permian). In the Panchet stage (Lower Trias) stray elements of the then widespread *Dicroidium* (*Thinnfeldia*) flora became mingled with a still dominant *Glossopteris* flora. In the Parsora stage the *Dicroidium* element seems to have predominated over a waning *Glossopteris* flora. *Glossopteris* itself has not been recorded from Parsora itself but *Nœggerathiopsis Hislopi* and other characteristic Lower Gondwana plants co-existed with several species of *Dicroidium*, which abounded. The Parsora beds cannot possibly be of Jurassic (Upper

Gondwana) age, as C.S. Fox[2] believes: they clearly belong to the Permo-Triassic part of the Lower Gondwanas and may be even as old as the Upper Permian, as Professor Seward has suggested.[3]

2. The meagre evidence available supports the current idea that the main part of the *Glossopteris* flora was developed in a temperate climate. There is certainly no evidence that it was in any sense a glacial flora, although in sheltered spots early members of the flora may well have co-existed with the retreating ice. Nor is there any clear evidence of tropical conditions such as are believed to have existed in the Arcto-Carboniferous province.

3. The only other Carboniferous flora known in India is the geographically important Himalayan outpost of the *Rhacopteris* flora in Spiti (Thabo stage of the Po Series) which, as Gothan has suggested, is probably of Lower Carboniferous age, not Middle Carboniferous as formerly believed.

4. In several parts of Gondwana Land, particularly in South America and South Africa, species related to or identical with members of the European flora have been found associated with the indigenous southern flora. These so-called "northern" elements have generally been regarded as immigrants, but I am inclined to interpret them as remnants or descendants of the pre-existing southern flora. They occur chiefly in the earlier Gondwanas and have been compared or identified with European Upper Carboniferous or Lower Permian forms. Some of the lycopods are comparable with pre-Gondwana southern types. They may have persisted through the glacial period in regions relatively free from the rigours of the ice.[4]

5. The relations of the Indian *Glossopteris* flora with the Palæozoic flora of Angara Land are still very imperfectly known. The Angara flora, of which our modern knowledge is based chiefly upon the works of Professor Zalessky and of Miss Neuburg, contains (i) a large indigenous element, peculiar to Angara Land, (ii) a very considerable Arcto-Carboniferous element, (iii) a small but important *Gigantopteris* element, quite recently discovered, and (iv) a large number of forms more or less resembling, and a few perhaps identical with, plants characteristic of Gondwana Land. Although the Gondwana affinities may have been somewhat over-emphasised in the past, as Halle and others have suggested, there seems no doubt that the two floras were not evolved independently: some means of intermigration must have existed. Whether this was by a direct route, through Kashmir, as suggested by the writer in 1926, or by an indirect route, possibly through China, is an open question. Meanwhile, a critical comparison of typical specimens of the two floras is urgently needed; a comparison of the faunas should also be helpful. The Lower Gondwana flora of northern India, particularly that of Kashmir and the Salt Range, should be further explored; and any acquisitions of plant-fossils from the ancient coast-line of Gondwana Land, which lay along the southern margin of what is now the Himalayan chain and on the east from Assam to Burma, should be closely examined. Investigations in the intervening region between northern India and the Altai range may possibly bridge the already narrow gap between Kashmir and the southernmost Angara localities in the Tarbagatai. In that case, as tentatively suggested in 1926 (*loc. cit.*, p. 241) the Kashmir flora may be only a southern outpost of the Angara flora.

But, on the other hand, it may after all turn out that the suggested affinity of the still meagrely known Kashmir flora with that of Angara Land was only apparent, or less close than imagined. Certain geological considerations would seem, indeed, to preclude any means of terrestrial migration from Kashmir to Siberia during the late Palæozoic. D. N. Wadia's important work in N.-W. Kashmir and Hazara[5] seems to have established that the chain of the Himalayas, representing the uplifted and folded marine sediments of the Tethys, is structurally continuous round the great re-entrant angle in our northern mountain barrier. Unless further investigations reveal evidence of a break in the marine zone, either here or further to the west or east, the marine barrier between India and Siberia must have been a truly formidable one: it is now represented, as Dr. van der Gracht

[2] Fox, C. S., "The Gondwana System and related formations," *Mem. Geol. Surv. Ind.*, 1931, **58**, 189-190.

[3] Seward, A. C., "Fossil Plants from the Parsora Stage, Rewah," *Rec. Geol. Surv. Ind.*, 1932, **66**, (ii), 242.

[4] Sahni, B., "The Southern fossil floras, a study in the plant-geography of the past," *Proc. 13th Ind. Sci. Congr.*, Pres. Addr. to Geol. Sec., Bombay Meeting, Jan. **1926**, **p. 241**.

[5] Wadia, D. N., "The syntaxis of the N.-W. Himalayas", *Rec. Geol. Surv. Ind.*, 1931, **65**, (ii), 189-220.

emphasised at Heerlen, by some of the highest mountain ranges in the world, including the Himalayas and the Karakorum. In the face of these considerations, Zalessky's hypothesis of a connecting isthmus or a chain of islands across the Tethys does seem bold, but then the Gondwana resemblances of the Angara flora, which, I believe, are undeniable though they may have been exaggerated, must be explained by an indirect route, still to be discovered. This is a point on which investigations not only in China and Central Asia but also along the old Gondwana coast-line in the Nepal-Assam-Burma region may be expected to throw light.

6. Further east across the Tethys, in China, there flourished a vegetation which had much more affinity with that of the Euramerican continent, and some affinity even with that of Angara Land. With the Gondwana flora there was much less in common. But although essentially a northern flora, the *Gigantopteris* flora crossed the equator into Central Sumatra[6] where it appears to have pushed itself like a wedge into the Gondwana province. I believe that this peculiar dovetailing of the sharply contrasted northern and southern floras can only be explained on the view that originally the two provinces were far separated by the ocean (Fig. 2), but have since been brought into contact by a horizontal drift of one or (as I consider much more probable) both land areas (Fig. 3). The old Gondwana promontory of N.-E. Assam may be regarded as a pivot round which the Burmo-Chinese mass, formerly situated much further to the north, moved southwards and westwards, along the arc of a circle.

How far this suggested syntaxial bend round N.-E. Assam, compared with that which Mr. Wadia has so ably demonstrated in the N.-W. Himalayas, is supported by structural geological evidence, is for the future to show. The idea was suggested to me by purely palæobotanical considerations but, as I learned subsequently, several geologists have previously expressed the belief that the chain of the Himalayas is continued southwards round Assam into Burma and the Malayan arc of islands. The alternative view of Kingdon Ward that the Himalayas continue eastwards through China, as far as the Pacific Coast, seems quite untenable, as the region of China where his supposed eastward continuation would lie was a land area inhabited by the *Gigantopteris* flora.

It may be that the present region of Sumatra formed a *southward* promontory of the northern continent, round which the sediments of the intervening geosyncline, lying to the north of the Indo-Australian mass, became folded and bent into an angle or arc, in much the same way as round the Kashmir and Assam promontories. But the position in this region seems much more complicated, and in any case the subject is beyond our present scope. The main point one may venture to suggest is that palæobotanical explorations in the Malayan

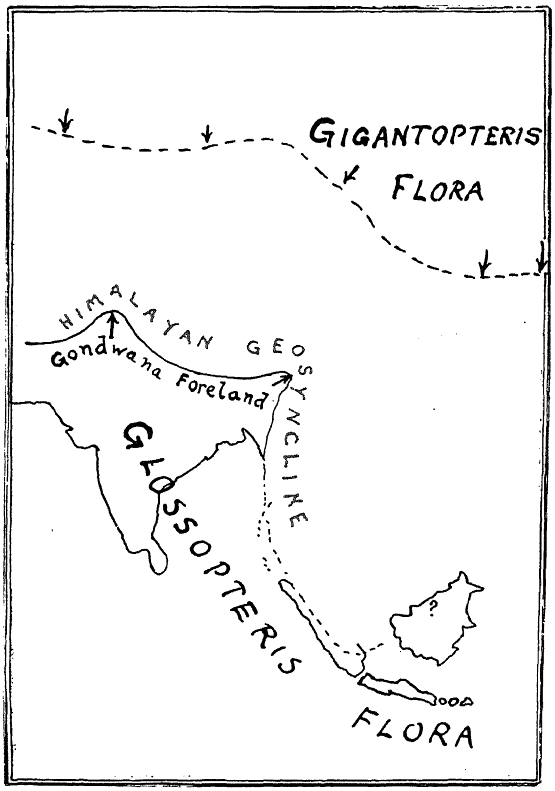

Fig. 2.

arc and further to the east should probably establish the eastward or north-eastward continuation of the tectonic boundary between Gondwana Land and the *Gigantopteris* province.

Wet., Amsterdam*, 1927, **30**, (6); Jongmans and Gothan, (1935) "Die palæobotanische Ergebnisse d. Djambi-Expedition," *Jaarb. Mijnw. in Nederl-Ind.*, 1930, "Verhandelingen".

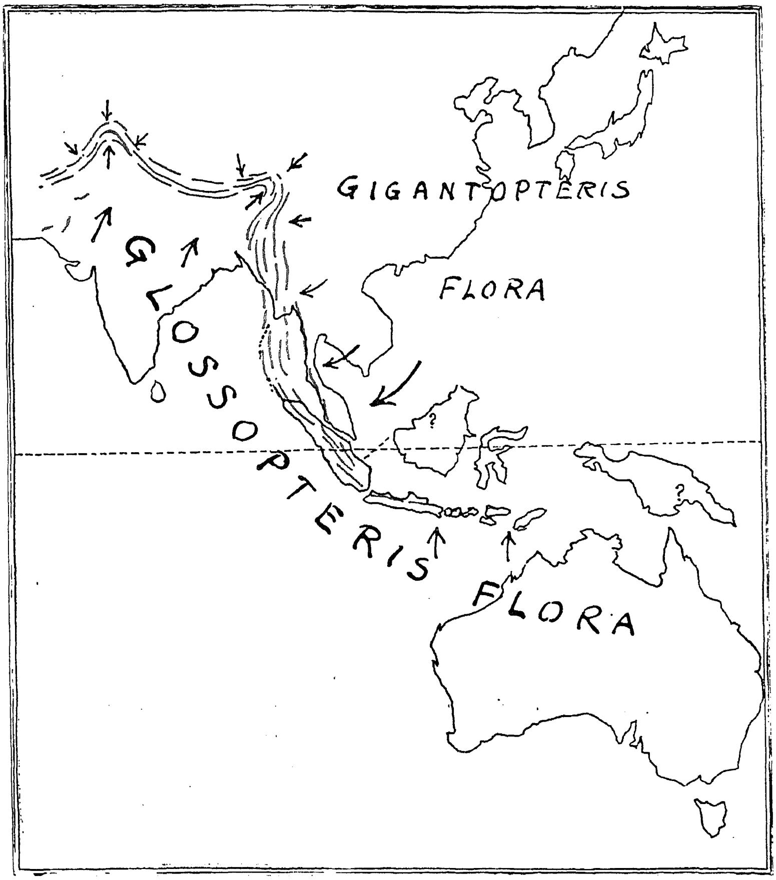

Fig. 3.

It remains to add that while the above ideas were arrived at independently I owe the original impetus for them to certain suggestive remarks made by Professor Halle, in his classical memoir on the Shansi flora,[7] where he drew attention to the close proximity of the Indian and Chinese floras and hinted that this anomalous position may have had something to do with the tectonic features of the intervening region. The above hypothesis would also explain the apparent anomaly of two climatically distinct floras lying, as they now do, athwart the same latitudes. There need not, therefore, be any serious difficulty, at least on geographical grounds, in accepting the idea that while the "Arcto-Carboniferous" flora (including its Sino-Sumatran phase) was developed in a relatively warm and humid climate, the *Glossopteris* flora was essentially a temperate flora.

In reply to an enquiry my esteemed friend Mr. Wadia also wrote to me that he thought a N.-E. tongue of the Indian horst had much to do with the acute southward bend of the Assam mountains into Burma. To him and to Dr. F. R. Cowper Reed, I am indebted for references to geological literature on this aspect, which showed that the problem has already received attention from many geologists. To mention only the most recent instance, I learned that the idea of Assam as a resistant pivot, round which the far eastern block probably drifted south-westwards into its present position, has also been recently expressed on geological grounds by M. Fromaget,[8] Director of the Geological Survey of Indo-China. Lastly, it was gratifying to find that at the Amsterdam Congress Professor Jongmans expressed ideas essentially similar to those presented in my paper, read the same day.

With so much concurrence on the essential points, I think that we may feel satisfied about the stability of our main conclusions. About ten years ago, in an essay on a broad survey of the "Southern Fossil Floras",[9] I said that it was the scattered distribution of the previously glaciated areas of Gondwana Land that provided the main support to Wegener's hypothesis: palæobotany did not seem to me at the time to lend any clear evidence in favour of it. The Carboniferous glaciation of the southern hemisphere still appears to me to be the main pillar on which Wegener's idea rests. But I now feel that palæobotanical considerations, such as those set forth above add another, though modest, support to this remarkable theoretical edifice, at least so far as concerns the movement of continental masses through wide ranges of latitude and longitude.

Antiquity of Lac and Superstitions Connected with It.

By M. Sreenivasaya.

(*Department of Biochemistry, Indian Institute of Science, Bangalore.*)

THE Indian Lac Industry enjoys a venerable antiquity dating as it does to the times of the Puranas. Reference to lac is made in "Mahabharata" in connection with the "*Laksha Griha*" or palace of lac, which was built to ensure and burn down the Pandavas. Kautilya mentions the product in his celebrated "Arthasastra". Coming down to very recent times Abu-l-Fazl who was in the Court of Akbar, refers to lac as being employed for varnish making.

In Ayurveda, lac is extensively employed, both for external application and internal administration. Shellac, finely powdered and mixed with honey, is given as a specific for hæmostosis. It forms one of the main ingredients of a medicated oil known as *Lakshadi Thaila* which is reputed to bring down chronic fevers, cure rheumatic pains and help the growth of fœtus during pregnancy. Decoctions of lac are administered to consumptive patients with good effect. Germicidal, febrifuge and astringent properties are attributed to lac. It is not clear to which constituent of lac the medicinal property is attributable. When decoctions are made, the body fluids of the insect which go into solution are involved but when the medicated oil is prepared, the wax and the insect fat dissolving in the oil, constitute the effective ingredients. It is not clear whether brood lac consisting of all the living insect mothers or the "*phunki*" lac containing only the dead insect bodies, is used. Local information points to the conclusion that the most effective and potent preparations are those made from brood lac which is not always available to the Ayurvedic Pundit. It is quite conceivable that the medicinal value of the wild lac is higher than that of the commercial species.

This ancient industry is naturally connected with a number of "superstitions" some of which appear to have a sound scientific foundation. Those who generally cultivate lac form a caste by themselves in Mysore, and they observe these superstitions in a most religious manner. The uncertainty which characterises lac crops is signified by the saying that "the ferry boat, lac and Tasar depend on God". These three things cannot be controlled by human beings. It is believed that all lac-bearing plants are haunted by evil spirits which are responsible for all kinds of damages and crop failures. To propitiate these evil spirits and invoke their good favour, rams, goats and chickens are offered to them in sacrifice.

The solar or the lunar eclipse, especially when it synchronises with either the swarming of larvæ or the emergence of males, is believed to be fundamentally calamitous to lac crops. On such occasions it is not unusual to find liberal animal sacrifices being offered in the field.

Host plants need a change of physiological condition before they can bear bumper crops of lac and the desired change can be brought about by repeated lac infections and successive prunings for several consecutive years. This is an observation of great value and is fully borne out in modern field practice; but an adequate scientific explanation of this observed fact cannot at present be given. The successive infections and prunings will result in altering the ratio of top to root to the optimum point.

Brood lac should not be harvested until the larvæ are seen to swarm out of their mother-cells in pretty good numbers and

settle on the tender positions of the shoot at least to the extent of about 4 inches. There is much to be said in favour of this recommendation although the latter half may have to be modified to a certain extent.

The insects resulting from prematurely cut brood lac generally lack in vigour and do not build up healthy encrustations. This is an observation with which all practical lac growers will entirely agree.

Those of the insects which swarm out in the first stage are the best since they are found to build up the thickest encrustations and maintain a vigorous state of health. Those which swarm out subsequently are weak and suffer from heavy mortality for one reason or other.

Lac does not grow at the tip of the branches.

Brood lac should be used for infecting soon after they are collected. If it be desired to keep them longer for a day or two, they should be stored up in a cool place buried under paddy husk, which prevents the profuse and rapid swarming of larvæ. This highly suggestive observation can be extended to an alteration of swarming periods within wide limits, with the ultimate idea of controlling the rate of swarming in accordance with climatic factors which may be prevalent during the period. This problem of artificially controlling the rate of larval swarming has an important practical bearing which will be referred to later.

Swarming of insects commence with the rising of the sun and cease with the setting.

Lac insects are very sensitive. On cloudy days or in chilly weather, they do not swarm out of their mother-cells. In the course of swarming, if it suddenly commences to rain, with a consequent fall in temperature, the insects are said to go back to their mother-cells, which is a fantastic idea. Under heavy showers the larvæ get washed out and have not been observed to return to their mother-cells.

Insects swarming out of the mother-cells, come down straight to the ground and then crawl up the trunk and branches and strive to find suitable places. It is believed that without first touching the ground, by way of propitiating mother earth who gave them life, the young larvæ do not commence their careers.

The man who infects lac is expected to observe certain religious rites until the "*phunki*" lac is removed from the host plants. He is prohibited from having a shave, nor can he take an oil bath. It is believed that a violation of these injunctions will lead to the branches appearing clean shaven and besmeared with oil, deprived of all encrustations which would be built up if the operator religiously observes ceremonial usages.

On the day, when "*phunki*" lac is collected from the host plant, milk is boiled underneath the host plants in a new earthenware pot. The vigour with which milk boils and foams over is taken to be an indication of the future abundance of the white filaments characteristic of healthy and bumper crops.

Hail storms and fogs do not favour the growth of lac.

If it rains in the month of January palas lac may die while April rains are fatal to kusum lac. These represent two particular rains known as salt rains which are not favourable to lac propagation.

A single cell of kusum-brood lac is equivalent to a stick of palas-brood lac.

This is supposed to give us an idea of the relative number of insects in the two different varieties of brood lac.

Lac is supposed to grow very well on the lower branches during the rainy season and on the top branches during the winter.

Most of the observations which have been detailed above, have a scientific bearing and are doubtless the result of keen observation while some of them appear to be highly fantastic.

Lt.-Col. A. D. Stewart, C.I.E., I.M.S.

It is unfortunate for India that those who serve her in an official capacity must retire at about an active middle age. New recruits are constantly joining to fill up the ranks but just as constantly do the senior and experienced ones resign when they are so capable of carrying on for many further years. In September 1935 Lt.-Col. A. D. Stewart gave up his appointment as Director of the All-India Institute of Hygiene and Public Health and Professor of Hygiene in the School of Tropical Medicine, Calcutta, in order to take up the post of Superintendent of Edinburgh Royal Infirmary.

Col. Stewart is, as we all know, a native of Scotland. He was born in 1883 and after terminating his school days in Dux he entered Edinburgh University as a Medical student in 1901. He graduated in 1906 and entered the I.M.S. in the same year. From 1907 to 1931 he was in military employment, and just before the War was Medical Officer of Health, Simla. During the Great War he saw much active service, serving in Egypt and the Suez Canal area, at Gallipoli and the landing at Cape Helles, in the Senussi expedition in Western Egypt, in Mesopotamia and as surgical specialist on the hospital ship *Vasna*, and finally as D.A.D.M.S., Bombay. He was mentioned in the final war despatch by the Government of India.

On reverting to civil employment after the War, Lt.-Col. Stewart served from 1919 as Medical Officer of Health, New Delhi,—a post which called for special qualifications as the laying-out of the Imperial Capital involved many serious problems of public health.

In 1921 he came to Bengal and served in turn as Director of the Bengal Public Health Laboratories, Director of Public Health, Bengal, and Professor of Hygiene at the Calcutta School of Tropical Medicine. In 1926–1928 he was appointed Principal of the Calcutta Medical College, and had a very strenuous time in reorganising that institution and putting it on a sound basis.

In 1929 the scheme for an All-India Institute of Hygiene and Public Health matured, and the construction of the building and its equipment were undertaken by the Rockefeller Foundation at a capital cost of Rs. 16 lakhs. Lt.-Col. Stewart was selected as Director Designate of the Institute in 1929, and in 1932 became its first Director.

Col. Stewart's knowledge of public health conditions in India and, Bengal in particular, was both wide and practical. His main experience in the field was gained as Director of the Public Health Laboratories. Consequently when the Rockefeller Foundation proposed the Institute in Calcutta, they clearly saw that Col. Stewart was the man to whom the design and the Directorship should be given. While holding this post Col. Stewart was in an ideal position for utilising his knowledge and experience. There was hardly a problem or inquiry into public health conditions of Bengal in which he was not consulted. He was Chairman of the Conference of Cholera research workers in India where his capacity for appreciating not only the main issues of field work but also the finer details of antigenic structure, were of inestimable value in guiding the diverse activities of the members as a whole. He was also a member of the Malarial Advisory Committee of the Bengal Sanitary Board where again his intimate knowledge made his opinion of great weight. One of his last meetings was on an inquiry into the Calcutta Water Supply, the administration and technical working of which he probably knew more about than any other member. In 1933 he was appointed by the Government of India—as their representative at the Office International d'Hygieno Publique at Paris where his views on such international problems as cholera were carefully listened to.

Other Activities.

His valuable work for the two medical institutions in Calcutta, however, does not complete the story of Lt.-Col. Stewart's manifold activities in Bengal. For twelve years he has been an active and zealous Fellow of the Calcutta University, and that institution owes much to him for his help and advice with regard to its public health diplomas. He has also served for many years on the State Medical Faculty of Bengal, the Bengal Council of Medical Registration, and in connexion with the inspection and regulation of medical schools and colleges throughout the Province.

He has for many years been prominent in connexion with the work of the St. John's Ambulance Brigade in Calcutta, and was for

two years Assistant Commissioner of the Calcutta District.

Members of the Staffs of the All-India Institute of Hygiene and Calcutta School of Tropical Medicine will lose, with Lt.-Col. Stewart's retirement, the services of a most loyal and devoted colleague, and a teacher of wide experience and specialised knowledge.

In addition to Lt.-Col. Stewart's own work, mention must be made of the services of Mrs. Stewart on many social and public health committees in Calcutta, and especially in connexion with the annual Calcutta Health Week.

Lt.-Col. Stewart has published many papers on public health and medical research subjects in the *Indian Medical Gazette* and the *Indian Journal of Medical Research*. He was the author of manuals on tropical hygiene and public health laboratory practice. Many of these were devoted to the question of sewage inactivation and water purification, a result of which was a valuable suggestion for the improvement and economy in the use of alum. He also published a considerable amount of extremely important work on the bacteriology of food, sewage and water while in charge of the public health laboratories. His work in Bengal during the last 15 years has contributed very materially to raising the standard of public health in the Province and towards the solution of Bengal's many and difficult problems in health welfare. He received the C.I.E. in 1934 in recognition of his valuable services to India.

Col. Stewart was a man of interests extending far beyond his work. He was keenly interested in music and while serving with a Gurkha Regiment in his early days he wrote down and collected a number of their folk melodies. He neglected no opportunities for taking up other hobbies as the above illustration shows and Geology was similarly studied not from books but from direct observation in the field. Among the numerous other activities in which he joined and encouraged was the Bratachari movement in Bengal which aims at the revival of folk music and dancing. He was widely read and never failed to be an interesting conversationalist both light and serious. During his last few years in India in spite of the many demands made on him he illustrated in no small degree the rule that the busiest man has always time to spare. No one left his room without getting his full attention, courtesy and help. He had a shrewd judgment and always grasped the main issue whether of a scientific or administrative problem. His criticism was always followed by other constructive suggestions a rare asset, which no doubt contributed largely to the continual stream of work with which he had to deal.

Both Col. and Mrs. Stewart were liked by all with whom they came in contact—no mean accomplishment—and there can be no doubt that Edinburgh has chosen wisely in recalling one of her graduates, who, we all hope, will have many more years of happiness and service in his new appointment.

H. ELLIS C. WILSON.

Craters in the Moon.

DR. F. E. WRIGHT of the Geophysical Laboratory, Carnegie Institute of Washington, recently announced before the National Academy of Sciences, his observations on the relation between the number and size of the craters on the moon. Craters with diameter of 4—8 miles are grouped in one family; those with 9—13 miles, in another and so on. The graph showing the relation between size and number is a smooth curve which is interpreted to mean that the "craters are the expression of a single mode of formation, such as volcanic, or meteoric impact or some other type". "The craters are remarkably circular in outline. The small craters have the aspect of simple depressions with walls which rise only slightly above the level of the surrounding country. They are more of the nature of pits or holes in the ground, not unlike the crater holes produced by the impact of an explosive bomb. As the size of the crater increases, the crater floor is less even and usually contains subsidiary craters and elevations."

Letters to the Editor.

The Mathematical Theory of a New Relativity.

In the September number of *Current Science*[1] some criticisms by "B. S. M." of my Theory have been published. I heartily welcome such criticisms because they give me an opportunity to elucidate the points which may not be clear. I am briefly replying to the criticisms in the various paragraphs seriatim, reserving a more detailed examination for a later occasion.

§ 1.

1. I have never claimed that my Theory deserves Harlow Shapley's characterisation of it "as one of the high lights of astronomy," and I myself was surprised at the generosity of his remarks. It is a mere presentation of a new Theory still in its infancy which, applying Newtonian principles, with necessary corrections, claims to deduce the formulæ which are the pride of Relativity. It is not for me to say anything as regards the insinuation that Shapley's reference was not based on a critical study of the article.

2. D. R. Hamilton's criticism that my of the advance of perihelion to "absurdly erroneous" results has been met by me in Chapter VI of my paper.[2]

3. "On the mathematical side not much notice has been taken."—The critic refers to the mention of my article by the Zentralblatt fur Math., and omits to refer to the *American Mathematical Monthly*.[3] He has not also referred to *Nature*.[4]

§ 2.

4. His objection to the choice of the name "A New Relativity," needs no notice. I am certainly "vehemently opposed" to the extraordinary assumptions of Einstein's Relativity, but in no way to a "principle of Relativity in any form whatsoever". I maintain that Einstein's postulates are only approximately and not exactly true.

5. I gladly welcome the admission that "Relativity is not the only example of a physical theory which appears absurd when its logical consequences are pushed to their very limit." The very fact that the Principle of Relativity (special as well as general) has been unable to make any substantial progress from any other hand except that of its creator, and even not much from him since 1916, shows that it is not the last word on the problems which it claims to solve.

6. The quotation from Jeans' *Mysterious Universe* at page 228 is not objected to, and the page of the book also was correctly given. But the critic has pounced upon a misprint and expressed his curiosity at finding this mistake in the list of references at the end. Unfortunately there were no less than 13 misprints in the first paper already pointed out in the *Errata*, and there are more misprints in the second paper other than the two mentioned by the critic, which have been corrected in the second *Errata*.

7. "There are some misstatements of fact in the author's references to Relativity the most serious of which are in connection with the observational verifications of the general theory of Relativity."—I shall deal with the subject at considerable length in Chapters X, XI and XII of my next paper, which will show that the claim of Einstein's General Relativity that it has been verified is unfounded.

8. He considers that Chazy's observational value for the advance in the longitude of perihelion of Mercury is "the best observational data".—I suppose it is a great pity that although Chazy's value was published in 1926,[5] it was overlooked by Eddington in his later works. The critic is obviously unaware of the more recent literature to be discussed in Chapter X, which will also show the great uncertainty due to certain assumptions in the calculation of the advance of the perihelion. So much so that von Gleich has actually asserted that the supposed excess of motion of the perihelion of Mercury does not exist and the Newtonian theory of gravitation needs no correction by Relativity.[6]

9. He considers that "the most satisfactory data (on the deflection of light) available at present" are those of Campbel and Trumpler.—This is relying on a rather stale literature of 1923 in ignorance of the bad exposure made by Freundlich (quoted in Chapter II, p. 25) that if necessary corrections are introduced, the three cameras of the American Expeditions of 1922 give the values 2″·20, 2″·30 and 2″·10 respectively.[7] Freundlich has discussed in detail all the previous works including those of Campbel and Trumpler and shown that the value obtained by the latter was due to an inaccuracy in balancing the observations and that their value of the deflection also is 2″·27. It will perhaps shock the critic to learn that Lanczos, a great worker on Einstein's Relativity, has also pointed out that with the necessary corrections Campbel and Trumpler's value comes to 2″·20.[8] Of the three tests, the deflection of light is the only one that is reliable, and in this Relativity has already failed.

10. (i) The later observations of St. John[9] as regards the shift of spectral lines of the Sun are supposed to be "quite satisfactory".

It will be shown in Chapter XII that the agreements are found only for different arbitrarily chosen levels for the centre and the edge, there being marked positive and negative residuals for higher and lower levels. The discrepancies range between $\pm$ 25 per cent. which can hardly be called "quite satisfactory". The discrepancy at the edge is conveniently explained by some unknown "edge effect". The discrepancy is greater when the average of $M\Sigma\left(\frac{a d\lambda}{\lambda}\right)$ is taken, which alone is the correct method. It is well known to every worker on solar physics that wave-lengths on the Sun may differ from those measured on territorial sources on account of a large number of causes.

11. As to the companion of Sirius the assumption of the "quite satisfactory" result is based on Adam's observation.[10] But Vyssotshiy[11] has shown that the density of the companion of Sirius is much less than what has been assumed so far and therefore the radius much larger. If Einstein's value is correct, then so is mine!

The following are stated to be "misstatements of a minor nature":—

12. (1) "Relativistic invariance holds in vacuum only".—Schwarschild's particular solution is of $G_{\mu\nu} = 0$. As to this Eddington says, "This is the state of the world in an empty region—not containing matter, light or electromagnetic fields, but in the neighbourhood of these forms of energy."[12]

13. "Einstein arbitrarily assumes $C + v = c$ and $c - v = c$."—In relativity the velocity of light is absolute and relative to every frame of reference is the same. Even if two systems S and S′ be moving with relative velocity v, "the resultant velocity relative to S′ is c, the velocity relative to S is also c, whatever the direction".[13]

14. "Milne's theory ignores gravitation and evades collisions."—Compare "The new theory shows that the expansion is in reality a natural phenomenon taking place in the absence of gravitation and proceeding in

spite of it" (p. 2) and "consider a swarm of particles moving in straight lines, each with a uniform velocity without *collisions or other interactions* possessing an entirely arbitrary velocity-distribution" (pp. 6–7).[14]

15. "In Relativity time is wholly imaginary and space illusory."—The unit of time is really $\sqrt{-1}$, and space has four dimensions. What more imaginary and illusive character is wanted than the confusion of space and time?

16. (1) The mathematical part of the work is "quite elementary and does not go beyond the solution of an ordinary differential equation of the second order".—No reference to any book or paper is supplied where even an approximate solution of my equation (5·9) was given before, much less the exact solution. The so-called elementary solution is by successive approximations covering two pages and a half.

17. "Looking from an æsthetic-mathematical point of view one searches here in vain for such concepts like (as) groups, tensors and generalised spaces characteristic of Relativity or functional equations, sets of points, and Finsler spaces relevant to Milne's new Relativity."—The author thinks that paper which does not use Tensors, Groups and other branches of higher mathematics is not a valuable paper at all. Such a suggestion will condemn workers like Maxwell, Bohr, Sommerfeld and many other illustrious investigators, both dead and living. In fact the claim of the New Relativity is that its formulæ are deduced on simple dynamical principles without recourse to such methods. It is not easy to appreciate what objection there can be to its simplicity.

18. Some differential equations are considered to be "not relevant".—Apparently the critic thinks that the complete theory is contained in the five Chapters already published. More have come out since.

19. (iv) The superiority of method over those of Forsyth, Morley and Pierpoint is said to have been "achieved at the cost of a little wrong mathematics". It is conceded that the solution (9·5) is "correctly obtained" but it is asserted that the next solution has been obtained wrongly. The critic says, "It is, however, absurd to use this theorem here since it cannot apply to non-linear differential equations, and moreover is not a particular integral."—It was pointed on pages 10 and 11 that for Mercury $\frac{\mu}{h^2} = 1\cdot73+10^{-13}$ and u also is nearly the same, and that k was of the order 10^{-4}. Also θ varies from 0 to 2π. It was accordingly considered too obvious to mention that the second power of $\frac{\mu}{h^2}$ $(1-2k\theta)$ as well as the product $\frac{\mu}{h^2}(1-2k\theta)$. u were negligible. If this obvious fact were borne in mind, it will be found that the general solution given by me is perfectly valid. The correctness of the solution can be easily verified by direct substitution in the differential equation. It is some consolation that the solution in elliptic functions is not called "quite elementary". The critic has not noticed the misprint $\frac{D^4}{\mu^3}$ for $\frac{D^6}{\mu^3}$.

The following observations are regarded as contrary to scientific investigations:—

20. "Nature's limits are not fixed by our capacity to observe them."—Does Nature exist only when seen by man?

21. "Relative velocity cannot mean relative velocity as actually observed, and we cannot go by measurements only."—This is a rather bad paraphrase of my remark "if relative velocity only means relative velocity as actually observed and we go exclusively by measurements only, then the relative velocity between two bodies would depend on the particular method of measurement which is chosen". This remark was in anticipation of Chapter VII, which will throw fuller light on the point.

22. "A certain concept in Relativity is unacceptable because the concept is philosophically an impossible one."—The concept referred to is, in physical language, that there exists a mysterious cosmic force of repulsion, which not only acts at a distance, but increases in intensity as the distance between the two bodies increases.

I am not the first critic to find fault with his conception. Even Einstein has been aware of the weakness of his argument and has been trying to change the assumption. In fact in a paper published in the *Proc. Nat. Acad. of Sciences* jointly by Einstein and de Sitter, λ was taken to be zero. In Cosmos, de Sitter concluded that the theory of the expanding Universe is less definite than it used to be and that we do not even know whether the curvature is positive, zero or negative, whether the universe is finite or infinite.

23. A whole paragraph is devoted to commenting on a reference to Jordan's paper in a short note at the end. It has been repeatedly emphasised over and over again in my papers that the existence of gravitons is not necessary for the Mathematical Theory.

§ 3. GENERAL RELATIVITY.

(*a*) *Advance of Perihelion.*

24. The critic says that there is "no novelty of ideas" as they go back to the work of Laplace, whose theory produced secular perturbations or, in the alternative, a high velocity of gravitation.—Obviously the critic, who has quoted profusely from the *Encyclopædia*, is not aware that Lorentz and Eddington have shown that even on Laplace's own theory perturbations could vanish to the first order terms (see Chapter VII). It has also not been mentioned by the critic that Laplace's theory was based on the idea of pressure caused by a liquid ether owing to which the velocity of propagation was directed from the attracted body towards the attracting body, whereas in my theory, the gravitational influence is propagated equally in all directions outward from the influencing body towards the influenced body, the change of sign making all the difference.

25. It is irrelevant to refer to other theories including Anding's which assumed a new law of gravitation quite *arbitrarily*, and yet did not succeed in getting any satisfactory results. It is one thing to assume arbitrarily a new law of gravitation, and it is quite another thing to deduce a new law from a single assumption of the finiteness of the velocity of propagation. I may mention that if one were to assume a new law of gravitation, I would take it to be $-\frac{\mu}{r^2}-\frac{3\mu h^2}{D^2}\cdot\frac{1}{r^4}$ which will give all the results we want and avoid all difficulties (see Chapter VII).

26. "Remembering that Sulaiman's correction factor does not depend on r, the criticisms levelled against Gerber's theory therefore apply to Sulaiman's theory equally well."—Gerber's theory (referred to by me in Chapter I, p. 4) involved the propagation of potential with finite velocity which Seeliger, Laue and Oppenheim rejected as being impossible. Gerber had also misapplied the Lagrangian equation as pointed out by Pauli. Neither of these defects can be found in my theory. Also my factor is a function of dr/dt which is a function of r, and is therefore not derivable from Gerber's potential.

27. Following in the footsteps of D. R. Hamilton the critic has emphasised at several places that my theory would lead to unforeseen perturbations, and either Mercury would go off in three centuries or the velocity of gravitation should be thousands of times more than that of light.—My replies to Hamilton's criticisms are to be found in Chapter VI, which may be referred to. As Laplace's theory led to a retardation, he was unable to explain the perturbation. My theory leads to an acceleration of motion, which can be adequately explained by the resistance of the medium through which planets pass, as is now becoming clearer from the explanations of Zodiacal light and Gegenschein phenomena. This material difference saves my theory from foundering on the rock on which Laplace's theory did.

28. It is wholly unnecessary for me to discuss the other theories relating to the advance of Mercury's perihelion. The principal defect in Einstein's theory is the unconvincing nature of its fundamental assumption of the absoluteness of the velocity of light.

(*b*) *Gravitational Deflection of Light.*

29. "Gerber's equation does not yield the value for the deflection which is certainly true, and the same should also be true of Sulaiman's equations if properly handled."—The critic has undertaken to rehandle in two ways my equations which, as shown in Chapter VII, was obtained for heavenly bodies where v'/D is small.

30. (i) He does "the straightforward thing....to write the equations of motion *ab initio* using the relation $v = D$" and curiously gets $\frac{d^2u}{d\theta^2}+u=0$. He has apparently forgotten that, as noted on p. 8, v is the velocity along $S'P=\frac{dr}{dt}\cos\alpha-\frac{rd\theta}{dt}\sin\alpha$ and not along the tangent.

31. (ii) He has verified his result "qualitatively" by putting $v = D$ in $-\frac{\mu}{r^2}\left(1-\frac{v}{D}\right)^3$. [The critic has been freely using such expressions as "absurdly erroneous", "completely false impression", "most serious misstatement", "quite elementary", "drab", "absurd to use this", "results completely against all observed values", "arbitrary", "truly amazing".] But I would refrain from using any epithet for the

critic's mathematics according to which for a light particle no matter howsoever much inclined it may be to the radius vector the form always is $-\frac{\mu}{r^2}\left(1-\frac{c}{D}\right)^3$. This is the supposed "consonance with Gerber's equation"!

32. "When the (author) states that $r\frac{d\theta}{dt}$ can never exceed the *tangential velocity* c, he assumes unconsciously that the tangential velocity is constant, but this certainly cannot be true."—There has never been any such assumption which would be contrary to my theory. I said on page 29, "it disproves the assumption in Relativity that the velocity of light in a gravitational field remains constant". But undoubtedly the change in the velocity c is extremely small.

33. "The assumption of a constant tangential velocity is equivalent to taking the central orbit as circular, and it becomes meaningless to talk of the deflection as the angle between the asymptotes of the orbit."—With the disappearance of the constancy of the velocity, the "meaninglessness" vanishes and so does the circular orbit.

34. The "third mistake" is said to be that "by showing that the least value of the expression is....the conclusion is drawn that the deflection is exactly 4/3 times the Einstein value".—It is not clear where the word "exactly" has been got from. He has apparently misread the word "nearly". On the equation, that was the minimum value only, and the critic has himself quoted my words "at least".

35. "One would naturally inquire what would be the maximum deflection possible, but the work is silent on this point."—It is shown in Chapter VII, section 5, that on that equation the maximum deflection would be 3/2 times Einstein's value. But it will be shown in Chapter XI that in the case of light the equation is only approximately true and not exactly so, thus giving a smaller value for the deflection.

(*c*) *The Shift of Spectral Lines.*

36. "No remarks appear to be necessary in this case, for according to the author's own showing the corrections provided by the New Relativity are not appreciably large and the value of the ratio is the same as Einstein's."—Apparently the critic considers that there is no credit whatsoever in obtaining on purely Newtonian principles the same value for the spectral shift, as is obtained in Relativity with the help of extraordinary assumptions and cumbersome mathematical apparatus, and by treating an electron at the Sun as being "momentarily at rest", a self-contradictory assumption.

37. The value of the shift was the same as Einstein's for light from the centre of the disc.—In the Appendix to Chapter II it is shown that as regards the shift from the limb, there is an appreciable difference in the two values. In Chapter XII (see No. 10 above) St. John's average values will be examined.

38. "No one would seriously think of adopting it as an alternative to the General Theory of Relativity for the explanation of gravitational phenomena."—I can never expect that my theory will be accepted until more accurate future observations are forthcoming to disprove Relativity still more thoroughly.

§ 4. SPECIAL RELATIVITY.

(*a*) *Relative Velocity.*

39. (1) As the Theory is a new one, it is not at all surprising that critics should feel some difficulty in the early stages of its development. In Chapter VII it has been explained that relative velocity must vary with the method of observation. The whole object of obtaining the formula for the compounding of velocities was to show that *if a messenger's double journey method be adopted*, a formula can be obtained which as an approximation would reduce to a form similar to Einstein's. Einstein has assumed his formula to be rigorously true, from which unconvincing results follow in the extreme case. If his formula were taken to be approximately true only so long as the velocities of the bodies are small compared to that of the messenger, I would have no quarrel with it. Indeed, all the results of Relativity can be incorporated in the new Theory within the limits of such an approximation.

40. "Where u and v' are velocities relative to an observer who is at rest in his own system."—In absolute space, "rest in his own system" is not the same thing as absolute rest. *If the messenger's double journey method be employed*, the relative velocity as measured must necessarily be slightly different from Newton's relative velocity.

41. "As an example of confused thinking it is hard to find anywhere in relativistic literature a parallel to the author's derivation of the equation."—Failing to grasp the essence of the theory, the critic has become

angry and uses strong language. Of course, what is not grasped must necessarily appear to be confusing.

42. "An absolute distance between two moving points is assumed as r independent of all measurement."—For Newton's absolute space and time, such an assumption is perfectly sound. My point of view is Newtonian, and the statement is in strict logical agreement with the whole trend of such thought.

43. (1) The critic "deduces an absurd consequence" by putting $v' = D = c$.—Apparently he seriously thinks that *for a double journey method* also $v' = c$, as if a messenger travelling with velocity c can overtake another body travelling away with the same velocity, and thereafter return to his source! But if $D > v'$, then on this double journey method the value for a receding body tends towards the limit $v = c - \frac{u}{2}$ which is simple dynamics. The notion of "hybrid form" is the outcome of ignoring that the method of ascertainment is a method of *the double journey of the messenger.*

44. (ii) *Fresnel's Formula.*

The relative velocity formula *according to the double journey method* is not only a function of the difference between two absolute velocities, but also a function of the individual absolute velocities themselves. It was only as an approximation that it was applied to Fresnel's experiment. For a higher approximation the formula derived on the *messenger's double journey method* would be inappropriate for Fresnel's experiment, because there the two parts of the beam though travelling in opposite directions relative to the moving water perform *only one* and *not a double journey.*

This clears up the discrepancy. The object of the new theory is to explain phenoména by applying well-known rational principles without the postulates of Relativity. So far as Fresnel's water experiment is concerned, he had himself explained it on a simple physical principle of a change in the velocity of light.

45. The transformation formulæ on pages 247–48 have been summarily dismissed as "ridiculous analogues".—They merely indicated a different method of arriving at nearly the same formula, and have not yet been actually applied. The significance of the difference will appear from Chapter VII.

(b) *The Principle of Aberration.*

46. "It is difficult to see any justification for the reduction in the intensity of force along its apparent direction. It really makes no sense to say that when the velocity of flow is D, the effective component of force observed along the apparent direction is D cos α."—It makes no sense because the word "apparent" which did not occur in the text (p. 250) has been interpolated. The dynamics of a force moving with a finite velocity is unique, and difficulty of its conception is great. As a matter of fact, it will be seen from Chapters I and VIII that the equations have been obtained on the hypothesis that there is no change in the magnitude along the resultant; and the consideration of a change in magnitude, as pointed out in Chapter VIII, has been postponed.

47. "There is an utter confusion here between velocity and force. This confusion is also responsible for the meaningless phrase 'the velocity of light ON a body moving with volocity v''."—The critic has made a capital out of the misprint in which the word "falling" was unfortunately left out after the word "light".

48. "The claim of universality is belied by assuming that in the case of light the velocity is reduced while in other cases the intensity of force is changed (for example, H in the explanation of Bucherer's experiment)."—The effective magnitude in both of these is changed because it is only their component that is effective.

49. "There is yet another inconsistency .... The universality claimed would certainly require Newton's law of attraction to be $-\frac{\mu}{r^2} : \left(1+\frac{v^2}{D^2}\right)^{\frac{1}{2}}$ leading on to Gerber's equations, but the author uses, instead, the factor $\left(1-\frac{v}{D}\right)^3$."—A reference may again be made to the Appendix (IV, pp. 259–60) which shows how the factor is derived. A further reference to Chapter VII, section 5, is invited.

50. The critic says that "it is impossible to see how $c_1 = c \cos \alpha$ and $\tan \alpha = v/c$ can be both simultaneously true where c_1, the apparent velocity of light, has its direction perpendicular to that of v, and α is the angle of aberration".—If the critic means that $c_1 = c \cos\left(\sin^{-1}\frac{v}{c}\right)$ and $c_1 = c \cos\left(\tan^{-1}\frac{v}{c}\right)$ cannot both be simultaneously true exactly, it is of course so. When v is small, the

first approximation gives $c_1 = c\sqrt{1-\frac{v^2}{c^2}}$ which can be transformed into Minkowsky's equation, in which v cannot be greater than c.

But when v is large, $\tan\alpha = v/c$ is the more accurate formula and then the second approximation gives $c_1 = c\cos\left(\tan^{-1}\frac{v}{c}\right)$ which yields

$$c_1 = \frac{c}{\sqrt{1+\frac{v^2}{c^2}}}$$

for which v can be even greater than c, even up to ∞.

51. "It is on the basis of such 'flawless' mathematics that the possibility of velocities up to ∞ is deduced, and one might well suggest to the author the derivation of his first universal principle when one of the bodies is moving with such a velocity, for example, the velocity greater than that of the messenger employed."—Apparently the critic labours under the impression that even when the velocity of recession is greater than that of the messenger the double journey method would hold good. Comment on this is unnecessary, because there can be no double journey in such a case.

(*c*) *Michelson and Morley Experiment.*

52. "By using the author's own universal principles it can easily be shown that this explanation is untenable."—The critic says that the formula should be replaced by

$$\frac{l}{c-\frac{v}{2}} + \frac{l}{c+\frac{v}{2}} = \frac{2lc}{c^2-\frac{v^2}{4}}.$$

(1) This is an obvious misapplication of the formula obtained by *the double journey method* to two *single journeys* of light. If the times for the two journeys to and fro are to be calculated *separately*, the double journey formula cannot possibly be applicable.

(2) If a double journey formula is insisted upon then the *whole* double journey should be taken as one journey and the Corollary (IV, p. 247) which gives the ratio of the apparent and real velocities should be applied, giving instead of the apparent time $\frac{2l}{c}$ the real time $\frac{2l}{c\left(1-\frac{v^2}{c^2}\right)}$.

53. The critic says that the second universal principle has been applied wrongly and that after the direction of flow has been once shifted by an angle α and the velocity changed from c to c_1, "it is therefore wrong to again compound c_1 with v, and hence the time should be replaced by $\frac{2l}{c_1}$".—In reality there is no second compounding at all. When falling on the moving surface the light is shifted forward, and its component along AB′ which alone will reach

$$A'' = c\sqrt{1-\frac{v^2}{c^2}}$$

and the time is given by

$$c_1^2t^2 = l^2 + v^2t^2 \text{ or } 2t = \frac{2l}{\sqrt{c_1^2-v^2}}.$$

In the New Relativity the reflection of light from a moving mirror is different from that from a stationary mirror. The effective incident ray is deflected forward and the effective reflected ray deflected backward by the same angle; but the ray which reaches A″ is the component of the deflected ray along AB′.

54. According to the critic the difference in times should be $-\frac{l}{c}\cdot\frac{v^2}{2c^2}$ which he says "can certainly be measured, but is contradicted by the null result of the Michelson and Morley experiment".—It has been shown above that his deduction of this difference is wrong.

(*d*) "*Fine Structure of Spectral Lines.*"

55. There was no attempt made to give any quantitative explanation, but only an indication was given in anticipation of what was to follow. The critic has wasted unnecessary words on what he naturally regards as "really a complete mystery". It must be so, until the method is announced.

5. COSMOLOGY.

56. "The only positive result is the derivation of Hubble's famous velocity-distance law."—Apparently the validity of the derivation of the equation is not challenged.

57. "This cosmological principle can be considered as a particular form of Milne's principle of equivalent observer's."—This is perhaps some admission that the principle is sound even from the relativitist's point of view, though it is a particular case. In fact my principle of the constancy of the ratio of the acceleration to velocity is quite different from Milne's principle of "equivalent observers".

58. "It is quite redundant for the purposes of deriving Hubble's law to invoke the aid of an emission theory of matter which calls to aid supernatural agencies for the

production of gravitons by the explosion of a sub-atomic shell."—The critic has overlooked section 5 (IV, pp. 236–37) where it is pointed out that the existence of gravitons is not at all necessary for the theory; light corpuscles are in themselves quite sufficient.

59. Starting with de Sitter's observed fact that the velocity of light in free space from the front and the rear of a moving star is the same, the problem was tackled from a purely dynamical point of view as to what would be the effect on the *remaining* mass if light consisted of a swarm of particles. Applying the law of the conservation of momentum and considering as one system a large mass and two particles of light before and after the latter left the former, we get

$$mv + Mv + mv = -mc + Mv' + mc \quad \text{or}$$

$$v' = \left(1 + \frac{2m}{M}\right)v.$$

This shows that the loss of such particles, when emitted owing to internal action and reaction and moving with nearly constant velocity in free space, causes an increased velocity to the remaining mass.

The critic rejects this simple explanation presumably in favour of the Relativity hypothesis that the nebulæ, though apparently dispersed in a three-dimensional space, are situated on a three-dimensional skin of a four-dimensional continuum, repelled from each other by a cosmic force increasing with the distance, resulting in a general scattering of the universe!

60. The last objection is, to borrow the critic's own words, "truly amazing". The critic by a curious method of "a simple change or (of) origin" concludes that "dR/dt has always the same sign as R, *i.e.*, the velocity is one of recession".—This is indeed marvellous. It means that even if a nebula were really approaching our system, we can by a mere change of the origin turn its velocity into one of recession instead of approach. No words are needed to expose such an elementary error. No doubt R may have any direction with the nebula, but it is always measured along the path of the nebula. On page 235 I made it clear that "if a nebula were moving in a direction making an angle θ with the line of sight from the earth and *R measured along that direction* and r along the line of sight, etc." I should have thought that even the diagram given on that page would have left no doubt.

In the new theory the velocity is not like the speed of gravitation in Relativity where "if co-ordinates are chosen so as to satisfy a certain condition which has no very clear geometrical importance, the speed is that of light; if the co-ordinates are slightly different, the speed is altogether different from that of light. The result stands or falls by the choice of co-ordinates."[15]

In conclusion, I may add that my theory is a very humble attempt to offer a dynamical explanation of the phenomena which alone are the justification for the postulates of Relativity. As it deals with such a variety of matters, I am quite prepared to concede that, even though no real mistake has yet been pointed out, there may be some, which, if rectifiable, would be gladly corrected by me. Indeed, I am myself quite conscious that my equations also are only approximately true. The theory is still in its early stages and therefore quite capable of modification. My earnest request to mathematicians and scientists is to examine the theory with an open and unprejudiced mind, and see for themselves whether anything can be made of it. If it can succeed in offering rational explanations of the mysterious phenomena on well-understood dynamical principles, the necessity for the postulates of Relativity would cease to exist, though its magnificent mathematical structure shall ever remain for our admiration.

S. M. SULAIMAN.

WHILE thanking you for having given me an opportunity to reply to Sir Sulaiman's

rejoinder to my critical review, I must confess that I do not feel inclined to undertake again a detailed criticism of the rejoinder. The reading of Sir Sulaiman's reply has left me absolutely unconvinced and, if anything at all, has strengthened the opinions expressed in my original review. I think that the worth of any physical theory is to be assessed not by the thoroughness or otherwise of such criticism and counter-criticism but by the positive achievements to its credit. Moreover, Sir Sulaiman has met a large part of my criticism by referring to future work to be published by him and it is perhaps better to wait for these developments, for, the present Sulaiman theory does not explain anything for which Relativity does not provide an answer. There are, however, some points in Sir Sulaiman's reply, which require a reply.

According to Sir Sulaiman, Relativity has been unable to make any substantial progress from any other hand except that of its creator, and even not much from him since 1916 and this shows that it is not the last word on the problems which it claims to solve. It may be pointed out that nobody ever claimed relativity to be the last word on the subject and physics would be dead the moment its theories became last words. It is also difficult to understand the statement that there has been no progress in Relativity since 1916. Most of the modern theoretical physics has been dominated by relativistic principles and the principle of relativistic invariance has been a guiding factor in the formulation of physical laws. The idea which led de Broglie to formulate wave mechanics must really be considered a great triumph of Relativity. The more recent formulation by Dirac of the theory of the electron is another example of an achievement in relativistic theory. The power of this method has been illustrated recently by Kramers in deriving the spin of the electron from purely classical (not quantum) arguments using relativistic invariance.

Sir Sulaiman maintains, in his reply, that the equations $c + v = c$ and $c - v = c$ correctly represent Einstein's law of addition of any velocity to the velocity of light. Now, Einstein's law of addition of velocities is given by

$$v' = \frac{v + u}{1 + \frac{vu}{c^2}}$$

and if, in this, we put $u = c$, we get $v' = c$. Surely this process is not equivalent to writing $c + v = c$.

I have been represented as thinking that a paper which does not use Tensors, Groups and other branches of higher mathematics is not a valuable paper at all. I never said so, but expressed the opinion that such fundamental notions add to the æsthetic value of a paper. Sir Sulaiman claims simplicity for his theory because he does not use such concepts, but the fact is that, in the last analysis, the solution by a series of approximations of a set of differential equations is certainly more complicated than the fundamental notions of tensors, groups, etc.

"Does Nature exist only when seen by man?" asks Sir Sulaiman. I don't know, but the "principle of observables" which has been a guiding factor in modern theoretical physics and has been so ably applied by Heisenberg would appear to suggest that an answer to this question is beyond the realm of physics.

I now come to the *crucial point* of my criticism of Sir Sulaiman's theory, *viz.*, his alternative to the special theory of relativity. In my criticism, I have shown conclusively that this theory when applied to Fresnel's water experiment gives results quite contradictory to experimental values. Sir Sulaiman evades an answer to this by the remark that in this case the double journey method is inappropriate. Again, he states that this method is not applicable to the case $v' = c$. This shows, therefore, that his formulæ are not at all general and that the general double journey method, of which he makes great use, has limitations which can always be manipulated so as to give the results of relativity. The explanation now offered by Sir Sulaiman in his reply indeed makes this part of the subject more difficult to understand than before. It does not, however, surprise him that critics should feel some difficulty in understanding his theory since it is in its early stages of development. He remarks, "of course, what is not grasped must necessarily appear to be confusing." I might as well retort by remarking that what is confusing cannot certainly be grasped!

I might stop at this stage and await the more detailed examination of my criticism which Sir Sulaiman has promised for a later occasion.

B. S. M.

A Modified Gouy's Balance for the Accurate and Quick Measurements of Diamagnetic Susceptibilities.

THE specimen tube of the Gouy's balance has been modified. The modified tube consists of two tubes of which one is sealed and contains paramagnetic substance and acts as a stopper to the other tube in which the diamagnetic substance is taken. At first the pull due to the paramagnetic substance only is noted and then the combined pull due to para- as well as diamagnetic substances together is read (care being taken that the combined pull should be of attraction). By subtracting the combined pull from that due to the paramagnetic substance only, one can easily find out the repulsion due to the diamagnetic substance.

The force acting on the cylinder along its axis is given by :

$$F_x = (x_1 m_1 - x_2 m_2) H_y \frac{\partial H_y}{\partial x} \quad .. \quad (1)$$

where x_1 and x_2 are the mass susceptibilities of the substance and the medium and m_1 and m_2 are the masses of the specimen and the medium occupying the same volume as the specimen, respectively.

If ω_g is the pull due to the empty tube only, then

$$(\omega_g = (x_g m_g - x_a m_{ag}) H_y \frac{\partial H_y}{\partial x} \quad .. \quad (2)$$

where x_g = mass susceptibility of the glass tube.

x_a = ,, ,, ,, medium.

m_g = ,, of the glass tube.

m_a = ,, of the medium displaced by the glass tube.

If ω_p is the additional pull due to the paramagnetic substance, then :

$$(\omega_p + \omega_g) = [(x_g m_g + x_p m_p) - x_a(m_{ag} + m_{ap})] H_y \frac{\partial H_y}{\partial x} \quad .. \quad .. \quad (3)$$

where x_p = mass susceptibility of the paramagnetic substance.

m_p = mass of the paramagnetic substance.

m_{ap} = mass of the medium displaced by the paramagnetic substance.

If ω_{d1} is the pull due to the diamagnetic substance, then :

$$(\omega_g + \omega_p + \omega_{d1}) = [(x_g m_g + x_p m_p + x_{d_1} m_{d_1}) - x_a(m_{ag} + m_{ap} + m_{ad1})] H_y \frac{\partial H_y}{\partial x} \quad .. \quad (4)$$

Subtracting (3) from (4) :

$$\omega_{d_1} = (x_{d_1} m_{d_1} - x_a m_{ad_1}) H_y \frac{\partial H_y}{\partial x} \quad .. \quad (5)$$

Similarly the pull due to some other diamagnetic substance can be found out and

$$\omega_{d2} = (x_{d2} m_{d2} - x_a m_{ad2}) H_y \frac{\partial H_y}{\partial x} \quad .. \quad (6)$$

Dividing (5) by (6) :

$$\frac{\omega_{d_1}}{\omega_{d2}} = \frac{x_{d_1} m_{d_1} - x_a m_{ad_1}}{x_{d_2} m_{d_2} - x_a m_{ad_2}}$$

$$\text{or } x_{d_2} = \frac{1}{m_{d_2}} \left[(x_{d_1} m_{d_1} - x_a m_{ad_1}) \frac{\omega_{d_2}}{\omega_{d_1}} + x_a m_{ad_2} \right] \quad .. \quad (7)$$

This equation has been used for calculating the susceptibilities of the substances under investigation.

TABLE I.

Experimental Results.

Substance	$-x \times 10^{-6}$ observed	$-x \times 10^{-6}$ from other authors	
Benzene ..	0·713	0·712	Int. Crit. Tables
Bromobenzene ..	0·517	0·505	Bhatnagar
Iodobenzene ..	0·473	0·471	Int. Crit. Tables
p-Xylene ..	0·704	0·736	Bhatnagar
Nitrobenzene ..	0·498	0·499	Oxley
Anisole ..	0·668	0·672	Pascal
m-Bromotoluene.	0·528	0·546	Bhatnagar
o-Nitrotoluene ..	0·526	0·532	Int. Crit. Tables
Pyridine ..	0·620	0·623	Pascal

The results obtained appear to be quite satisfactory as they clearly correspond with the values given in the tables. The experimental error varies between 0·7—1·0 per cent. The disturbances that are produced by the air draughts can be easily avoided. As for the working of the apparatus is concerned, it is found that there is a distinct improvement over the previous methods as regards simplicity and ease of operation.

The author takes this opportunity of thanking Prof. S. S. Bhatnagar for suggesting this method.

Magnetic Susceptibilities of Nitric Acid Solutions.

WE have determined the magnetic susceptibilities of HNO_3 solutions for over thirteen concentrations between 4 and 65%, employing a modified form of the Quincke method with photographic recording arrangement, developed by one of us.[1] The advantage of the photographic method lies in the fact that it enables simultaneous and nearly instantaneous records to be obtained for both the standard and comparison liquids, thus eliminating errors due to non-prevalence of identical conditions.

The susceptibility-concentration curve, as shown in the figure, indicates marked departure from the linear relation. As each point on the curve represents the average of a number of readings which agree to within 0·1%, it is believed that these departures from linearity are genuine. The best line drawn through the points cuts the susceptibility axis at a point corresponding to the value of $-0 \cdot 668 \times 10^{-6}$ for water in solution, which is lower than that for water in the pure state ($-0 \cdot 72 \times 10^{-6}$). The gram-ionic

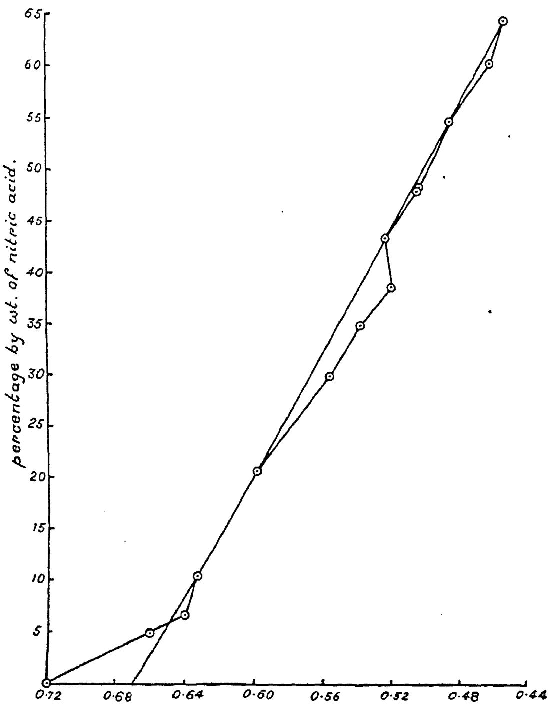

Fig. 1.

susceptibility of the NO_3 ion is found to be $-20 \cdot 83 \times 10^{-6}$ which agrees with the value of $-20 \cdot 1 \times 10^{-6}$ as given by Kido[2] but differs considerably from the value of -38×10^{-6} as calculated by Pauling.[3]

The curve shows four definite minima, corresponding to the compositions, $HNO_3 + 50\ H_2O$, $HNO_3 + 6\ H_2O$, $HNO_3 + 4\ H_2O$, and $2\ HNO_3 + 5\ H_2O$. Although the first minimum cannot be easily accounted for, the other three departures may be attributed to the formation of definite molecular complexes. The existence of such complexes or hydrates has also been indicated by other physico-chemical data, such as freezing point determinations, conductivity, etc. It may be pointed out that the deviations in the case of the last two hydrates are considerably less than those in the first two. This may be explained on the assumption that water which is known to exist in the form of associated molecules is depolymerised at higher concentrations and that the increase in susceptibility resulting from this depolymerisation partly compensates for the decrease, due to the formation of hydrates. Fuller details will be published elsewhere.

The Temperature Coefficient of Susceptibility of Tetra Hydro-Naphthalene.

THE diamagnetic susceptibility of Tetra hydro-naphthalene has been studied at different temperatures, ranging from 23° C. to 25° C., using the Quincke method, with large magnetic fields. The electromagnet used was a large one of the Dubois type. In the experiments, currents used were within 7 amps. and the heating was not appreciable. Care was taken to maintain the current at a particular point. This was effected by having a travelling microscope focussed, on the pointer of an ammeter and any variation of the pointer was corrected by the adjustment of the current, by altering a resistance in parallel with the main circuit.

The tube was thoroughly cleaned first with benzene and then with sodium hydroxide, hot distilled water, and then concentrated nitric acid, and finally with hot distilled water.

The tetralene used in this investigation was kindly supplied in a pure state by Dr. M. Govinda Rau, of the Indian Institute of Science. The tube was filled with the liquid, evacuated and sealed. For observing the depression, a micro-meter eye-piece was used and the usual precautions taken.

The absolute value of susceptibility as determined from the mean of several readings is $-\cdot 688 \times 10^{-6}$. Values were taken at different field strengths and there was no variation with field strength, showing that there was no ferromagnetic impurity.

It is well known that this liquid is highly associated at ordinary temperatures and, therefore, it was thought interesting to study the effect of temperature on this compound. Nitro-benzene and other heavily associated organic liquids have been studied by Dr. Rao and Varadachari,[1] Bhatnagar[2] and Fahlenbrach[3] and the results are not concordant. Dr. Rao has found no change in the susceptibility value, while others find a decrease.

The boiling point of this liquid being 207·8° C., I studied the susceptibility of this liquid, in the range of temperature 23° C. to 70° C. At every temperature, the readings were taken several times and the mean taken as the correct value. It was found that there is no temperature effect on the susceptibility. This is in agreement with Dr. Rao's results that the break-up of association does not produce any change in the susceptibility.

In conclusion, I wish to record my grateful indebtedness to Prof. B. Venkatesachar for valuable guidance and suggestions. My thanks are due to Mr. Sibaiya for useful discussion and criticism.

Ageing of Surface of Solutions.

THE effect of age of a surface on its surface tension has been investigated by several workers. They have all employed either methods involving the contact angle or those in which the surface itself would be highly disturbed (*e.g.*, drop weight method). A critical study of available methods revealed that the surface pressure technique developed by Langmuir and Adam is most suitable for studying the phenomenon. This technique has been used in the present work.

A freshly formed surface of M/500 solution of benzopurpurin is shown to exhibit a regular fall of surface tension with time.

Simultaneous with the decrease in surface tension, it has been found that a surface film is produced at the ageing surface as can be detected by pushing the barrier towards the float. If an overcrowding of the surface is effected by pushing the barrier, the surface exhibits an *increase* of surface tension with time. The force-area relations of a five-minute old surface of M/5000 solution of the dyestuff are given in Table I.

TABLE I.

Area in sq. cm.	Surface Pressure in dynes/cm.
420	0
85	1
58	2
42	4
39	6
38	10

The film appears to be more or less of the condensed type. About one-sixth of the ten-minute old surface has been found to be occupied by the dyestuff molecules. The observed rate of accumulation of the solute molecules is far less than the calculated collision frequency, the two values differing by a factor of 10^9. The adsorption appears to be of the activated type. The rate of accumulation is more than doubled for a rise of temperature by 20° The high temperature coefficient of the rate of accumulation is in accordance with the hypothesis of activation. These studies have been helpful in obtaining the potential energy curves in the neighbourhood of the interface. This technique gives a semi-quantitative method of determining the efficiency of a substance as a foam producer.

The results obtained so far have opened out some new lines of investigation. A detailed account of the work will shortly be published elsewhere.

Dehydrogenating Action of Sulphur Monoxide.

IN connection with the work on the mechanism of the chemical action of certain sulphur compounds, we have been studying the properties of sulphur monoxide. The oxide prepared according to the method of Schenk[1] was passed through dry liquid paraffin kept at a low temperature and found to yield hydrogen sulphide. Similar results were obtained when decalin was used for absorption. No hydrogen sulphide was obtained on absorbing the gas in tetrachlorethylene. Sulphur monoxide was found to be comparatively stable in tetrachlorethylene solutions. These solutions yielded hydrogen sulphide with liquid paraffin or decalin. Sulphur monoxide gave hydrogen sulphide readily on treatment with methyl alcohol and more slowly with ethyl alcohol. Using special micro-analytical methods we were able to show that during the production of hydrogen sulphide the methyl alcohol was converted to formaldehyde by the sulphur monoxide in terms of the following equation :

$$2\,SO + CH_3OH = H_2S + HCHO + SO_2.$$

The dehydrogenating action of sulphur monoxide can, in general, be expressed as follows :

$$RH_2 + 2\,SO = R + H_2S + SO_2.$$

The reaction can in some cases be possibly on the lines :

$$RH_2 + SO = RO + H_2S.$$

Further work is in progress.

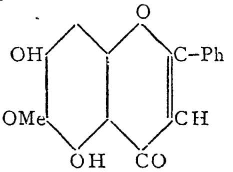
The Constitution of Oroxylin.

"OROXYLIN" (m.p. 225°), the yellow colouring matter, isolated by Naylor and Chaplin[1] from root bark of *Oroxylum indicum* Vent. was investigated by Naylor and Dyer[2] who assigned to it the formula $C_{19}H_{14}O_6$. These authors inferred the presence of three hydroxyl groups from the preparation of an acetyl derivative, assumed to be a triacetyl derivative from the amount of oroxylin recovered from it by hydrolysis. Hydrolysis with alkali gave benzoic acid, a neutral substance, giving colour reactions of phloroglucinol, and phthalic acid. Hydrolysis with dilute alkali is stated to give benzaldehyde. Absence of a methoxyl-group was shown by a negative result for methoxy-determination by Zeisel's method.

We have investigated "Oroxylin" (m.p. 231–32°) isolated from the same source. Our carbon and hydrogen values for oroxylin agree with those of Naylor and Dyer, and we have also definitely identified benzoic acid as one of the products of hydrolysis. In other respects, however, our results differ essentially from those of these authors. We find that it contains a methoxyl group and is a dihydroxy methoxy flavone—$C_{16}H_{12}O_5$, $[C_{15}H_7O_2(OH)_2, OCH_3]$, its actual constitution being (I), *viz.*, 5 : 7 dihydroxy-6-methoxy flavone. This conclusion is confirmed by the properties of nororoxylin (the demethylation product of oroxylin), its monomethyl ether, and its dimethyl ether, all of which agree closely with those recorded for Bargellini's 5 : 6 : 7-trihydroxy flavone[3] (the baicalein[4] of Shibata, Iwata and Nakamura), 6 : 7-dimethoxy-5-hydroxy flavone,[3] and 5 : 6 : 7 trimethoxy flavone[3,5] respectively. Oroxylin is thus shown to be the 6-methyl ether of baicalein.



I

According to previous workers, oroxylin dissolves in dilute alkali with a red colour, which rapidly changes to green. We have established that this is due to an impurity associated in a small quantity with oroxylin, and oroxylin freed from this impurity, is stable to dilute alkali in which it dissolves with a permanent deep yellow colour. The colour reaction of this impurity with alkali indicates that the impurity is baicalein, which probably occurs along with oroxylin.

A detailed account of this investigation will be shortly published elsewhere.

Germination of Leguminous Seeds and Urease Activity.

THE enhanced urease activity accompanying the germination of urease-containing seeds[1,2] may be due to (1) an increase in the absolute quantity of the enzyme, (2) an elaboration of activators or elimination of inhibitors and/or (3) a greater extractability of the enzyme. A series of experiments designed to test these possibilities was carried out in which the activities of the aqueous extracts of defatted powders were compared with those of the powders themselves.

0·1 g. of the powder or a quantity of the extract corresponding to 0·1 gm. of powder, was incubated for 30 minutes with 10 c.c. of a 1·0 per cent. solution of urea (in phosphate buffer of pH 6·9) at 30°·0 C. and the ammonia liberated was estimated by the aeration method. The results obtained are tabulated below.

TABLE I.

(*Urease Activity expressed in mgms. of Ammonia Nitrogen.*)

Seed Material	Extract		Powder–100 mesh	
	U.G.*	G.§	U.G.*	G.§
Dolichos biflorus, Linn.	2·4	8·7	8·5	9·0
Glycine hispida (Mœnch)	5·4	8·2	9·7	9·6
Cajanus indicus, Spreng.	5·7	8·2	8·1	8·5
Canavalia ensiformis, Dc.	19·1	27·3	26·1	28·1

*U.G. = Ungerminated.
§G. = Germinated.

The results show (1) that the activities of the germinated seed extracts are invariably greater than those of the ungerminated seed extracts, and (2) that in the case of powders, the differences between the activities of germinated and ungerminated seed materials are not marked. The activities of the powders represent the total urease content of the seed, as the enzyme is capable of acting on its substrate in the absorbed state.[3] Calculated on the basis of the activities of powders, the percentage of extractable urease is above 95 in the case of germinated seeds, and less than 70, in the case of the ungerminated seeds. Activators and paralysers, if present, will influence the activities of both extracts and powders equally.

These considerations lead to the conclusion that part of the urease exists in the seeds in an adsorbed and unextractable condition—*desmo*-urease, and that during the process of germination, it is converted into an extractable, *lyo*-form. Further work is necessary to characterise the two forms of urease.

Ascorbic Acid Oxidase from Drumstick, *Moringa pterygosperma*.

IT has been shown[1] that extracts from different plants exhibit great variations in the rate of oxidation of ascorbic acid. As resistance to oxidation was usually shown by extracts which contained reducing substances other than ascorbic acid, it was inferred that such substances exerted a protective action on the acid. An example of a material in which ascorbic acid was extremely stable to oxidation and which contained a large proportion of substances titrating against iodine but not against Tillmans' reagent, was the press juice of the Indian gooseberry, *Phyllanthus emblica*. In order to examine if this juice contained protective substances, it was decided to try the effect of its addition to the press juice of drumstick, *Moringa pterygosperma*, which on account of the identity of iodine and Tillmans' titres, was known to contain ascorbic acid as the only reducing substance. The surprising result was, however, obtained that, in contradistinction to trichloroacetic acid extracts of drumstick, its *press juice* did not reduce 2 : 6-dibromophenol-indophenol : further, that the juice rapidly oxidised the reducing factor in gooseberry or in orange juice, as also solutions of ascorbic acid (B.D.H.). It was also found that if the intact drumsticks were immersed in boiling water for a short time, press juice containing the usual amount of ascorbic acid could be obtained. Thus, in drumstick juice, the presence of an enzyme system capable of

oxidising ascorbic acid and which was inactivated either by boiling, or by treatment with trichloroacetic acid, was clearly indicated. Such a system, termed "hexoxidase" was shown to be present in cabbage juice by Szent-Györgyi in 1931.[2] Recently,[3] the isolation of an ascorbic acid oxidase from *Cucurbita maxima* was reported.

A preparation of the enzyme from drumstick was obtained as follows:—The press juice was centrifuged, the supernatant liquid treated with 5 per cent. ammonium sulphate (solid) and left in the ice-chest overnight. Next morning, the heavy precipitate that had formed was filtered off and the active filtrate further treated with ammonium sulphate to 35 per cent. final concentration (about 75 per cent. saturation). The resulting fine precipitate was separated by centrifuging, dispersed in a small volume of water (about a sixth of the original volume of press juice) and filtered. Thereby a clear yellow filtrate possessing very powerful oxidising action was obtained.

The action of the enzyme was studied with ascorbic acid as substrate at the optimum pH of 5·3 (9·75 ml. primary + 0·25 ml. secondary phosphates according to Sorensen) at 37° C. The amount of ascorbic acid present at any time in the reaction mixture was determined by titrating the latter against standard solution of 2:6-dibromophenol-indophenol. In a typical experiment, 0·1 ml. of the enzyme solution, obtained as above, was found to completely oxidise 0·4 mg. of ascorbic acid to its reversible oxidation product in 3 minutes in a total volume of 5 ml. From studies so far made of the kinetics, it appears that the reaction is monomolecular and the rate of oxidation is directly proportional to the quantity of enzyme and independent of substrate concentration.

At low concentrations of cyanide and H_2S (10^{-3} M) the enzyme is greatly inhibited, which thus differs from the enzymes obtained by Szent-Györgyi (*loc. cit.*) or Tauber and co-workers (*loc. cit.*).

Guaiacum, catechol, pyrogallol and *para*-phenylenediamine were not oxidised by the enzyme preparation except in the presence of H_2O_2. This peroxidase action exhibited by the preparation is, however, totally unconnected with the oxidative mechanism which does not require H_2O_2 for its action. That the ascorbic acid oxidase acts independently of the co-existing peroxidase was also shown by the complete disappearance of peroxidase activity in presence of 10^{-4} M cyanide, when the oxidising action was still very definite. Further, alcohol and acetone were found to destroy almost completely the ascorbic acid oxidising constituent, but left the peroxidase unaffected.

These results confirm the findings of Tauber *et al.*[3] that there exists in plants, apart from the complex mechanism postulated by Szent-Györgyi (*loc. cit.*) and by Szent-Györgyi and co-worker[4], a specific enzyme capable of oxidising ascorbic acid.

A New Apparatus for Carbonic Acid Estimations in Soils.

GASOMETRIC estimations of carbonic acid in soils are generally carried out with the apparatus designed by Collins. Although convenient for many purposes, Collins's Calcimeter suffers from certain inherent defects. The intervention of a rubber tubing between the reaction flask and the measuring burette may occasionally cause considerable errors. As one end of the tube adjacent to the measuring burette is open to the air, the instrument is very sensitive to atmospheric pressure fluctuations. To circumvent these difficulties, an apparatus for carbonic acid determinations has been developed in this Laboratory. This apparatus is independent of atmospheric pressure variations, and the use of a modified Thunberg[1] tube for the reaction makes it possible to mix the reactants very effectively. The apparatus can also be employed for the study of physiological functions provided the experiments are to be carried out at the room temperature.

The principle of the apparatus (Fig. 1) is the same as employed by the authors for another purpose.[2] The amount of CO_2 evolved will be proportional to the increase of pressure in the reaction bulb. If h is the increase of pressure in mm. of Brodie solution and x is the amount of CO_2 evolved in c.mm. at N.T.P. (dry), we have

$$x = h\left(\frac{V_g\frac{273}{T} + V_f a}{P_0} + A\frac{273}{T}\right),$$

where V_g = c.mm. gas in the bulb down to the "O" mark on the manometric tube,
V_f = c.mm. acid in reaction bulb,
a = Bunsen absorption coefficient of CO_2,
P_0 = pressure of one atmosphere expressed in mm. of Brodie solution,
A = area of cross-section of manometer tube in sq. mm.

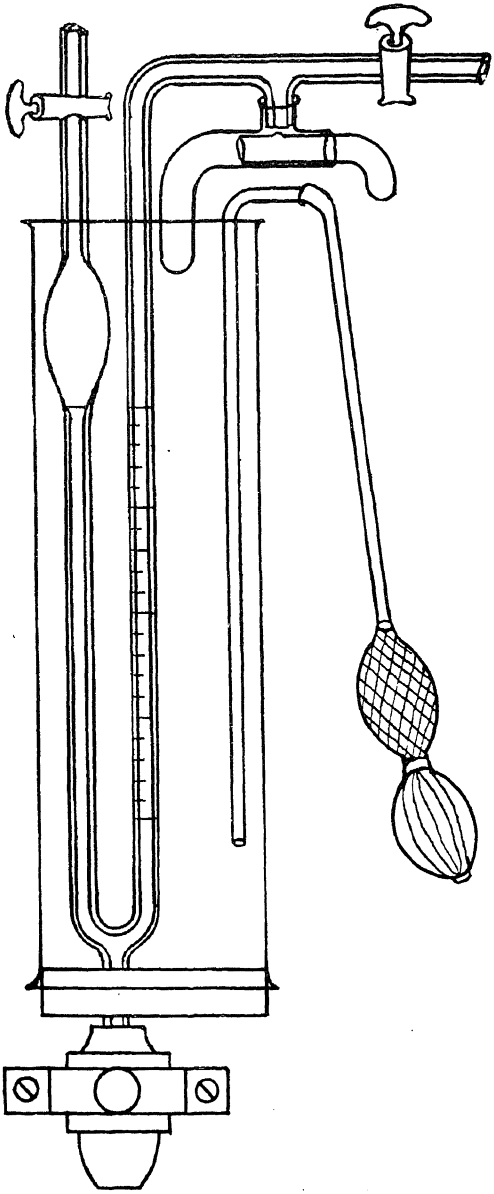

Fig. 1.

Having obtained the amount of carbon dioxide evolved in c.mm. at N.T.P. the percentage of carbon dioxide in the soil is easily computed. One c.mm. of carbon dioxide at N.T.P. weighs 0·001977 mgm., and the percentage by weight of carbon dioxide in the original sample, say x, is given by the following formula:

$$x = \frac{V \times 0 \cdot 1977}{w}$$

where V = volume of carbon dioxide in c.mm. at N.T.P.
w = weight of the sample in mgm.

The accuracy of the apparatus is ± 1·25 per cent. The various details as to construction, manipulation and computation will appear elsewhere.

Relative Wood Preservative Efficiency of the Tri- and Pentavalent Forms of Arsenic.

ALTHOUGH it has been unanimously accepted that arsenic, in all its forms, is highly toxic and is an efficient wood preservative, there has been considerable divergence of opinion on the question of the relative wood preserving efficiency of tri- and pentavalent compounds of arsenic. For example, Kunkel[1] mentions that pentavalent arsenic is less poisonous than trivalent arsenic.

The writer has had for over 42 months several test specimens of wood, of 12 species, that were treated with two different concentrations 1½ per cent. and 2½ per cent. in aqueous solution of As_2O_3 and of As_2O_5. The specimens were 24″ long, 2″ × 2″ in cross-section. They were impregnated under identical conditions of pressure (in the cold) with the above solutions. The treated pieces were allowed to air-dry, and then laid down in the antiseptic test-yard of the Forest Research Institute, Dehra Dun. The average annual rainfall in the region of the test is about 80 to 100 inches. In the case of the specimens treated with 2·5 per cent. of As_2O_3 and of As_2O_5, there is practically no difference in the present condition of the test pieces. 7 out of 12 have been destroyed in each case. One has been moderately white-ant and fungus attacked, and the rest

have been slightly fungus attacked. All the 12 untreated controls have been destroyed within 42 months.

As regards specimens treated with 1·5 per cent. of As_2O_3 and As_2O_5, the results are slightly in favour of the latter.

In view of the above, and despite the much greater tendency of As_2O_5 (as compared to As_2O_3) to leach out of wood, it would appear that the wood-preserving efficiency of As_2O_5 against termites and fungi is not inferior to that of As_2O_3.

Tuberculation of Water Pipes.

THE views held by different investigators with regard to the formation of tubercles in pipes are rather conflicting. Most of the earlier workers[1] consider that the tubercles are simple chemical precipitations. A few of them have also suggested that iron organisms like *Leptothrix*, *Gallionella*, *Cladothrix*, *Crenothrix*, and *Spirophyllium*, when present, play only a very subordinate or secondary rôle in the formation of these nodular excrescences. Other authors[2] have stated that tubercular incrustations are solely due to the abstraction of iron by *Gallionella*, *Leptothrix* and *Spirophyllium*. It also appears that many of the earlier workers have confused the slow appearance and steady development of the tubercles or "limpet" like structures with the sudden visitations[3] of the filamentous forms like *Crenothrix* and *Cladothrix* that occasionally occur in water reservoirs and conduit pipes. The persistence of tubercles inside the pipe, in spite of the incessant flow of water through it, has not been adequately explained.

With a view to studying the relation between the tubercle and the surrounding water in the pipe, a detailed chemical and bacteriological analysis of some of the tubercles was carried out as also a set of samples of water taken from different parts of a town supply system.

TABLE I.

Chemical Composition of Tubercles in Cast Iron Pipes.*

Constituent	Percentages on dry weight							
	Samples							
	I	II	III	IV	V	VI	VII	VIII
Iron (Ferrous as FeO)	3·7	4·6	3·1	2·1	6·7	6·4	8·2	2·4
Iron (Ferric as Fe_2O_3)	69·5	68·5	68·7	65·0	67·9	70·7	72·0	66·0
Aluminium (as Al_2O_3)	7·6	8·2	9·8	12·1	6·2	8·0	7·5	12·7
Silica	6·0	5·7	3·1	3·3	6·6	5·9	3·9	3·4
Phosphoric acid (as P_2O_5)	0·2	0·1	0·4	0·4	0·1	0·3	0·2	0·3
Manganese (as MnO_2) .. .	0·2	0·1	0·2	0·4	0·6	0·2	0·2	0·7
Calcium (as CaO)	1·3	1·4	0·8	0·7	1·8	0.9	0·6	0·7
Magnesium (as MgO)				Tra	ces			
Total nitrogen	0·05	0·05	0·14	0·20	0·09	0·11	0·08	0·15
Total carbon	1·96	1·65	3·57	5·28	1·21	1·22	1·06	2·20
Loss on ignition	8·8	8·4	12·8	11·5	9·2	8·7	9·2	11·7
Moisture content	15·57	17·44	6·83	36·79	29·48	34·87	37·56	3·93

I. Collected from dead end of the main containing filtered and chlorinated water for washing the filter units.

II. Similar to I, but collected from a different end.

III. Collected from the leading main to the General Hospital.

IV. Collected from a hatch box in the 9″ water main carrying filtered water.

V. Collected from a hatch box in the 30″ water main carrying raw river water.

VI & VII. Similar to V, but collected from different portions of the water main.

VIII. Collected from an old pipe which was cut out from the Distribution System from near the Power House. The main is 8″ in diameter.

* The samples were obtained through the courtesy of the Water Works Engineer, Trivandrum (South India) to whom the author's thanks are due.

TABLE II.

Chemical Analysis of Samples of Water from Different Parts of the System.

Sample	Parts per 100,000				
	P_H	Total Solids	Loss on Ignition	Iron	Aluminium
I	6·9	35·80	31·60	0·102	Traces
II	7·8	14·80	6·05	0·099	do.
III	7·5	11·40	7·60	0·150	do.
IV	7·5	8·50	5·12	0·165	do.

I. Raw river water, *i.e.*, the source of water supply (Trivandrum Water Supply).

II. Water of the same sort as Sample No. I, but treated with lime and allowed to settle for about 8 hrs.

III. The same water that has been filtered but not chlorinated.

IV. The same water filtered and chlorinated: representative sample of the street tap water collected from a tap about 2½ miles away from the Filter House.

From the foregoing tables, it will be observed (1) the tubercles collected from the particular system are more or less similar in their chemical composition; (2) iron in the ferric condition is the chief constituent, while, aluminium, silica, ferrous iron, calcium, magnesium, manganese, and phosphate are present in much smaller proportions: organic carbon and nitrogen are also present in small quantities; (3) the iron necessary for the formation of the tubercle comes mostly from the pipe itself, while the water passing through the pipe system supplies the other constituents. It is more than likely that a large proportion of the silica, phosphorus, manganese, and carbon is derived from the pipe, for, cast iron contains these in appreciable quantities; (4) there is a slight, but apparently progressive increase in the content of the water, as the water passes through the pipe. This would show: (*a*) iron from the pipe passes into solution in the water and (*b*) the iron of the tubercle does not therefore appear to be from the water but is mainly derived from the pipe itself; (5) the tubercles examined contain none of the better known iron bacteria,[4] but they are invariably associated with a lower form of fluorescent bacillus of the *pseudomonas* type which is derived from the water.

Direct experiments carried out with pieces of cast iron pipes, with and without a protective covering, show that tubercles appear at points bare of the coating already exposed or where as often happens the protective coating has been removed by the flow of water. A coating of tar or asphalt *does offer* some protection but that would appear to be only temporary. Even small pin points in the coating through which the iron is exposed are sufficient to start rusting which will soon be followed by tuberculation. Rusty layers do not, however, assume any definite proportions. They can be and are often partially flushed out by a vigorous stream of water. Tubercles, on the other hand, have definite conical or dome-like shapes, grow out prominently and persist even when a strong current of water is flowing through the pipes. This remarkable behaviour would appear to bear some relation to the occurrence of the *pseudomonas* which flourishes in the rusty layers and probably helps to cement them together so as to produce ultimately the characteristic tubercular structure studied by us.

The most interesting feature about this bacterium is its ability to live and grow in rust; by repeated sub-cultures in media containing pieces of metallic iron, pure strains of the organism could be easily isolated. Rusting of only a moderate nature is observed when filtered and chlorinated water is passed through the pipes. If, on the other hand, either ordinary filtered water or sterile water artificially infected with the specific organism is circulated, the rate of rusting is increased, tuberculation also sets in rapidly and in a few weeks the entire inner surface of the pipe is found dotted with incrustations.

Further work is in progress with a view to (1) identifying the associated organism and studying its physiology and the precise manner in which it contributes to the formation and persistence of tubercles, and (2) devising improved methods for providing the interior of pipes with protective coating which would resist rusting and subsequent formation of tubercles.

The author wishes to thank Prof. V. Subrahmanyan for his keen interest in the work.

Chromosome Numbers in Safflower—*Carathamus tinctorius*, Linn.

GREGORY, P. J. (1935)[1] has reported from the study of the somatic mitosis the $2n$ number in Safflower as 20. The authors of the note who worked with Pusa type 24 made several counts in metaphase plates of somatic and meiotic mitoses. These revealed 24 chromosomes for $2n$ and 12 bivalents for n respectively.

[1] *Proc. Ind. Acad. Sci.*, 1935, **1**, No. 11.

WITH reference to the above note regarding the chromosome numbers in Safflower (Pusa Type 24), I would like to report on the results so far derived in my present investigation of the chromosome studies of the different Pusa types of Safflower. Of these, I have so far been able to ascertain the chromosome numbers in two Pusa types (Types 1 and 27), both of which gave the $2n$ number of chromosomes as 24. So, it is fairly certain that the chromosome numbers in Pusa types of Safflower is $2n = 24$. In this connection I would like to add that the varieties I have investigated and published in my previous paper on Safflower (Gregory, P. J., 1935),[1] were distinctly the Coimbatore types and as far as the somatic counts were concerned, the $2n$ number was 20 in those cases. It may be that the variation in chromosome numbers noted above is due to a varietal difference between the Coimbatore and Pusa types of Safflower. Only further investigation, which is now proceeding, can clearly explain the exact cause of this variation.

On Some Abnormal Flowers of *Hibiscus Rosa-sinensis*.

IN October 1933 the author collected a number of abnormal flowers from some plants in a private garden in Sagar, Mysore State. The owner of the garden had grown them from cuttings he had brought from some place on the West Coast.[1] All the flowers borne on these plants were abnormal.

Abnormality is seen in the three inner whorls, the corolla, the andrœceum and the gynœceum. The calyx is normal, with five

Fig. 1. L. S. of flower.

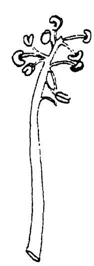

Fig. 2. A Stamen.

lobes; and the epicalyx consists of seven lobes.

The phenomenon known as *positive dédoublement*[2] is seen in the corolla, which consists of five whorls of petals, twenty-seven in all being seen in the transverse section shown in Fig. 3. The outermost whorl has the typical twisted æstivation, the second interpenetrates with the first, and the inner petals are folded in a complicated manner.

The normally monadelphous staminal tube (which is theoretically believed to be composed of five fused epipetalous members)[3] has split up into six stamens so that even here there is an increase in number. Each of these six stamens bears an indefinite number of one-celled anthers on connectives (Figs. 1 and 2). This splitting up of the staminal tube known as *Dialysis*[4] has been recorded in Hollyhock (*Althœa rosea*).

The ovary is also abnormal, the carpels having been converted into petaloid structures. This type of metamorphosis has been termed *petalody*.[5]

This combination of the three abovementioned abnormalities in *H. Rosa-sinensis* is interesting and has not been recorded before,[6] although this species has been known to show diverse kinds of abnormalities. These phenomena are generally regarded as reversionary.

A Preliminary Note on the Development of the Female Gametophyte in *Costus speciosus* L.

IN a recent article Maheshwari[1] has reviewed the work on the embryology of angiosperms that has been done in India and suggested a re-investigation of certain genera including Costus. Previous investigation on this line on *Costus speciosus* L. was carried out by Humphrey[2] who suggested a "Lilium type" of embryo-sac development.

The results of our investigation show that an archesporial cell is developed in the hypodermal layer of the nucellus, it cuts off a parietal cell and then functions as the megaspore mother-cell. The megaspore mother-cell increases in size before division. In the stages of the heterotypic prophase the nucleus, in some preparations, is observed to lie at the lower end of the protoplast (Fig. 1). The heterotypic spindle, however,

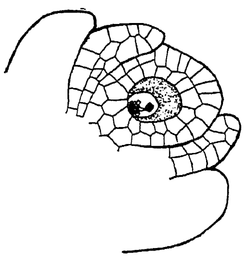

Fig. 1. × 375.

is oriented centrally and is quite sharp. A cell plate is noted on the completion of the reduction division. The homotypic spindles are arranged somewhat obliquely and as a result four obliquely-oriented tetrad of macrospores is formed (Fig. 2). The chalazal

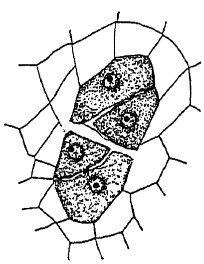

Fig. 2. × 250.

macrospore alone functions while the rest degenerate. The mature embryo-sac is eight-nucleate and is of the normal angiospermic type. The antipodals later degenerate.

The development of the embryo and the endosperm is being worked out and some interesting stages in the development of the endosperm have been obtained. A detailed account of the complete investigation will be published elsewhere in due course.

On an Abnormal Flower of *Convolvulus pluricaulis* Chois.

ONE of the flowers of *Convolvulus pluricaulis* Chois. (= *Evolvulus pilosus* Roxb.)[1] examined during a practical class showed an apparently fertile anther attached to one of the two stigmatic branches of the style (Fig. 1).

Fig. 1. × 4.

The anther is practically sessile and of the same shape and size as the other anthers of the flower. Though it had dehisced like the others, there were just two pollen grains inside and these were exactly like the normal pollen grains; the anther was obviously fertile. Serial sections of the specimen showed no suggestive differences in the internal structures of the two stigmatic branches.

Parts of the pistil being substituted by or transformed into anthers are on record and described under "Staminody of the Pistil".[2] Anthers surmounting the pistil have also been noted in a few plants.[3] Worsdell[4] records the case of an abnormal flower of *Linaria vulgaris* where, in addition to other

abnormalities, imperfect anthers were borne on the style. Baillon's[5] description of "stigmas of *Ricinus communis* as having been in one instance antheriferous" furnishes another close parallel. All the above cases are supposed to be examples of Metamorphosis. On the other hand, adhesion of carpelloid or even untransformed stamens to pistils is quite common and is described under the category of Adnation.[6]

I am inclined to consider the specimen under consideration as an example of the latter category. So far as I know this abnormality has not been recorded in the family Convolvulaceæ.

My best thanks are due to Mr. O. N. Tyagi of the First Year B.Sc. Class who drew my attention to this exceptional flower.

The Kaldurga Conglomerates and the Iron Ore Series of the Bababudans, Kadur District, Mysore.*

REFERRING to the recent papers on the Bababudan rocks published by Mr. C. S. Pichamuthu,[1] I should like to offer a few remarks regarding the Kaldurga conglomerates and the Iron ore series of rocks.

The Kaldurga conglomerates were originally considered to be sediments by Bruce Foote,[2] Wetherell[3] and Smeeth,[4] but as a result of later examination Slater[5] and Smeeth[6] doubted the sedimentary origin. Subsequently, Sampat Iyengar[7] mapped the region in great detail and came to the conclusion that they were of autoclastic origin. Whether these rocks can finally be proved to be sediments or not, is difficult to say at present, but a critical examination of some of the arguments put forward by Pichamuthu shows that more than one opinion is still possible on the subject, and the evidences he has adduced are not sufficiently strong and convincing to accept a sedimentary origin for all these formations.

Many of the features such as the shape and rounding of the pebbles, sharp boundary between pebble and matrix, varied assemblage of pebbles, the difference between pebble and matrix and alternation of pebbly and non-pebbly bands, etc., are not entirely wanting in conglomerates which could be shown to be of autoclastic origin. Pichamuthu's argument[8] that the granite pebbles do not contain orthoclase or microcline (implying thereby that the intrusive Tarikere granite is not represented as pebbles in the conglomerates) appears to be based on insufficient examination. Sampat Iyengar laid much emphasis[9] on the similarity between the granite of the conglomerate and the Tarikere gneissic granite. A re-examination of the material collected by him bears out his conclusions. In the granite pebbles collected by him from the temple boulder[10] (Z_4/869, 866, etc) both orthoclase and microcline are found, though only to a limited extent. When the granite is subjected to crushing and shearing, it is only natural to expect an alteration of the felspars, the albite remaining over as the more stable under metamorphic conditions whereas orthoclase would get converted into sericite and muscovite. Sericite is no doubt found largely in the granitic pebbles and they might have been formed from the alteration of the potash felspars.

B. Rama Rao, in the course of his detailed examination of the Shimoga Belt during the last field season, has obtained many distinct evidences of ripple marks, current bedding, rain prints and other undoubted indications of sedimentation in the quartzites and some of the conglomerates of that region. It may be probable that even the Kaldurga conglomerate has had a sedimentary origin, but the evidences adduced by Pichamuthu are not strong enough to warrant such an assumption. Moreover, the evidences for shear and crushing are clearly indicated and it remains yet to be proved if this has taken place in a pure sedimentary conglomerate, or in a complex of igneous rocks, or even in a mixed series of igneous rocks and sediments. The evidences now available, however, do not justify a hasty conclusion and the inference that the Tarikere granite has played no part in the formation of the "Granite Pebbles" of the Kaldurga conglomerates is unwarranted. The question of the precise mode of origin of these rocks

* Published with the permission of the Director, Mysore Geological Department.

merits a considerably more detailed investigation from various aspects than what has been done at present.

The geological section[11] drawn across the Kaldurga conglomerate represents a syncline near the Kaldurga hill and an overfold near the Nandi-Hosahalli valley. The map, however, indicates only the direction of the dips in some places and their magnitude is not known. Sampat Iyengar's original map shows that the dips are not consistent over any large area, particularly in the eastern band, though the general trend in the western bands is eastwards and that of the masses to the south of Nandi is north to north-north-eastwards. In the absence of a systematic mapping of the formations into definite beds, the interpretation of the precise tectonic features becomes very difficult. While the synclinal structure yet remains somewhat doubtful, the overfold need not be assumed at all. The separation of the schists may have taken place by stoping away of a portion of the tilted general succession by the intrusive granite exposed in the Nandi-Hosahalli valley.

The problem of the ferruginous quartzites again confronts us with many difficulties and the arguments of Pichamuthu offer no conclusive proof either, of a sedimentary origin. For instance, the dominance of MgO over CaO together with that of Fe_2O_3 over FeO has been claimed to be a positive indication[12] but one may as well argue, from the same analyses, that the dominance of Na_2O over K_2O, if taken into consideration, does not support such a contention.[13] It has been assumed that the sediments were derived from spilitic rocks, but these have neither been mapped nor shown to exist in any large masses. Judging from the descriptions,[14] they are only of a local development and do not appear to be very different from the Lingadhalli and Santaveri Traps. The chemical analyses of these latter, however, do not show any large percentage of Na_2O and the assumption of a spilitic suite requires yet to be proved.

The occurrence of "interformational folding" has been claimed to be noted in the ferruginous quartzite and taken to be a very good proof of sedimentation.[15] It is doubtful if these bandings can be taken to be true bedding or deposition planes. Bandings are noted to have originated in several ways and in these rocks metamorphism has obviously played a great part in producing many structural and mineralogical changes. Pichamuthu himself notes as one of the effects of igneous intrusion[16] "the banding of the rocks have been emphasised and the iron stones in the neighbourhood recrystallised." Anyway, it is difficult to place much reliance on a few isolated structural peculiarities and accept them as definite proof of sedimentary origin.

The finding of the Fossilwood[17] in the Iron ores is very interesting, particularly in view of the fact that these rocks have formed under conditions totally different to those that gave rise to the banded ferruginous quartzites. Until more material and information are obtained, we can draw no satisfactory conclusions.

That Bababudanite is of secondary origin and not an original constituent of the amphibolites was pointed out by Jayaram[18] as far back as 1923. He then opined that the amphiboles were derived from the alteration of impure calcareous grits and tuffs. Apparently, Pichamuthu also shares with Jayaram the view regarding the secondary character of bababudanite, but the precise mode of development of this mineral yet remains a doubtful point. In an earlier communication Pichamuthu and M. R. Srinivasa Rao[19] suggested that the amphiboles have developed at the intrusive contacts of the traps with the iron ore rocks and that they had little or nothing to do with the origin of the latter. But this view has been subsequently modified. Pichamuthu[20] now regards the bababudanite-magnetite schists as due to metamorphic differentiation of sediments derived from the spilitic rocks. As already remarked, the existence of spilites has not been proved, though it appears likely we have, in this region, some keratophyres and soda felsites (Galipuje Felsite). But, the relationship of these with the banded iron ore series is not definitely known.

Regarding the age relationship between the Tarikere and the Bababudan series, Pichamuthu agreeing with the inferences of Smeeth and Sampat Iyengar states that "the Tarikere series is younger than the Bababudan series not because of its intrusive character, but considering the stratigraphic sequence".[21] But the original maps reproduced in his papers with slight modifications do not lend support to this inference. The Kaldurga conglomerate does not appear to be a basal formation and whether the Tarikere and Bababudan series are marked by any unconformity or not is unknown and much more detailed work will be necessary

before we can come to any definite conclusion on these and other controversial points.

I HAVE read through the remarks offered by Mr. M. B. Ramachandra Rao on the results of my work on some of the rocks of the Shimoga Schist Belt, and I am afraid that many of these remarks are based on a rather superficial reading of my papers. It is after more than five years of field and laboratory investigation that I have come to the conclusion that the conglomerates, quartzites and banded ferruginous quartzites of this area are possibly sedimentary in origin, and I do not think that I can reasonably be accused of either basing my observations on "insufficient examination" or being "hasty" in my conclusions.

I am perfectly aware that "many of the features such as the shape and rounding of the pebbles, sharp boundary between pebble and matrix, varied assemblage of pebbles, the difference between pebbles and matrix, and alternation of pebbly and non-pebbly bands, etc., are not entirely wanting in conglomerates which could be shown to be of autoclastic origin." But it is the cumulative effect of all these and other characters found in one particular bed, that I consider more important. I am not as sure as Rao, however, that a varied assemblage of pebbles can be present in an autoclastic conglomerate; certainly not, at any rate, the great variety that I have noticed and described in the Kaldurga conglomerates.[1]

Further, he states "Pichamuthu's argument that the granite pebbles do not contain orthoclase or microcline.... appears to be based on insufficient examination." Rao is obviously not aware that by the courtesy of the Director of the Mysore Geological Department, I had an opportunity of examining not only the particular slides he refers to (Z_4/869, 866) but also several others, and I am sure I have found no microcline or orthoclase. There is, no doubt, a little muscovite in the granite pebbles, but not enough to suggest that all the original potash-felspars were converted into this mineral.

I am particularly pleased to read from Rao's remarks that evidences of sedimentary origin of some of the rocks of the Shimoga Schist Belt have recently been obtained by B. Rama Rao. These discoveries strengthen my contention that some of these rocks have had a sedimentary origin. I would like to point out, however, that it is not quite fair to characterise my views arrived at after a detailed study of the various aspects of these rocks as "hasty" or "unwarranted" while according to Rao, ripple marks, current bedding and even "rain prints" recorded by Rama Rao in these metamorphosed rocks are "undoubted evidences of sedimentation"!

With reference to the tectonics of the area, the V-shaped outcrops of beds surrounding Nandi village,[2] indicate a pitching fold. Rao criticises me for "assuming" an overfold here, but himself proceeds to *assume* that the structure might have been caused by the intrusion of the granite.

Regarding the banded ferruginous quartzites, the great dominance of magnesia over lime has been considered both in the Lake Superior Region[3] and in Singhbhum[4] as evidence of sedimentation and in support of my conclusions, I have only followed this line of argument and have drawn attention to the similar relationships existing in the Bababudans.

In regard to the occurrence of spilitic rocks, it will be seen from a paper of mine to be shortly published elsewhere, that there is in this area, a soda-rich series of rocks

comprising albite granites, albite syenites, keratophyres, soda felsites, oligoclase dolerites, albite basalts, albitites and albite schists, and that the distribution of these rocks is not quite so "local" as Rao seems to think. Is it far-fetched to suggest that sediments derived from such a terraine would be rich in soda?

Rao would have it that metamorphism has been the cause of banding exhibited by the ferruginous quartzites. In *support* of this he quotes me and says "Pichamuthu himself notes as one of the effects of igneous intrusion 'the banding of the rocks have been emphasised and the ironstones in the neighbourhood recrystallised'." Rao has missed the significance of the word "emphasised" used by me; it obviously implies that the bandings were there before they were metamorphosed and that they were subsequently enhanced by metamorphism.

To any one who has not read my papers, Rao's statement, "that bababudanite is of secondary origin and not an original constituent of the amphibolites was pointed out by Jayaram as far back as 1923," might convey the impression that I was not aware of this. I have referred in one of my papers[5] to Jayaram's views who considered "that the occurrence of this mineral is precisely comparable to that of tourmaline in the altered acidic rocks of the Champion gneiss series". The other officers of the Mysore Geological Department did not, however, share with Jayaram in this view. My colleague, M. R. Srinivasa Rao, and I were the first to point out that the mineral was developed as a result of thermal metamorphism.[6] I am frankly surprised at Rao suggesting that I have now changed my views regarding the origin of this mineral in the schists. I have done no such thing. That I still adhere to the view that bababudanite has always originated due to contact metamorphism, becomes clear on page 30 of my paper on "The Iron Formations and Associated Rocks of the Eastern Bababudans" where I say "they (the bababudanite-magnetite schists) are formed by the thermal metamorphism of certain of the original layers in the ironstones"; also on page 37, where I have said, "like the mineral bababudanite, these amphibole magnetite schists have also originated as the result of contact metamorphism".

With reference to the age relationship between the Tarikere and the Bababudan Series, I have nowhere suggested that the Kaldurga conglomerate is a basal formation. When I say that "The Tarikere Series is younger than the Bababudan Series, not because of its intrusive character, but considering the stratigraphical sequence," I do not imply a stratigraphic break between the two Series. All that I mean is that the rocks belonging to the so-called Tarikere Series (mainly the conglomerates) overlie those which are supposed to belong to the Bababudan Series (the iron formation, etc.).

Pungency in Chillies (*Capsicum annuum*): A Mendelian Character.

IN a letter to *Current Science*[1] under the above title, K. Ramiah and M. R. Pillai state as follows:—

> "The inheritance of a large number of characters in chillies has been studied by Deshpande (1933) but we have not come across any reference to the inheritance of pungency. It has therefore been considered that information given below with regard to this character will be of interest."

The inheritance of pungency has been studied by me and the results were reported in the *Scientific Reports*, Imperial Institute of Agricultural Research, Pusa, 1930–31, p. 37 and published in the *Indian Journal of Agricultural Science*, Vol. V, No. IV, Aug. 1935, 513–16. Both the references have evidently been overlooked by the authors. Their results, however, agree with mine in so far as the F_1 and F_2 generations are concerned.

Moisture Variation Indices of Soils in Relation to their other Physical Properties.*

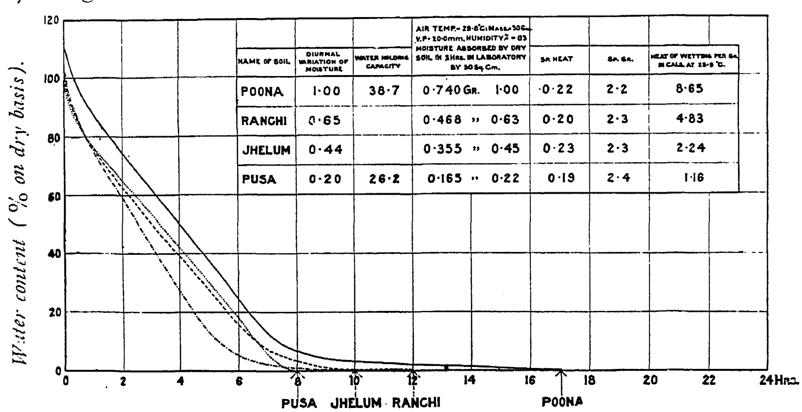
By M. S. Katti, B.Sc.
(*Research Student, Meteorological Office, Poona.*)

In two recent papers[1,2] it was shown that during the clear season when the surface soil contains only hygroscopic moisture, there is a regular diurnal exchange of moisture between the soil and the air. Later,[3] it was observed that this variation of moisture content in the soil is a definite characteristic or "index" of that soil. It is interesting to study the "moisture-variation-index" in relation to other important physical properties of the soil (see Fig.).

The sequence of the moisture variation indices of different soils as observed in the open is practically the same as that of their power to absorb water vapour when exposed under known conditions of temperature and humidity in the laboratory. The water-holding capacities of a few soils (expressed on air-dry basis) are given below :—

The values of the heat of wetting at 25·9° C. for different soils run parallel to those of moisture-variation-index, being large for the black cotton soils and small for the alluvial soils.

In determining the moisture content of a soil, the sample is usually kept in the steam oven "till the weight becomes constant". An exact study of the rate of drying in a steam oven is very instructive. The weight-time curves (see Fig.) for four typical soils starting with about 100% water (on dry basis) not only show the time for complete drying but also the rate of drying at different moisture contents. The times taken by different soils for attaining a steady minimum weight at 100° C. are in the same order as their moisture-variation-indices.



NAME OF SOIL	DIURNAL VARIATION OF MOISTURE	WATER HOLDING CAPACITY	AIR TEMP.- 29·8°C; MASS- 30 GM. V.P.- 20·0mm, HUMIDITY % - 83 MOISTURE ABSORBED BY DRY SOIL IN 3 HRS. IN LABORATORY BY 30 Sq. Cm.		SP. HEAT	SP. GR.	HEAT OF WETTING PER GM. IN CALS. AT 25·9 °C.
POONA	1·00	38·7	0·740 GR.	1·00	·0·22	2·2	8·65
RANCHI	0·65		0·468 ,,	0·63	0·20	2·3	4·83
JHELUM	0·44		0·355 ,,	0·45	0·23	2·3	2·24
PUSA	0·20	26·2	0·165 ,,	0·22	0·19	2·4	1·16

Time in hours.

Soil			Water-holding capacity
Poona	..	..	38·7 %
Sholapur	..	..	40·9 ,,
Hagari	..	..	30·9 ,,
Bangalore	..	..	24·0 ,,
Pusa	..	..	26·2 ,,
Lyallpur	..	..	22·8 ,,

The black cotton group of soils is able to retain 15% more of water than the alluvial group.

The similarity in the behaviour of a number of physical properties of different soils to their moisture-variation-indices is striking.

The above work was done under the guidance of Dr. L. A. Ramdas, Agricultural Meteorologist, Poona.

Obituary.

Henry Fairfield Osborn (1857-1935).

THE sad death of Henry Fairfield Osborn, Zoologist, Palæontologist, Educationist, Author and Administrator, at the age of 78, has created a gap among the American men of Science which it would be hard to fill. President Osborn—as he was generally known in America since he became the President of the Board of Trustees of the American Museum of Natural History in 1903 after the death of President Jesup—made very valuable contributions to the sciences of Zoology, Palæontology and Biology; a great deal of his Zoological and Palæontological work was essentially biological, in that it contributed to an understanding of the nature, continuance and evolution of life. In addition, his services to the cause of Education and his work as an administrator and author, are so remarkable that any of them would have won him an outstanding place amongst the leading workers of the times. Osborn was born on the 8th of August 1857. His father, William Henry Osborn, was a Founder and for many years President of the Illinois Central Railroad, and from him apparently young Osborn inherited his great administrative talents. He was educated in the Columbia Grammar School and Lyons Collegiate Institute of the New York City, and later graduated at Princeton College where he was strongly influenced by the teachings of the well-known Geologist Professor Arnold Guyot. Taking up practical field work in the Museum of Geology and Archæology at Princeton soon after his graduation, he became the leader of the palæontological section of the University Expeditions to Colorado and Wyoming in 1877 and 1878. In 1878–79 he took courses in Anatomy and Histology at the College of Physicians and Surgeons in New York, and in 1879–80 went to Europe, where he studied Embryology at Cambridge under Professor Francis Balfour and Comparative Anatomy in London under Professor Thomas Henry Huxley. He later spent some time at Coburg, Germany, learning German. In 1881 he was appointed as the Assistant Professor of Natural Science at Princeton, and in 1883 as the Professor of Comparative Anatomy; this latter post he held till 1890. In 1891 he was invited to occupy the Da Costa Chair of Biology of the Columbia University for organising the Zoological Department of the University. He selected the first officers of the department and was responsible for the planning of the teaching and research work in Zoology in this institution. During this period he started the well-known Columbia Biological series of publications and was also responsible for the starting of a University Press at Columbia which has done such useful work in the cause of education. From 1892–95 he served as the Dean of the Faculty of Pure Science of the University. In 1910 he retired from active teaching at Columbia, but up to his death retained his connection with the University as the Research Professor of Zoology.

Henry Fairfield Osborn.

From 1891–1910 Professor Osborn, in addition, carried on active work as the Curator of the Department of Vertebrate Palæontology at the American Museum of Natural History. In 1910 he retired from the Curatorship of this section, but he continued to act as the Curator-in-chief not only of this division but also of the divisions of Mineralogy, Geology, Geography and Astronomy. In addition to being a trustee

of the American Museum of Natural History, he served as its Vice-President (1899–1901) and was its President from 1908 to the date of his death. During his Presidential administration he inaugurated a highly efficient plan for the internal organisation of the American Museum, and established its well-known series of publications of which the *Natural History* is a popular publication well known all over the world. During the period of his administration there has been a remarkable advance in the palæontological technique of the Museum, while the most important development for the instruction and recreation of the visiting non-scientific public has been the preparation and installation of attractive museum groups in replicas of their natural surroundings in almost all sections of the Museum. As a result of his incessant propaganda work he was able to raise sufficient funds for sending numerous expeditions in search of fossil vertebrates and for the collection of natural history material not only to different parts of America but almost all over the world. It was his far-seeing policy that has made the American Museum of Natural History one of the biggest institutions of its kind, with its very rich study collections for research, and the beautiful and instructive exhibits in its very extensive public show galleries. Such galleries as the Hall of Life of the Oceans, the African Hall of Mammals, the Asiatic Hall of Mammals, the wonderful groups of birds from different parts of the American continent, the marvellous restorations of fossil animals from different parts of the world, the groups illustrating the life and habits of the American Indians from different parts of the American continents contain beautifully arranged exhibits of high educative value. His work in the cause of public education was considered of so great an importance as to be acknowledged by the award of the Roosevelt Medal of Honour, presented by President Harding in 1923.

In 1900 President Osborn was appointed as the Vertebrate Palæontologist of the U.S. Geological Survey, and in 1924 he was promoted to the rank of its Senior Geologist. In 1903 he was unanimously elected as the Secretary of the Smithsonian Institution, the highest scientific post in the United States of America, but in view of his great interest in the American Museum of Natural History he declined this high honour.

His first scientific contribution was published at the age of 21, and since that date during the 58 years of his active life he published an enormous number of original contributions either in the form of papers and monographs or as separate volumes dealing with special subjects. Of these, special mention may be made of his outstanding monograph on *The Titanotheres of Ancient Wyoming, Dakota, and Nebraska* (1929), his monograph on the *Fossil Proboscidæ* (1932), *From the Greeks to Darwin* (1894), *The Age of Mammals* (1911), *Origin and Evolution of Life* (1917) and *Men of the Old Stone Age, their Environment, Life and Art* (1918).

His earlier work was devoted to studies on the evolution of mammalian teeth, as a result of which he prepared a descriptive nomenclature which has replaced the conflicting and confusing terminology of previous investigators and resulted in his theory of "determinate variations" in the evolution of organisms, which he called the "doctrine of rectigradation"; this is not to be confused either with the "orthogenesis" of Eimer, or with the "mutations" of de Vries. The same principle of hereditary ancestral control of variations he afterwards found illustrated by the origin and evolution of horns and other organs of vertebrates. His principles of adaptation were "neither theories nor hypotheses but facts clearly and repeatedly revealed by palæontological research," and these, according to Osborn, help to solve the riddle of the bio-mechanical origin of species. As a result of his detailed studies of the causes of evolution he enunciated his new principle of "tetraplasy" which he believed to be fundamental for the evolution of organisms. This principle of tetraplasy or "the law of the four inseparable factors of evolution" (1912) was formulated as follows: "The life and evolution of organisms continuously centre round the processes which we term heredity, ontogeny, environment and selection. These have been inseparable and interacting from the beginning. A change introduced or initiated through any one of these factors causes a change in all."

Amongst his Zoological contributions, reference may be made to his papers dealing with the "Brain of Amphiuma," the "Brain of Menopoma" and the "Internal Structure of the Amphibian Brain" (1883–1888). This work resulted in his detailed "Studies on the Brains of Amphibians, Reptiles and Birds" and led to the establishment of an

American School of Neurological Research by his students, of whom Strong and Herick deserve special mention. As he himself stated, the new biological principles which he enunciated as a result of an inductive line of investigation, have not been universally accepted, but the environmental principles of adaptive radiation, polyphyletic evolution and homogenic classification have gained wide support amongst Palæontologists and, to some extent, among Zoologists.

President Osborn was a member of a large number of scientific academies and societies, and was also the recipient of a large number of medals and awards both in the United States and of the leading scientific societies all over the world. He was a foreign member of the Royal Society of London and was the only Zoologist to be elected as an Honorary Centenary Member of the Asiatic Society of Bengal in 1934. The writer had the privilege of meeting him first in 1925 on the occasion of the Meeting of the British Association for the Advancement of Science in Oxford and later in New York in 1930, and can never forget the impression created by his masterful personality. President Osborn was a charming man, pleasant and unassuming to talk to, and his interest in anything relating to Science and Education was all-absorbing. May his soul rest in peace!

B. P.

[*Note.*—The writer of this notice acknowledges his indebtedness to Osborn's *Fifty-two Years of Research* (1930) for details in reference to his life.]

The Snakes of India: A Historical Review.*

By Beni Charan Mahendra.

(*Department of Zoology, St. John's College, Agra.*)

INTRODUCTION.

THE recent publication of Gharpurey's book[1] on the Snakes of India affords a suitable occasion to present a historical review of the main works[2] on Indian Ophiology published so far. Such a review, it is hoped, would not only help interested readers to select what they want in this line, but would also probably suggest to prospective authors the scope for new ventures. Smith's volume on the Indian Ophidia[3] is now in course of preparation, and the present review has thus the further advantage of preceding a work, which is expected to give a fresh stimulus to the study of this fascinating group of animals.

The history of Indian Ophiology falls naturally into four main periods: First, the *Pre-Scientific Period*, which extended from times immemorial to somewhere towards the end of the 18th century and comprised numerous scattered observations on Snakes (partly correct, but mostly erroneous) in the Hindu religious books and traditions; secondly, the *Initial Scientific Period*, which dawned with the interest in Ophiology of some early English officials in India and is mainly represented to us in the works of Patrick Russell; thirdly, the *Pre-Modern Period*, which was ushered in by Günther (1864) and extended up to the publication of Boulenger's *Reptilia and Batrachia* (1890); and lastly, the *Modern Period*, which extends from 1890 to date.

All these four periods overlap to some extent, and the division cannot, therefore, be regarded as a rigid one. For the purpose of the present review, however, we find it most convenient and we hope that further work would only bear it out.

PRE-SCIENTIFIC PERIOD.

As far as we are aware, there is no ancient Indian book dealing exclusively with Ophiology, but scattered here and there one often comes across a great many notions and allusions about Ophidians in the Hindu scriptures. One of the Vedas[4] has several verses about them, and both *Mahábhárata* and *Bhavishya-purána* have much in them that is interesting in this connection. Perhaps here one might draw attention to Shripád-Dámodar Sátavalekar's "वैदिक सर्प विद्या" and to Jayadeva Sharma's articles in *Vijnána*,[5] as also to Fayrer's address[6] to the Victoria Institute, to Fergusson's *Tree and Serpent-Worship*, and to Tylor's *Primitive Culture*.

---

* The reviewer lays no claim to omniscience of the books published on Indian Ophiology. For the last nine years he has been interested in the subject and is acquainted with the more important literature. While he feels that he has not missed any important book on the subject he would be glad to know from readers whether any important publication has been omitted from the review.

[1] Gharpurey, K. G., *The Snakes of India.* Popular Book Depot, Grant Road, Bombay, 1935.

[2] With the exception of three series by Major Wall, which were published in the *Journal of the Bombay Natural History Society*, and which are, to all intents and purposes, books in their scope though not in their get-up and form, the present review is confined only to a survey of books and does not take notice of the numerous articles—taxonomic and otherwise—which appeared from time to time on Indian Ophiology in various scientific journals.

[6] Fayrer, Joseph, *On Serpent-worship and on the Venomous Snakes of India.*

INITIAL SCIENTIFIC PERIOD.

This period is principally represented to us by two volumes, which are probably the first scientific approach to Indian Ophiology in the form of a book publication. The first volume of Russell's *Account of Indian Serpents, collected on the Coast of Coromandel*[7] was published in 1796, and the second in 1801–1809. Both these volumes contained brief descriptions and "carefully executed plates" of various Indian snakes, but it must be pointed out that Russell "applied only the vernacular names to his specimens,"[8] which is rather unfortunate as vernacular names are in most cases variable and have only a local application, especially in a country like India where the language of the people differs so much from place to place. As Malcolm A. Smith[9] points out, "native names are often unreliable, except for the commonest forms. The same species may have a different name in a different part of the country, even though the language has not changed, or the same name may be applied to two different species. After all, it is not to be wondered at, for the country people have no great interest in reptiles except for the few that enter into their dietary."[10]

Patrick Russell, however, "was the pioneer of Indian Ophiology. He was the first person in India to distinguish the harmless from the venomous snakes, which he did by a careful examination of their teeth; he made also many experiments with animals to discover the toxicity of their poison....... A number of his preserved snakes and his collection of dried skins, some of which are the specimens from which his drawings were executed, are now in the British Museum (Natural History). The dried skins are carefully mounted on strong paper, and many of them still show the living colours remarkably well. He died in London. A good account of his life, with a portrait will be found in the second volume of his *Indian Serpents*, which he did not live to complete."[11]

PRE-MODERN PERIOD.

In 1864, a general work by Dr. A. Günther appeared on *The Reptiles of British India*,[12] and it contained descriptions of 180 species of Indian Snakes, along with those of other Reptiles. The work was "founded on the earlier publications of Russell, Cantor, Gray, Blyth, Jerdon, Kelaart, and others, largely supplemented by the author's own researches;"[13] but its main contribution to Indian Ophiology lay in proposing a new classification which was readily accepted by many subsequent workers (sometimes, with alterations) and lasted till the publication of Boulenger's volume in 1890.

As pointed out by Malcolm A. Smith, "the term India at that time was used in a much wider sense than it is to-day,"[14] and the area included by Günther practically comprised all the South-eastern Continental Asia. Amongst the earlier workers on Indian Herpetology, Günther occupies a premier position, and it is with some regret that one notes the omission of an account of his life from the short, excellent biographical sketches of the "best-known Indian and Indo-Chinese herpetologists" that Malcolm Smith gives us in the Introduction[15] to the First Volume of his *Reptilia and Batrachia*.

Eight years after the publication of Günther's Monograph, Fayrer (1872) made an extremely valuable contribution to Indian Ophiology in the form of a large-sized volume entitled *The Thanatophidia of India*[16] and published by J. and A. Churchill, London. The volume opened with four quotations from Shakespeare, was dedicated to the Right Hon. the Earl of Mayo, Viceroy and Governor-General of India, and contained 31 large plates, all but three of which were beautifully coloured and represented artistically the natural appearance of Indian venomous snakes. The last three (uncoloured) plates showed the method of handling a snake, the muscular apparatus for erecting fangs, the poison glands, the head shields of a colubrin snake, diagrams of fangs, skull, etc.

Fayrer's aim was to make "reliable information on the Venomous Snakes of India" generally available and he modestly claimed that in his book "there is no pretension to novelty in the description of the snakes." He chiefly based his classifications and definitions on Günther, or on other authors of repute, and the anatomical descriptions on those of Owen and Huxley, but he had "carefully verified their descriptions by comparison with, and by careful dissections of the snakes themselves". Most of what he writes is authoritative, and probably that is due to a "close observation of the principal Indian forms of poisonous snakes during life, for a period of more than three years". His main interest lay in the physiological action of snake venoms, and he performed 29 excellent series of scientific experiments *on the influence of snake poison on the lower animals, and on the value of certain modes of treatment and reputed antidotes*,[17] which have not so far been surpassed.

To say that Fayrer was an influential man is putting the matter too mildly. He was Honorary Physician to the Queen, Surgeon-Major, H. M. Bengal Army, Professor of Surgery and Senior Surgeon in the Calcutta Medical College and its Hospital, Fellow of the University of Calcutta, a President of the Asiatic Society of Bengal, F.R.S., F.R.S.E., and C.S.I. His position gave him many facilities in the way of Ophiological research that are denied to lesser men,

7 Russell, P., *An Account of Indian Serpents, collected on the Coast of Coromandel*. 2 Vols. London, 1796-1801 (known to the reviewer through Malcolm A. Smith's description).

8 Smith, Malcolm A., *Fauna of British India, Reptilia and Amphibia*, 1931, **1**, 3.

9 *Op. cit.*, pp. 1–2.

10 The reasoning is not very plausible. The country people of India are interested, for instance, in the Cobra, the Uromastix, the sacred Turtle of Jamuna, but none of these animals forms part of their dietary.

11 Smith, Malcolm A., *op. cit.*, p. 3.

15 Smith, Malcolm A., *op. cit.*, pp. 3-13.

16 Fayrer, J., *The Thanatophidia of India, being a description of the Venomous Snakes of the Indian Peninsula, with an Account of the Influence of their Poison on Life and a series of experiments*, J. & A. Churchill, London, 1872.

17 Fayrer, J., *op. cit.*, Section V, pp. 63-145.

and he was not a person to forego opportunities. By having an official circular sent round by the Inspector-General to Deputy-Inspectors-General of Hospitals, he collected an imposing array of cases of snake-bites with valuable data.[18] He addressed letters to the Secretaries or Political Agents of Bengal, North-West Provinces, Punjab, Oudh, Central Provinces, Central India, Rajputana, and British Burmah, and collected statistics about deaths from snake-bites, which are really imposing.[19] After a careful study of all the methods of treatment of snake-bite available in his days, he gave in his book an excellent account of the subject, together with "suggestions for the immediate treatment of persons bitten by venomous snakes".[20] *The Thanatophidia* ends with 8 appendices, the third of which contains an account of the use of snake-venom in Áyurveda (*i.e.*, "by the Kabirajes of Bengal"), and the fourth with the four classes of snake-charmers found in Bengal.

Besides this monumental work, Fayrer was a frequent contributor to the *Proceedings of the Royal Society* on matters pertaining to Indian Ophiology, and it is interesting to note that he, in collaboration with Brunton, was the first to discover the antidotal power of permanganate of potash and chloride of gold in cases of snake-bites.[21] Some of his papers, originally published in 1873–1904, were collected together by Brunton and reprinted in the form of a book[22] in 1909.

Fayrer's *Thanatophidia*, though a first-rate contribution to Indian Ophiology, is unfortunately large, unwieldy and expensive, and thus it was felt necessary to issue a shorter work which might be treated as a hand-book by "the busy officials of India" for the recognition of any of the poisonous snakes of this region. This was the occasion for a smaller volume by Ewart,[23] which contained 21 coloured plates of snakes borrowed from Fayrer, a short introductory chapter on "Symptoms and Treatment of Snake-Poisoning," concise accounts of the more important venomous snakes and a glossary at the end to help the layman to a meaning of the words used.

In 1874, Nicholson published a small book on *Indian Snakes*,[24] which—though not so imposing as Fayrer's work—is full of valuable information and original observations. Nicholson was a keen student of Indian Ophiology and loved to study the snakes and their ways as much in their natural surroundings as in a museum. He started to give the readers a hand-book of Indian Snakes, and he succeeded in producing a volume which is certainly true to the sub-title *An Elementary Treatise on Ophiology*. Beginning with a short introduction assigning the proper place to Ophidia in the scheme of scientific classification, he proceeds to deal in the First Part of his book, with the anatomy of this group of animals. The skeleton, the mouth and teeth of harmless and venomous snakes, the internal organs, the senses and the integument are all treated concisely though clearly, much of the material probably having been derived from Owen and Schlegel. In the Second Part of his book, he classifies the Indian Ophidia, gives a Phylogenetic Tree based on his own studies, and describes the Indian forms carefully. The Third Part deals with the natural history of snakes and does much credit to Nicholson's interest in Indian Ophiology. His chapters on "The Snake at Liberty," "The Serpentarium," "Schemes of Extermination," and "Snake Mythology" are full of original matter, and some of them, at any rate, must have necessitated much thought and patient observation. It appears that not satisfied merely with the study of preserved specimens, Nicholson used to keep live snakes with him and to observe them carefully, besides going out snake-hunting off and on. In the chapter on "Museum" he gives valuable information for the preservation of specimens and other allied matters, and in that on "Snake-Poison and Antidotes" he adds some information of his own to a survey of what was already known on this subject.

One feels tempted to make an interesting quotation from Nicholson, partly because it forms really good advice and partly also because it gives us a clue to the mentality of this author. He says,[25] "From the eagerness of people to look for the marvellous in all that concerns snakes, the observations of non-scientific enquirers are always open to suspicion. On this subject, the safest plan is to believe nothing that you hear, and only half what you see yourself, guarding carefully against the liability of your visual impressions being influenced by your expectations and pre-conceived ideas."

Two years after the publication of Nicholson's work and twelve years after that of Günther's, another general work[26] on the Reptiles of British India appeared with the object of meeting "a want which......blocks the way to the general study of Herpetology in India, and to supply in an accessible and portable form such a condensed description of our Indian Reptiles as may enable any one interested in the Fauna of his locality to acquaint himself with the Reptiles he meets with." Theobald's *Descriptive Catalogue of the Reptiles of British India* was based on Günther's work, but it excluded 'Hydrophidæ' and the 'Batrachia' from its scope, and restricted itself to British India alone. To a great extent, it was "virtually an abridgment of Günther's, but with the numerous discoveries and observations of Stoliczka, Beddome, Anderson, and of the author himself added to those of Günther,

many additions by the latter having been made after the publication of his large work on Indian Reptiles."[27] It contained descriptions of 225 species of Ophidians, while Günther's Monograph —in spite of the larger geographical region that it dealt with—had described only 180 species.

Theobald's book is deficient in illustrations, there being only two on page iii of the Appendix, and his descriptions do not aim to be exhaustive, but include, as he says, "only so much detail ......as will enable the student to specifically determine" any species. Following 4 pages of "Errata et Addenda," the text concerns itself with systematic descriptions of the orders, families, genera and species of various reptiles, 126 pages being devoted to the order Ophidia. A list of non-Indian species included in Günther's Monograph is given, as also an Index of the Genera and species of Indian Reptiles and a Key for their identification. The book ends with an Appendix dealing with "the means of discriminating between poisonous and harmless snakes and the treatment of snake-bite."

Much work has been done on Indian Ophiology after Theobald, and thanks to the labours of Major Wall, we have now a better key for the distinction of venomous[28] from non-venomous snakes. Still, however, the following advice by Theobald bears reiteration: "Perhaps, the simplest way of learning what are poisonous snakes, would be to pass an hour or so in some museum where acquaintance might be made with the commoner or more deadly species."[29] After all, both Boulenger's[30] method of the examination of dentition and Colonel Wall's of scrutinising the scales are applicable only to dead specimens and fail when the snake is fully alive and vigorous. Then it is *only* Theobald's advice which might be of some use. We have to know the poisonous snakes individually in order to be able to pronounce judgment on live ones.

MODERN PERIOD.

The modern period in Indian Ophiological research begins with the publication of Boulenger's volume on *Reptilia and Batrachia*[31] in 1890. Boulenger was already famous for the laborious Catalogues[32] of the Reptiles in the British Museum that he had prepared, and he had made his mark as a first-rate herpetologist. His volume on Indian Reptiles and Amphibians was readily accepted as a standard work, and although a number of the species described by him have undergone changes in the light of further work, his book still forms the basis of taxonomy about these animals. He gave us a new classification for the Ophidia, a classification which is regarded by most Ophiologists as "a logically-conceived system, by far the best hitherto proposed,"[33] and which has been implicitly followed by later workers. The previous classification of the Ophidia was due to Günther, and consisted essentially in the division of this Order into 21 families, arranged into four suborders: *Hopoterodontes, Colubriformes, Colubriformes venenosi, Viperiformes.* Boulenger, however, recognised only 9 families and assigned the rank of sub-families to several previously called families. The section on Ophidia in his book contains descriptions of 264 species and occupies 200 pages.

Starting with an extremely short introduction about the Ophidia (pp. 232–33), mainly concerned with the characteristic peculiarities of the order and with remarks upon the distinction between poisonous and non-poisonous snakes, the poison-glands and fangs, he gives a Synopsis of the Families, followed by systematic descriptions. The section on Ophidia is illustrated with 59 carefully-drawn figures. As pointed out in the Preface, "the classification of the Snakes, which comprises nearly one half of the Reptilian species known to occur in India, is new, and all the descriptions of families, genera, and species have been prepared expressly for the present work. As there is no recent publication with a complete synonymy of the Ophidia, somewhat fuller references to the literature of the subject have been rendered necessary than in the other suborders of Reptiles and Batrachians."[34]

Boulenger's volume, apparently designed for the scientist, is written in such a compact and concise manner as not to be of much use for the layman. His descriptions of species and genera are models of compression, and he does not explain the terms that he uses. The lengths mentioned in the description of the species are apparently the maximum that he found, and he notes the habitat of each species that he records.

In 1891, Sclater published a *List of Snakes in the Indian Museum*,[35] a book containing x + 79 pages and giving no descriptions of any species at all, but only details about the place and date of collection, the name of the collector, etc., of the Ophidian specimens then in the Indian Museum. Under the name of each species is given the name of "the Author of the specific name and a reference to the best description, not necessarily the original one, to which" the author had "been able to get access". Sclater adds 14 more species to those described by Boulenger, and gives a list of those species of snakes which were not in the Indian Museum.

From 1895 to 1925, we find an indefatigable

worker in the person of Colonel Frank Wall in the cause of Indian Ophiology. "He collected in all parts of the Indian Empire, and by his energy and enthusiasm stimulated others to make collections for him. For many years he has been the chief authority on Indian snakes. He visited in turn every museum in India and overhauled their collections. He was a prolific writer, and managed to combine admirably the scientific and popular sides of the subject. He was a constant contributor to the *Journal of the Bombay Natural History Society*, but wrote also for other Indian journals. The types of the numerous snakes described by him, together with many other specimens, are in the British Museum (Natural History); the rest of his collections are in the museums in India, principally in Bombay."[36]

It is beyond the scope of the present review to make a survey of even the more important contributions of Colonel Wall to Indian Ophiology, but we have selected three series of his, published in the *Journal of Bombay Natural History Soci ty*, for inclusion here.

A Popular Treatise on the Common Indian Snakes[37] was published from 1905–1914, and ran into as many as 23 parts. It was copiously illustrated both with coloured plates and diagrammatic figures throughout, and must have necessitated patient research and close observation on Indian snakes for many years. Unfortunately the Bombay Natural History Society has not so far published it as a separate book, in spite of the fact that there is a general demand for such work.

The series begins with the intention of acquainting the readers with the common snakes of India and it fulfils its purpose remarkably. As the author himself says, "there is no book on the subject written in popular language, and the few that show coloured plates are very expensive, while accuracy of detail seems to have been largely sacrificed for pictorial effect.... The descriptive parts of the best works are couched in terse and scientific language, and though excellently written by experts in museums the authors have had no facilities for observing the habits of creatures they only see in spirit on museum shelves. We must, therefore, rely upon those who actually come into contact with living snakes to supply such information."[38] Wall's series supplies such information to a very great extent.

The whole series is excellently written to evoke popular interest and within its scope, has not been surpassed up to the present time. Wall takes one species after another, and like an adept scientific snake-charmer, gives particulars about nomenclature (scientific, English and Vernacular), dimensions, bodily configuration, colour, identification, haunts, disposition, food, breeding habits, and what not. One often wonders at the amount of knowledge he has garnered, and admires his clear mode of expression.

In 1906, appeared a much shorter series by Wall: *The Poisonous Snakes of India and How to recognise them*;[39] and this series was later published in the form of a book[40] in 1908, with many alterations and changes. The book is an authoritative contribution to the subject and so far as we know, has already passed through 4 editions. Wall prepared a key [41] for the identification of poisonous from non-poisonous snakes in 1902, and the fact that the key met with much favour and was even circulated by the Inspector-General of Civil Hospitals in the Central Provinces, seems to have encouraged him to write this series.

A third series[42] by Colonel Wall, entitled *A Hand-list of the Snakes of the Indian Empire*, was written for the field naturalist, and set out to enumerate all the species of Indian ophidians known at that time, besides giving such details as type, length, lepidosis, distribution, etc., in a concise manner. It serves as a good supplement to Boulenger's work, and makes the taxonomic work of later years accessible to the reader.

In 1914 was published a much less pretentious book by Cazaly,[43] only 60 octavo pages in extent and designed to help the layman to an identification of the commoner snakes of India. The book is written in extremely simple language, does not claim to add anything new in the form of facts, and relies for its information on Nicholson's *Indian Snakes* and Wall's *Poisonous Snakes*, and for names on Boulenger's *Catalogue of Snakes*.

In 1919, Roberts[44] made a curious collection of the details of the *remedies that are employed by the native physicians of Ceylon and India in the bites of snakes and other animals, and in the stings of animals*. Although we cannot support the use of these medicines as there is no scientific backing for them, we have been much interested in the book itself, and especially in the specimens of "magical spells"[45] given in it.

D'Abreu's *The Snakes of Nagpur* (1916),[46] Wall's *The Snakes of Ceylon* (1921),[47] and Prater's *The Snakes of Bombay Island and Salsette* (1926),[48] are all restricted in the geographical area that they deal with, but are good in their own spheres.

48 Prater, S. H., "*The Snakes of Bombay Island and Salsette*" [*Bomb. Nat. Hist. Soc.*, 1926].

In 1923, Wall gave us an invaluable book on the *Identification of Indian Snakes*,[49] full of keys and synopses that have proved almost infallibly useful to the reviewer for the last 9 years and represents a laborious research on the part of the author for very many years. Wall says, "In my early days in India when I began to take up the study of snakes I found it extremely difficult to find out the names of the commonest specimens I encountered. The books on the subject then available gave little, if any, help to one like myself a beginner. The keys given to assist the student were very unsatisfactory, being too scientific. Often indeed one had to investigate difficult points which called for skilled dissection, points concerning peculiarities in the dentition, or even the more difficult matter relating to processes such as those of vertebræ. Very few men in India have the inclination or skill necessary to investigate such points, still fewer have leisure hours sufficient to undertake such a laborious and difficult task. In consequence many with a natural bent for biological research are deterred from taking up a subject which would provide endless interest, and pleasure, especially to men who are often alone in camp, on tea and coffee plantations, or who have joined the Indian Forest and other services."[50] For such people and others, even for workers in museums, Wall offers the fruits of his labours in this book, and we are sure that an identification arrived at by his methods, if confirmed later by a reference to Boulenger's work or some other standard volume, would be unimpeachable.

Wall's keys and synopses are based on a study (mostly statistical) of the scale characters of Indian ophidians, and as he himself points out, they have been assailed on the ground that they "are not natural ones, but what some reviewers of" his "past work term 'unscientific'. The only drawback we find in them is, that they give no idea about Ophidian *genera*, and especially in the case of such a family as *Colubridæ*, not only bring together forms that are believed to be much apart from each other, but also separate allied species from one another. In some cases the same species (*e.g.*, *Coluber helena*, *Zamenis arenarius*, *Naia tripudians*, etc.) occupies two or more different positions in the same synopsis.[51] Besides, in a chart like that for the genus *Silybura*[52] or *Rhinophis*,[53] too much stress has apparently been laid on the relative proportions of the head shields and little allowance made for the play of individual variations that one is apt to find so often in nature.

In 1929, a rather large book appeared "from the pen of a layman," Paresh Banerji,[54] which was not really a contribution to Indian Ophiology, but a sort of advertising campaign by the writer in favour of a specific ("Lexin") that he claimed to have invented for snake poisoning. The book was, on the whole, well published and had several coloured plates of Indian snakes; but unfortunately, a greater part of it was devoted to substantiating the 'efficacy' of the 'supposed' snake specific, and it contained as many as 1134 reports of cases in which Lexin was said to have cured snake-bites.

This brings us to the latest book published on the subject: that by Gharpurey (1935), which is a popular contribution to Indian Ophiology, and is written with the object of enabling laymen to distinguish poisonous from harmless snakes and of giving information about the common forms met with in India. The author claims an interest "in the subject for over 25 years, being drawn to it mainly by the heavy mortality figures," and he has drawn largely for his materials on such standard books as those by Wall, Fayrer, Nicholson, etc. He modestly says, 'that there is hardly anything original in this book," but still he has made careful compilation of a huge amount of information about Indian snakes and he has presented his subject in a simple and lucid manner.

CONCLUSION.

In spite of much good work done on Indian Ophiology in the past, there is still a great deal of scope for further investigations in this subject, and it is hoped that more and more workers would take an active interest in it and add their contributions. True it is, that "systematic collecting has been carried out in nearly all parts of the Indian Empire, and, except in the more inaccessible mountain districts, the herpetological fauna of the country is now pretty well known."[55] But "in the exact distribution of the species, in their individual variation, in habits, life-histories, in fact in bionomics generally, a vast amount of investigation has still to be done," although "for the mere collector in search of new species no great field remains."[56]

Research Notes.

Theory of Meromorphic Functions.

LARS AHLFORS ("über erine Methode in der Theorie der Meromorphen funktionen," *Com. Phy.-Math.*, T. **8**, Nr. 10) has contributed a valuable paper on the introduction to the theory of meromorphic functions. After the fundamental contribution of Rolf Nevanlinna characterised by his first two fundamental theorems, the introduction was simplified in two directions. One was due to the Japanese workers headed by Shimuzu and the other was due to the Finnish school headed by Selberg and Frithiof Nevanlinna. Combining and crystallising all these methods the author has proved the chief properties of the characteristic function $T(r)$, and has deduced the second fundamental theorem of Nevanlinna in 14 pages. The ideas underlying the contribution are these:—First of all $m(r, a)$ is defined to be

$$\frac{1}{2\pi}\int_0^{2\pi}\log\frac{1}{\{f,\ a\}}\,d\theta$$

where $f(z)$ is the meromorphic function and (a, b) denotes the straight-line distance between the stereographic projections of a and b on a sphere of diameter unity touching the plane at the origin. (This is essentially the same as the earlier definition of Nevanlinna.) $N(r, a)$ is defined to be the same. Next by a simple differentiation and applying the principle of argument the independence of $T(r, a)$ w.r.t. a is deduced. There is no need to apply the Poisson-Jensen formula at all. Next taking $\rho(a)$ to be any positive function such that $\oint \rho(a)\,d\omega(a)$ taken over the surface of the sphere $= 1$, he has shown in a single step that if

$$m_\rho(r) = \oint m(r,\ a)\ \rho(a)d\omega(a) \text{ and } N_\rho(r) = \oint N(r, a)\ \rho(a)d\omega(a).$$

then $T(r) = m_\rho(r) + N_\rho(r)$ also. From this he has easily deduced the convexity of $T(r)$ w.r.t. $\log r$. This is extremely simple when we remember the fact that this is proved by Nevanlinna by making use of the properties of the Green's function corresponding to a ring-region. The second fundamental theorem of Nevanlinna is obtained as a corollary of this result by taking a suitable density function $\rho(a)$; *viz.*,

$$\operatorname{Log}\ \rho(f) = c + 2\sum_1^q \operatorname{Log}\frac{1}{\{f,\ a_\nu\}} - \alpha\log\left[\sum_1^q\log\frac{1}{\{f,\ a_\nu\}}\right]$$

where c is a normalising constant and α is any number > 1. Some words are to be said with respect to the form of the theorem we obtain when we consider functions meromorphic in the unit circle. We get

$$\sum_1^q m(r,\ a_\nu) < 2T(r) - N_1(r) + \log T(r) + k'\log\frac{1}{1-r} + 0\ (1)$$

except in a set of intervals I_t such that $\Sigma\int_{I_t}\frac{dr}{(1-r)^{1+\epsilon}}$ is finite, k' being a constant which can be made as near to unity as we like. This is much sharper than the corresponding theorem by Nevanlinna and others and in fact as sharp as the result obtained by F. Nevanlinna by the use of suitable modular functions.

The second fundamental theorem mentioned here is not the *proper*—Nevanlinna by applying his *proper* second fundamental theorem in connection with his proof of Picard-Borel theorem. The proper theorem itself is applied by Nevanlinna to deduce further theorems, such as the theorems of unicity, etc. Probably these theorems can all be deduced directly by Ahlfors's method, but the proper theorem itself can be proved by Ahlfors's method as follows. Take

$$\rho(f) = k\frac{1}{\{f,\ \infty\}^2\{f,\ 0\}^2}\left[-\log\frac{\{f,\ \infty\}}{\{f,\ 0\}}\right]^{-\alpha}$$

where $\alpha > 1$ and k is the normalisation constant. After some further analysis it can be proved that

$$m_r\left[\frac{f'}{f},\infty\right] \leqslant \tfrac{1}{2}\log\left[\lambda(r)\right] + \alpha\log T(r) + 0\ (1)$$

where $\log\lambda(r) = 0[\log r + \log\ T(r)]$ except in the exceptional intervals. It should also be mentioned that this is the sharpest form in which the theorem is put. In fact if we work out the values of the actual constants we get a much sharper form than that obtained recently by Shimuzu and others.

K. V. I.

Uniform Distribution of Points.

KOKSMA ("Ein mengen theoretischen Satz uber die Gleich-verteilung modulo Eins.," *Comp. Math.*, **2**, Fasc. 2, pp. 250–258) has

recently contributed an interesting theorem concerning the uniform distribution of points $\{\theta^n\} = \theta^n - [\theta^n]$ (*i.e.*, the fractional part of θ^n.) He has proved that the distribution of such points is uniform in (0, 1) for almost all $\theta > 1$ (*i.e.*, excluding a set of points of measure zero utmost.) The most important theorem he proves in this connection is the following:—Let α and β be real numbers $\alpha > \beta$. Let $f(x, \theta)$ be a real continuous function of θ in $\alpha \leqslant \theta \leqslant \beta$ for every +ve integral value of x. For every $x_1 \neq x_2$, let $\phi(x_1, x_2, \theta) = f(x_1, \theta) - f(x_2, \theta)$ be a continuously differentiable function of θ (*i.e.*, its differential derivate ϕ_θ' is monotomic and $\neq 0$. Let

$$A_N = \frac{1}{N^2} \sum_{x_1=2}^{N} \sum_{x_2=1}^{x_1=1} \text{Max} \left[\frac{1}{|\phi'_\theta(x_1, x_2, \alpha)|} \frac{1}{|\phi'_\theta(x_1, x_2, \beta)|} \right]$$

and N_ν be a sequence such that ΣA_{N_ν} converges and $\frac{N_{\nu+1}}{N_\nu} \to 1$. Then $\{f(n, \theta)\}$ is uniformly distributed for almost all θ. The proof of this theorem is established by utilising Weyl's criterion, *viz.*,

$$\frac{1}{N} \sum_{1}^{N} e^{2\pi i f(n, \theta)} \to 0 \text{ with } N \to \infty.$$

From this the result follows as a particular case.

K. V. I.

Creation of the Radio-Elements belonging to a New Radioactive Family.

So far there were only three radioactive families known namely (1) the thorium series with atomic weights of the form $4n$ where n is an integer, (2) the radium series with mass numbers expressed by $W = 4n + 2$ and (3) the actinium series with $W = 4n + 3$. A series of the form $W = 4n + 1$ must consist of unstable elements since they do not occur normally in nature. Now I. Curie, H. von Alban Jr. and P. Preiswerk (*Journ. de Physique*, 1935, **6**, 361) have artificially produced some elements which they have definitely proved to belong to this family. Since Fermi has shown that slow neutrons have a large probability of being captured by a nucleus resulting in the formation of an isotope having the mass number greater by one, they bombarded Thorium with slow neutrons. The new element formed was expected to be β-active and hence to prove its existence, the Thorium had to be carefully purified to remove the radiothorium associated with it. After addition of Ba and Pb and Bi and precipitation with H_2SO_4 and H_2S respectively, La was added and the Thorium precipitated with H_2O_2. The hydroxide formed was converted into nitrate or chloride and dried before irradiation. The Thorium was placed in a bakelite case with a cellophane covering since such a case was found to be free from activity when irradiated. The β-activity was examined by means of a Geiger-Müller counter of thin aluminium 0·2 mm. thick. The activity curves were analysed and showed products of 1 min., 25 min. and 3·5 hrs. periods. These were chemically separated and then the repetition of the analysis showed two new products of periods 2·5 min. (associated with the 25 min. product) and 12 min. When the irradiated thorium was precipitated with H_2O_2, the 25 min. product came down with it showing that it is an isotope of Thorium. Addition of paraffin with consequent slowing down of the neutrons increased the yield of this product thus confirming the above view.

The 3·5 hrs. product accompanied La in the chemical separation thus showing itself to be an isotope of actinium. The 2·5 min. product was shown to arise from a Thorium isotope and to be an isotope of protactinium and hence the conclusion was drawn that the 2·5 min. product was produced from the 25 min. product. The several results could be explained on the basis of the following equations:

$${}^{232}_{90}\text{Th} + {}^{1}_{0}n = {}^{233}_{90}\text{R (25 min.)}$$

$${}^{233}_{90}\text{R (25 min.)} \xrightarrow{\beta} {}^{233}_{91}\text{R (2·5 min.)}$$

The production of the 1 min. product which was shown to be an isotope of radium was explained as follows:

$${}^{232}_{90}\text{Th} + {}^{1}_{0}n = {}^{229}_{88}\text{R (1 min.)} + {}^{4}_{2}\text{He}$$

$${}^{229}_{88}\text{R (1 min.)} \xrightarrow{\beta} {}^{229}_{89}\text{R (3·5 hrs) (isotope of actinium)}$$

The 12 min. product probably results from the process:

$${}^{232}_{90}\text{Th} + {}^{1}_{0}n \to {}^{232}_{89}\text{R} + {}^{1}_{1}\text{H}.$$

Thus the new radioactive family is probably developed thus:

$${}^{237}_{92}\text{R} \xrightarrow{\alpha} {}^{233}_{90}\text{R (25 min.)} \xrightarrow{\beta} {}^{233}_{91}\text{R (2·5 min.)} \xrightarrow{\beta} {}^{233}_{92}\text{R} \xrightarrow{\alpha} \text{etc.}$$

A search for the origin of this family ${}^{237}_{92}\text{R}$ in Uranium minerals was however without result.

T. S. S.

Electrets.

M. EGUCHI performed a remarkable experiment in 1925. A suitable wax was poured in the molten state into a condenser, a voltage was applied, and the wax allowed to solidify under the electric stress. The result was a permanently electrified body, an "electret," which retained its charge constant over a period of more than a year. In a recent paper (*Phil. Mag.*, 1935, **20**, 929) A. Gemant has carefully studied these highly interesting electrical analogues of permanent magnets, and finds that there are two possible kinds of charges, one having the opposite sign to the adjacent polarising electrode, of short duration, and caused by ionic space charges. The other has the same sign as the adjacent polarising electrode. It is caused by orientation of dipole molecules leading to an oriented crystallisation and accompanied under circumstances by a secondary piezo electric effect. This charge is the steady one, and is of great interest. Technical applications for such electrets can be found in the construction of electrometers and in a kind of electrostatic microphone.

M. A. G. RAU.

The Hammersten Effects.

J. W. McBAIN (*J. Am. Chem. Soc.*, 1935, **57**, 1916) has cleared up much of the confusion that has arisen by calling different Phenomenon "Hammersten Effect". Linderstörm-Lang conferred the name to the fact that the osmotic coefficient of the thymonucleates depends upon the size of the kation. Pauli and Valko and later others, included under this term the fact that in certain colloidal electrolytes the osmotic coefficient (obtained from freezing point lowering) is far less than that necessary to account for the hydrogen ion alone as measured by the electromotive force. McBain classes the former as the genuine Hammersten Effect and has put forth a new explanation of the same based on steric hindrance to close packing. The second phenomenon (the "Hammersten Effect" of Pauli) appears to be more fundamental in view of the considerations of McBain. The divergence between the freezing point and the electromotive force data finds a rational explanation on the basis that the activity coefficient of the hydrogen ion is about half of that of the chloride ion in the concentrated solutions of hydrochloric acid. This marks one of the very first steps in getting at the individual activity coefficients of the ions without making any arbitrary assumptions.

K. S. G. D.

The Use of Ortho-para Hydrogen Conversion in the Detection of Free Radicals.

THE fact that paramagnetic substances can catalyse the ortho-para conversion of hydrogen has been used for the first time in the detection of free radicals by W. West (*J. Am. Chem. Soc.*, 1935, **57**, 1931). He finds definite indications of the production of paramagnetic free radicals on illumination of methyl iodide and acetone. On the other hand, propionyl iodide does not seem to give rise to free radicals under similar conditions. This is pointed out as a strong evidence in support of Norrish's hypothesis of a difference in mechanism in the photo-dissociation of aliphatic aldehydes and ketones.

K. S. G. D.

Deuterium as an Indicator in the Study of Intermediary Metabolism.

IN a series of four papers published in the *Journal of Biological Chemistry* (1935, **111**, 163–192), Rudolf Schœnheiner and D. Rittenberg have published the results of their work on intermediary metabolism, employing a very elegant and novel technique. The difficulty of following the course of transportation of normal physiological substances in the body and their conversion into other substances has long been realised and very often laborious experiments have yielded uncertain results. While the use of synthetic derivatives for following the metabolism of physiological substances has yielded interesting results, the method is open to the objection that such derivatives are not natural, and it is open to doubt whether they successfully imitate the physiological substances whose metabolism is under investigation. By replacing one or more of the elements in the molecule of the substance, by their respective isotopes, it is reasonable to expect that the chemical properties of the substance will not be greatly altered. Schœnheiner and Rittenberg have employed this method and by replacing the hydrogen in the organic compound by its heavy isotope, deuterium, which is capable of being detected with a precision of 0·001 per cent. they are enabled to follow the fate of such substances after administration to animals. The employment

of deuterium as an indicator opens out a new chapter in the study of metabolism.

For a successful working of the method, the deuterium should be placed in the molecule in such a position that it is not interchangeable with the hydrogen of water. It was, therefore, necessary to introduce deuterium into carbon groupings by catalytic hydrogenation of unsaturated compounds. The application of the method is, therefore, restricted to the substances containing *stable* hydrogen. "A substance like oxalic acid cannot be investigated as the two hydrogens in it are labile." The method gives information only on processes in which the hydrogen (deuterium) remains fixed at the carbon atom, but not on the fate of these carbon atoms to which deuterium is not attached. There may be a few other reactions which restrict the universal application of the method and further work will be necessary to understand such limitations.

As a result of the experiments on mice fed from 2 to 10 days on a diet comprising 20 per cent., 4 per cent. and 1 per cent. deuterium-containing fats, the authors conclude that the largest part of the dietary fat, even when present in small quantities, is deposited in the fat tissues before it is utilised

The application of the method to the investigation of the intermediary products in the general cholesterol metabolism has yielded very interesting results. Thus, cholestenone is an intermediary substance in the sterol metabolism. It is probable that it is formed from the oxidation of cholesterol as a first step, and is then reduced to coprostanone.

Further applications of the method will be awaited with interest.

B. N. S.

On the Biology of the Psyllidæ (*Homoptera*).

THE work of R. U. Mathur (*Indian Forest Records*, 1935, Entomology Series, Vol. I, No. 2) on the biology of the *Psyllidæ*, furnishes important details about the habits, life-history and economic value of a family of insects that has long remained comparatively untouched by Entomologists in India generally; not only in economic (Forest) but in taxonomic entomology as well, this work supplies a long-felt want, specially for investigators in forest Psyllid fauna all over India; indeed these valuable notes will also guide economic entomologists in India, in their study of Psyllids, as affecting cultivated crops of all kinds.

B. K. M.

Immature Stages of Indian Coleoptera (*Scarabœoidea*) and Eucnomidæ.

THE studies of immature stages of Insects in general and of Coleoptera and Lepidoptera specially, cover a very large field and offer great scope. In insect classification, the custom has mostly always been to take into consideration the taxonomically valuable characters of the imaginable stages, to the utter exclusion of the several important features of the larval or immature stages. This has not only rendered classification incomplete but has made the task of Coleopterists and Lepidopterists, in specific determinations based on characters of larval instars, doubly difficult, and well-nigh impossible.

The descriptions of the immature stages of Scarabæoidea, particularly, are of vital interest to economic entomologists who have frequently to deal with the larval stages of Scarabiid, Melolonthid and Rutellid beetles; considerable damage is caused to the roots of cultivated crops of all kinds by them and an exact knowledge of their important features largely facilitates not only correct determination but effective control. Entomologists all over India welcome the valuable work of J. C. M. Gardner, (*Indian Forest Records*, 1935, Entomology Series, Vol. I, Nos. 1 and 4) on the immature stages of Coleoptera.

B. K. M.

Asexual Reproduction in Tunicates.

N. J. BERRILL in his paper on the Asexual Reproduction in the Tunicata ["Studies in Tunicate Development," *Phil. Trans. Royal Society, London*, (B), 1935, **225**, No. 526] has described the nature of budding in twenty genera of ascidians; eight of them are described for the first time, such as, Diazona, Tylobranchion, Morchellium, Euherdmania, Eudistoma, Archidistoma, Pycnoclavella and Chonorostachys. He has noted that the majority of the forms possess a regular alternation of sexual and asexual phases which coincide more or less with summer and winter, but the onset of budding seems to be dependent more on the physiological conditions of the animals than on the change of environment. The budding results in a tendency on the part of the zooid

to degenerate, the degeneration being brought about by autolysis or regression in an antero-posterior direction, which is associated with the formation of yolk-laden trophocytes. The posterior extension of migration of the trophocytes depends upon the presence or absence of the posterior-abdomen, enlarged ventral vessel and other similar factors. The medium of nutrition for the bud may be fluid where there is a physical continuity or by trophocytes in cases of physical isolation. During autolysis the tissues least specialised survive readily and the presence of at least one unspecialised cell is necessary to the development of a new individual, and buds are isolated from the parent by transverse constrictions and where a part of the old alimentary tube is present, the development is only a case of regeneration, while, where it is absent it is only reorganisation of the contained tissues. The author has contradicted the accepted view that the vascular septum of the ventral vessel has no connection whatever in embryonic development with the pericardium of the adult and hence cannot be considered as extension of the epicardium into the ventral stolon. He points out that though it is assumed that the mode of budding is primitive, there have been two major trends in specialisation, the one culminating in Distaplia, Diplosoma and probably Thaliacea where the type of budding is localised being epicardial and œsophageal, and the other through the posterior extension of zooids and buds to form Synoicids, Clavelinids and possibly ending in Perophoridæ, and the budding in the Botryllidæ and Polystylidæ is only a reacquisition of the faculty and not phyletically continuous with any other type.

Spermatogenesis of Man.

J. B. GATENBY AND H. W. BEAMS have for the first time described the behaviour of the Cytoplasmic inclusions during Spermatogenesis in man (*Quart. Journ. Micros. Sci.*, 1935, **78**, Pt. 1, No. 309). While the general behaviour of the constituents probably does not differ from that found in many other mammals, there are certain important variations which are pointed out by the authors. Three types of golgi apparatus can be distinguished; that in the sertoli cells being filamentar while it is sub-spherical in the spermatocytes and semi-dispersed in the spermatogonia. During division, the golgi apparatus breaks up into a large number of very small bodies which show a tendency of grouping round the nucleus rather than round the asters. The mitochondria are granular throughout and probably do not differ from the mitochondria in other mammals. The rôle of the centriole appears interesting. The single centriole of the spermatid soon divides into two which move close to the cell-membrane. The flagellum arises from both of them and the distal one becoming larger, assumes a ring-shape. The whole apparatus moves close to the nucleus and the proximal centriole is eventually seen to attach to the nuclear membrane. The distal ring-shaped centriole moves a certain distance down the flagellum and marks the posterior end of the middle piece. The authors describe a neck granule in addition to the two centrioles, embedded in the posterior part of the nucleus close to the proximal centriole. They do not attach any relation between this body and the centrioles and tend to think it is a derivative of the nucleus. The golgi apparatus takes very little part in the formation of the acrosome, a single bead-like body developing within the archoplasmic area becoming attached to the nuclear membrane and giving rise to the acrosome. The rest of the golgi apparatus is discarded. A post-nuclear cap is described. The sperm head has a vacuole whose function is not determined with certainty. Crystals, of either rod, batonette or pointed shape are found in a number of cell-elements of the testis and are probably no more than reserve nutriment in the cells.

The Cranial Morphology of Some Examples of Pelobatidæ (Anura).

W. K. PARKER described the gross structure of the skull of various anuran examples as early as 1881 and recently, however, the subject has received greater attention and has been studied by modern methods. In a paper in *Anat. Anz.* (Bd. 81, Nr. 4/6, S. 65–96) Mr. L. S. Ramaswami has described some aspects of the cranial morphology of the two pelobatid examples Scaphiopus and Megophrys. The cranial anatomical features of these forms are compared with those of the ancestral group "Liopelmidæ". Further, it is pointed out that Megophynæ, which according to Noble occupies a basal position, anticipates some of the characters of the next group—the pelobatinæ, of which

Scaphiopus has been studied. Moreover, Scaphiopus possesses certain exclusively individual characters. Thus the Nobelian viewpoint, that in the order of evolution, Megophrynæ occupies the lowest while Sooglossinæ the highest rungs, is questioned. The author suggests that the three sub-families Megophrynæ, Pelobatinæ and Sooglossinæ are all of equal rank and they have moved on parallel lines.

The Atomic Nucleus.

[Prof. Born first explained how he had chosen to talk about the nucleus although his main line of work was not nuclear structure: the intimate touch with the pioneers in nuclear Physics, which he had during his stay at Cambridge, was influential in his choice. Incidentally he referred the audience to his new book *The Restless Universe* with its novel illustrations which produced the same impression as a cinematographic picture when the leaves of the book were rapidly turned over. The lecturer then proceeded to give a very lively discourse on the discovery and investigation of atomic nuclei.]

THE view that an atom consists of opposite electric charges concentrated at a great distance from each other and not uniformly distributed throughout the atom was put forward by Lenard in his theory of dynamides, long before Rutherford proposed the nuclear theory of the atom. The idea behind the attempts to unravel the mystery of the nucleus was to pierce it by swift particles and thus gain a knowledge of its contents just as a closed mechanism has to be taken to pieces in order to lay bare its inner details. The discovery of Radioactivity had placed such swift projectiles in the hands of the physicist. The radioactive elements like Uranium, Polonium and Radium emit three different kinds of radiation which were named α-, β- and γ-rays. The α-rays consist of helium atoms which have lost two electrons, the β-particles are swift electrons and the γ-rays are waves like X-rays but of higher frequency. It was natural that Rutherford who had done important work in Radioactivity should study the effect of bombarding different substances by means of α-particles. It was also natural that one of the best means of studying the tracks of these particles, *viz.*, the Wilson cloud chamber should have been invented in England which is famous for its fog. When a sudden expansion is caused to take place in a chamber saturated with water vapour, the fall of temperature produces supersaturation and the vapour will condense into drops wherever some dust or charged particles are present. Since the α-particles are heavy projectiles with high energy their path is thickly studded with charged ions and droplets forming on these show the track of the α-particle as a thick straight line. Just as the projectiles from a heavy gun spread swift destruction thickly along their path while the bullets from pistols produce here and there a chance casuality and are also more easily turned from their course, the β-particles in contrast to the α-rays, produce zig-zag tracks sparsely covered with droplets. The γ-rays, on the other hand, first produce electrons along their path and the tracks of the latter then show up the passage of the γ-rays.

The experiments of Rutherford on the scattering of α-particles showed that these particles were generally deflected by small amounts, but now and then there occurs a very large deviation. Rutherford saw that such a deviation was like the passage of a comet round the sun and applying a similar calculation he was able to deduce the distance to which the α-particle had approached the positively charged part of the atom in order to suffer such large deflections as were observed, and found the distances to be sub-atomic.

The periodic system of the elements assigns to each element a number denoting its place in the table called the atomic number. This was now identified by Mosely to be identical with the positive charge on the nucleus. The simplest nucleus is that of hydrogen having unit charge and is called the proton. The other charges are multiples of these but the chemical atomic weights of the various atoms are not exact multiples of the weight of a proton. The explanation was furnished by the work of J. J. Thomson on positive-ray parabolas and the refinement which Aston introduced by designing his mass-spectrograph. This work showed that the masses of the different atoms were really integral multiples of that of the proton, thus reviving Prout's hypothesis. The chemical atomic weights were shown to be different from integers because the chemical elements are mixtures of atoms of different mass but with the same charge. Such atoms occupy the same place in the periodic table and are called isotopes. The separation of isotopes is very difficult; but in the case of the most interesting isotope, *viz.*, the heavy isotope of hydrogen discovered by Urey (for which he obtained the Nobel Prize) has been separated, with the help of its most important compound: heavy water. G. Hertz has also succeeded in separating the isotopes of neon and of hydrogen by repeated diffusion through a large number of porcelain vessels connected to diffusion pumps. Prof. Born had seen his apparatus filling a large room and witnessed its working.

Starting from the nuclear model of the atom, Bohr assumed that the electron, *e.g.*, in the hydrogen atom was revolving round the nucleus but it could do so only at definite distances from the centre so that its angular momentum changed from one position to another by integral multiples of h—Planck's constant—and that the difference in the energy when an electron jumped from one orbit to another was radiated as a single quantum $h\nu$ of frequency ν. Bohr was thus able to explain Balmer's formula for the lines of hydrogen and to deduce the constant occurring in it with great accuracy. He elaborated his theory further by the correspondence consideration that in the limit, classical theory and quantum theory should lead

to the same result but there were a number of difficulties which were only removed by the Quantum Mechanics of Heisenberg and Schrödinger. According to this we no longer think of the electron as actually describing an orbit, but the orbits of the earlier theory with some modifications are the loci of the most probable positions of the electron. The quantum mechanics was also very successful in explaining how radioactive atoms send out quite by chance a particle now and then, though nobody can predict whether a particular atom is going to explode now or a hundred years hence. The explanation was offered by Gamow and by Gurney and Condon. The constituents of the nucleus have to overcome a large resistance due to their mutual attraction if they are to come out. According to classical ideas, they can never come out if their energy is less than that required to overcome this opposition while actually those that come out are shown by experiment to have an energy less than this. Taking the analogy of bodies within a crater wall, we see that they can fall outside the crater only if originally they were at a greater height. But if they were waves a certain fraction of the waves would pass through the wall as sound waves do, and if we assume the wall to become thinner at the top, waves passing near the top would penetrate easier. In a similar way the quantum mechanics associates the particles inside the nucleus with waves which have thinner barrier to pass through the larger of the energy particles and thus the fraction of these particles which comes out is the larger, the greater their energy. This is the explanation of the Geiger-Nuttall law in Radioactivity.

Further progress in our knowledge of the nucleus came from the work of Rutherford who bombarded Nitrogen with α-particles and showed that hydrogen was given out. Recent improvements in technique have enabled Cockroft and Walton and Lawrence to produce artificial missiles which disrupt a number of nuclei. Here again theoretical calculations by Gamow according to quantum mechanics showed first the possibility of breaking up the nucleus even with missiles having lower energy than the binding energy of the constituents of the nucleus, if the missile itself is caught by the nucleus.

The discovery of neutrons *i.e.*, uncharged particles of the same mass as the hydrogen nucleus (proton) by Curie and Joliot and Chadwick cleared up a number of difficulties associated with the previous assumption that nuclei consist of protons and electrons. These neutrons do not produce tracks in a cloud chamber and they cannot be stopped by large thicknesses of such heavy metals as lead. But peculiarly enough they are absorbed by light substances rich in protons such as paraffin, and the protons which they dislodge can then be studied by means of their tracks and yield information about the neutrons. Heisenberg has developed a general theory of nuclei assuming them to contain only protons and neutrons and assuming a general expression for their interaction. Further advance is to be sought in a satisfactory theory of β-decay. In course of trying to explain the fact that in β-decay electrons of all energies are sent out and not merely discontinuous groups, Pauli suggested that along with the electrons uncharged particles of very small mass called neutrinos are emitted along with the electrons, and Fermi has developed this theory to a large extent. Interesting experiments have been made at Cambridge to detect these neutrinos. They may possibly be capable of penetrating miles of lead.

Another discovery foreshadowed by theory is that of the positron. Dirac had propounded a theory of the electron which showed that positive particles of similar mass should exist. Examining the "showers" of particles produced by Cosmic radiations, by means of a Wilson chamber placed in a magnetic field, Anderson detected electron tracks curved in opposite ways. By placing a sheet of lead across the chamber and finding on which side the energy decreased resulting in greater curvature of the path, he was able to demonstrate that the particles producing both classes of tracks were moving in the same direction and therefore opposite curvature indicated opposite charge. This proved the existence of positrons and also showed that a γ-ray produces an electron-positron pair. Thus matter has been created out of radiation as definitely proved later by Curie and Joliot. The reverse of this, namely, the annihilation of an electron-positron pair resulting in high frequency γ-radiation has also been observed.

Lastly must be mentioned the discovery of artificial radioactivity by Curie and Joliot, for which they have recently obtained the Nobel Prize. These observations give fresh information about the stability of the nuclei. But just at the present moment the definite structure of the nucleus is not yet known and much further progress will have to be made before the question is finally settled. We must find an explanation, for example, for the spins of nuclei, the spin being an important property in itself, but of special interest to the audience owing to the fact that Prof. Venkatesachar and his collaborators were engaged in its investigation. Further the magnetic moments of nuclei have to be interpreted in terms of the moments of the neutron and the proton; the latter has been experimentally found by Stern to be 2.5/1840 Bohr Magnetons. However, said Prof. Born, this progress may be achieved in a short time, and with this expression of hope, he concluded his most interesting address which had kept a mixed audience of students and scientists spell-bound throughout the hour elapsed during its delivery.

T. S. S.

Properties, Characteristics and Uses of Stainless Steel.*

THE investigations on this important development of metallurgy during the last 25 years, and particularly after the war, have resulted in many brands of stainless steel, called by several names. It is, therefore, not surprising that Mr. Main should have found it difficult to give a single definition for stainless steels. The two varieties of this class of steel dealt with by the lecturer are really typical of this class. Now that there are several makes of almost the same kind of product, having practically the same chemical composition, it would perhaps be misleading to classify all of them under the same category. It would be better to name them by the chief characteristics which they possess such as acid-resisting, rust-free, heat-resisting, etc.

The chief characteristics of plain chromium steels largely used in the manufacture of cutlery have been dealt with in detail and attention is drawn to the prevailing belief that ordinary carbon steel gives greater hardness to the cutlery and retains it better than the stainless type. If stainless steel cutlery has to maintain the same reputation as plain carbon steel product and still be competitive with it, it would serve no practical purpose to improve hardness by adding other valuable elements and thus adding to the cost. It is a point for investigation if carbon itself could not be increased beyond the present limit of 0.35 per cent. keeping the chromium content round about 14 per cent. It is of course practically impossible to handle a product like the above with our present methods of heat treatment and new methods of working will have to be developed. This would incidentally help a larger use of the cheaper grades of high-carbon ferro-chrome.

There is no doubt that for decorative and household use the famous "18–8" variety is best suited. Here again the presence of a large quantity of nickel is making the product very expensive. The question whether an improved technique for the manufacture of stainless irons could be developed so that a cheaper substitute may be made available for the chrome-nickel type of stainless steel, deserves investigation.

Considerable work is at present being done in important Institutes of research with a view to determine the relative merits of different metals and alloys for containing foodstuffs. The author's statement that there is not the slightest fear of food contamination and consequent poisoning, in stainless steel vessels and that there is no anxiety on this score is very assuring.

The use of stainless steels in the chemical industries is perhaps much more extensive than in other fields. Almost all the important industries use this material in greater or smaller degree, and it is believed that the high initial cost paid for the stainless steel equipment is more than compensated by the saving due to absence of frequent repairs and renewals. It is hoped that in course of time some modified form of chrome-nickel stainless steel will be evolved which would resist the action of the two important acids, *viz.*, sulphuric and hydrochloric, which easily attack the present brands of stainless steel.

In the field of mechanical engineering the use of plain chromium steels is becoming more and more common. Most of the high pressure steam turbines have blades made of a special type of chromium-nickel steel. Pump impellers and parts of automobiles and aeroplanes are made of stainless steel. The stainless steel train referred to by the author is of special interest since the deterioration on ordinary steel trains due to corrosion is stated to be on the increase. Apart from the decrease in weight of the carriages, the absence of annual cleaning and painting and complete renewal perhaps once in about 12–15 years should make it worth while to take up a thorough investigation of the overall relative merits of the two types of rolling stock at least for fast express trains.

A reference is made to a series of new cheap alloy steels which resist corrosion better than the plain carbon steels, chiefly copper and copper chromium steels. But it is doubtful if any reasonably cheap steel could be produced which would be rust-free and at the same time capable of being rolled into the numerous sections used in structural Engineering.

A brief reference has been made to the manufacture of stainless steels, and the several manipulative processes required for finishing them. A passing mention may be made here of the new direct processes for manufacturing stainless steel. It is true that several of the present patents cannot be strictly called commercially successful, but one or two processes especially Wild's process, seems full of promise. The mechanical working of steel after the ingot stage has been receiving considerable attention and any improvement in the mechanical equipment handling this type of steel with a view to minimise rejections should be welcome. After all the demand for this type of special product is largely guided by the price at which it can be sold, and attempts must therefore be made in the direction of cheapening the cost of production during the several stages of manufacture.

The theory of protective film produced naturally on the steel, advanced by the author, is full of interest. The popular impression of stainless steels was that the stainless character is in the substance itself rather than due to any protective coating on the outside. The claim put forward by the manufacturers of stainless steel products that these products are superior to those having special coatings of chromium or nickel was largely based on this belief.

The several practical details given by the author in relation to cutlery steel, temper colours and the non-magnetic character of nickel steel, and the precautions that should be observed in working them should be very useful to the user of this class of steels. Reference to the recently discovered defect of intergranular corrosion when fabricating stainless steels and the special methods of overcoming it is also of practical value.

The future of stainless steel depends largely on the extent to which it can compete with its likely rivals in chemical industries and household utensils, these rivals being brass, bronze and

* "Properties, Characteristics and Uses of Stainless Steel," Lecture by S. A. Main, B.Sc., F.I.P., Royal Society of Arts, 1935, **83**, 672.

aluminium. The next step in the development of this class of steels should therefore be mainly in the direction of cheapening the cost of production. One method is to perfect the several practical details connected with the direct processes referred to above. These processes will involve the use of lower grades of chrome ore, thus conserving the richer chromium resources of the world for only highly specialised products. Just as the iron ores containing round about 30-35 per cent. of iron were considered 50 years ago as being quite uneconomical for conversion into iron, while now the same class of ore is largely used in blast furnaces in England and on the Continent, similarly the development of suitable methods for economical utilisation of large deposits of low grade chrome ores should prove of considerable help.

D. V. KRISHNA RAO.

Science Notes.

A Note on the Sapogenin from Soapnuts.—Dr. S. V. Shah, Rajaram College, Kolhapur, writes under date 16th November, 1935: "On referring to literature one finds that work on this sapogenin was begun by Winterstein and co-workers (Hoppe-Seyler's *Zeit. Physiol. Chem.*, 1911, **75**, 427; *Helv. Chim. Acta*, 1919, **2**, 198). But more recently W. A. Jacobs took up the same work (*J. Biol. Chem.*, 1925, **63**, 621; **64**, 379).

"According to Winterstein the sapogenin is a neutral optically inactive product having the molecular formula $C_{18}H_{28}O_{3}$, molecular weight 280, and melting point 319-320°. Jacobs described it to be dextro-rotatory [$(\alpha)_D$, 81°; l=1.009 in pyridine] and acidic in nature as it yields a sodium salt, and to have the molecular formula $C_{31}H_{50}O_4$. He thus found it to be exactly identical with hederagenin of Van der Haar (*Ber.*, 1921, **54**, 3142). For a moment one could argue that Winterstein's product was impure and as suspected by him was a mixture and the reduced optical activity was not observed in dilute solution.

"Further on treatment with concentrated nitric acid, Winterstein obtained from the sapogenin 1:5-dinitro- and 1:8-dinitro-naphthalenes. This appears more in support of Winterstein's than Jacobs' formula, as the removal of 21 carbon atoms from the molecule by nitric acid is rather unexpected. Windaus and Shah, Windaus and Linsert (*Zeit. Physiol. Chem.*, 1926, **151**, 86; 1925, **147**, 275) could not remove by this method more than five carbon atoms from oxydigitogenic, digitogenic and gitogenic acids. On the other hand, a degradation by eight carbon atoms (from 18 to 10) accepting Winterstein's formula appears more probable also according to recent work. Tschesche (*Ber.*, 1935, **1393**, 1412) has shown that the skeletons of digitogenin gitogenin and tigogenin have a side chain of eight carbon atoms in addition to four hydrogenated rings. In the case of these genins it is this side-chain which is attacked by nitric acid with the removal of five carbon atoms. By analogy, it is more probable, that, in the case of the soapnut sapogenin, eight carbon atoms would be removed by nitric acid instead of twenty-one carbon atoms thus supporting more the Winterstein's than Jacobs' formula for the sapogenin."

An Iron Horse from the Central Provinces.—Among the exhibits that were shown and commented upon at the ordinary monthly meeting of the Asiatic Society of Bengal, held on Monday, the 2nd December, was an iron horse. This exhibit which was shown by Sir Lewis Fermor "was obtained some 32 years ago from the top of a hill of manganese-ore in the Chhindwara district. The manganese-ore cropped out in large black masses, which in one place had been daubed with red paint and treated as a village god. Lying about were a number of clay horses and an iron one. This hill has since been worked as a manganese mine, and is now represented by a large hole in the ground.

The interest of this specimen is perhaps threefold. In the first place it has been exposed to the moist air of Calcutta for over 31 years, without any appearance of rust, from which one can deduce that it is made of very pure iron, as in the case of the iron pillar at Delhi. Its age, of course, is unknown.

The second point of interest is that it must be regarded as an example of primitive art. It is made mainly from three pieces of iron—one piece forming the head, the body and the tail, another piece the front pair of legs, and a third piece the hind pair. The way in which the pairs of legs are bent over the body provides a representation of a saddle. In addition, there are two extra small pieces of iron welded on to form the ears. Two touches of vermilion on the head suggest the eyes. The horse is so constructed as to be unstable when standing on its four feet, but to be stable standing on a tripod consisting of its hind legs and tail. It is a little over 7 inches long, and is in consequence less than one hand high.

I have shown this horse on occasion to many people, and no one appears to have seen a similar horse before, but—and this is the third point of interest—it has been suggested to me that it should be compared with the horses that are offered to the Southern Indian village deity known as *Iyenar*—a beneficent male deity, who is regarded as the village watchman and whose duty is to patrol the village and fields at night. If this suggestion is correct, it is an indication of the extension of this South Indian deity as far north as the Chhindwara district in the Central Provinces. An account of *Iyenar* is given in Bishop Whitehead's "Village Gods of Southern India". These village gods, according to Bishop Whitehead, date from before the Aryan invasion and must be regarded as Dravidian deities. The Gonds of the Central Provinces are, of course, Dravidians, and it is not, therefore, surprising that worship of this deity *Iyenar* may have extended to the Central Provinces. I was not, however, given any name for the deity, and have no knowledge whether there is any local name for *Iyenar* in the Central Provinces."

The Food of 'Peking Man'.—An answer to the interesting question "what constituted the food of the earliest man-like animals?" has been provided by the painstaking excavations of the bone-bearing masses of breccia conducted by the members of the National Geological Survey of China. The living quarters of the Peking man, *Sinanthropus pekingensis*, dating back to the beginning of Pleistacene or Ice Age, have been recently unearthed, in which are found, in addition to the skulls and human teeth of the oldest inhabitants, stone implements, hearths and uneaten fragments of food. These afford evidence regarding the dietary habits of the early man (*cf.*, "The food of Peking man," *News Service Bulletin, Carnegie Institute of Washington*, 1935, 3, No. 25). Crudely fashioned flakes of quartz served to cut and scrape. Several feet of ashes piled against the walls of the cave show that the early man knew the use of fire. In the ashes have been discovered bits of incompletely burnt wood and abundant fragments of charred bones. The Peking man must have used game animals for his food. Thousands of fragments of shells of hackberry seeds occurring in the breccia, constitute the earliest record of the use of plant food by the prehistoric man. These berries were perhaps used to flavour the meat, as is being done by the natives of the South-West of Armenia to this day. We have thus a good record of the feeding habits of the Peking man preserved through the obscurity of over a million years.

* * *

Timber Research. (His Majesty's Stationery Office, Price 1*s*. 6*d*.).—The Report of the Forest Products Research Board for the Year 1934 gives an account of the progress made during the year in the investigation of the many and varied problems concerned with the efficient utilisation of timber. The work covers a wide field and involves the study of the physical, mechanical and seasoning properties and the working qualities of timbers, and the control of fungal and insect pests. The Report cannot fail to interest those concerned with the handling and use of timber, research into which means large economies to the timber-using industries and professions.

* * *

Indian Central Cotton Committee, November 1935.—(1) DEVELOPMENT OF COTTON CULTIVATION IN SIND:—*Botanical Work*.—Replicated field-scale trials of the improved Sind American types 289 F–1, now known as 'Sind Sudhar' cotton, 285 F–2 and 4F–98, together with the improved *deshi* type 27 W.N. were conducted both at Sakrand and at the Government Seed Farm, Mirpurkhas. Progress was made in the selection work with Punjab-American cottons and more extensive trials with a new and promising strain namely 289 F–20 were conducted at Mirpurkhas. African cotton types A 12 and U 4, were obtained and similarly tested. Bulk samples of imported Uganda, Morad (Egyptian) and Sudan cottons are also being studied by the staff of the Botanical Section and put to further tests. *Physiological Investigations*.—The study of factors responsible for 'red leaf' blight on American and Egyptian cottons grown in Sind with the object of obtaining information regarding the possibility of control of this disease, or the breeding of resistant types has been continued. The Indian Central Cotton Committee in conjunction with the Imperial Council of Agricultural Research, made a grant of Rs. 16,030 in January 1933, for a period of three and a half years for an enquiry into the cost of production of cotton and sugarcane with their rotating crops in Sind. *Sind Cotton Extension Scheme*.—The activities covered by this scheme. financed by the Indian Central Cotton Committee are being pursued in two Sections, one in the Left Bank areas and the other in the Right Bank areas of the River Indus. In the Left Bank Section, tests carried on with regard to the respective yields and suitability for extension of different varieties of cotton, in Thar Parkar, Nawabshah and Hyderabad Districts have demonstrated the high yielding capacity of 289 F–1, 4 F–98 and (*Deshi*) 27 W. N. Plots for the cultivation of these varieties were laid down at three centres and the best methods of growing them were shown to the cultivators. In the Right Bank Section—hitherto a non-cotton growing area—the work on thirty-five demonstration plots in the Dadu, Larkhana and Sukkar Districts, brought promising results from the growing of 4 F–98, 1500 acres were cultivated under cotton in *Kharif* season of 1933 and there was every indication of a further extension of cotton cultivation in this area. Seed of improved varieties of cotton sufficient for the cultivation of 4,000 acres was distributed and intensive propaganda was conducted in the districts to induce Zamindars to take up cotton cultivation.

During the year 1935–36 the cotton area on the Right Bank is over 16,000 acres which is about four times of what it was in the previous year.

The interesting point during the year has been that the area has been mostly under the American variety and the *deshi* has been eliminated from the tract.

(2) FIBRE-MATURITY IN RELATION TO FIBRE AND YARN CHARACTERISTICS OF INDIAN COTTONS: The exact relationships between the maturity count of cotton and its fibre properties on the one hand and the number of knotted and tangled fibres, technically known as 'neps' in the yarn, on the other, have been investigated by Dr. Nazir Ahmad and Mr. Amar Nath Gulati. The results showed that the variety known as *C.A*. 9 tops the list, having over 80 per cent. of fibres fully mature, while in *Goghari E*. 2, which comes at the bottom of the list, only 14 per cent. of mature fibres were observed. It was also found that cottons like *Mollisoni* produced practically 'nep' free yarns while type 413 contained as many as 19 'neps' per yard and could only be described as exceedingly neppy. The investigators then proceeded to study the influence of such factors as season, locality of growth, heredity, etc., on the degree of fibre maturity of a cotton and the relationship of the latter with fibre properties and yarn characteristics.

As a result of these investigations it is concluded that (*a*) Mature fibres are on the whole stronger than either half-mature or immature fibres. (*b*) Percentage of immature hairs in a cotton has an important bearing on the formation of 'neps' in yarns and cotton comprising a high percentage of immature hairs are likely to give rise to yarns containing proportionately large number of 'neps'. (*c*) There is no

significant relation between maturity and staple length, but detailed analysis showed that a majority of short stapled cotton possessed high percentages of mature fibres while a majority of comparatively long stapled cottons are characterised by low percentages of mature hairs. (*d*) On a detailed analysis it was found that in medium and long stapled cottons higher fibre-maturity was usually associated with better spinning performance, while in short stapled cottons the reverse was the case.

These results are embodied in Bulletin No. 20, issued by the Technological Laboratory of the Indian Central Cotton Committee (Price as. 8). The Bulletin describes the technical details of the tests employed in the investigation and is illustrated with charts and interesting photomicrographs.

Oxidation and Scaling of Heated Solid Metals. (His Majesty's Stationery Office. Price 2*s*. 6*d*. net).—This volume issued by the Department of Scientific and Industrial Research contains a full critical review by acknowledged experts of the recent work on oxidation and scaling of heated solid metals summarising existing information and drawing attention to problems requiring further research. It is mainly concerned with the mechanism and rate of oxidation and properties of oxide layers, but it also contains sections describing the practical effects of oxidation and scaling and the methods of prevention to be employed.

* * *

New Applications for Superphosphate.—The Research Institute for Fertilisers and Insectifungicides has recently established that double superphosphate from apatite and thermic phosphoric acid with a total content of 50·17 per cent. of phosphoric acid gives positive results when used for the dry treatment of millet and wheat seed against smut. Six grams of superphosphate per kg. of seed proved sufficient. Field experiments have shown that millet and wheat seeds treated in this way did not suffer from smut, whereas on the check plots sown from untreated seeds the smut infestation was as much as 30 per cent. The germination rate of wheat was somewhat reduced, whereas millet retained its germination rate.—(*Industrial and Eng. Chem.*, 1935, **13**, 406.)

* * *

Harrison's Chronometers at the Science Museum.—The Science Museum, South Kensington, has recently acquired on loan, by courtesy of the Admiralty, all four of the pioneer marine time-keepers made by John Harrison between 1729 and 1759. With these instruments Harrison was the first to show that it was possible to construct a portable time-keeper which would keep sufficiently accurate time at sea to be of use in determining a vessel's longitude, and thus solved the problem of "finding the longitude", which had baffled men of science and inventors for over 200 years. Harrison's instruments were the first balance-wheel time-keepers to embody any kind of compensation for the effects of change of temperature. In all his four instruments compensation is provided by varying the effective length of the balance-spring, the mechanical details varying in the different individuals. The first three time-keepers are large clocks each weighing over 50 lbs., but the fourth is much smaller, being in the form of a large watch a little above 5 ins. in diameter. The third and fourth instruments, in particular, are of great complexity and were obsolete even in Harrison's life-time, for after he had shown the possibility of constructing an accurate marine time-keeper other makers were able to devise simpler means of achieving the same ends. All four of Harrison's instruments have been cleaned, repaired and put into working order by Lt.-Commander R. T. Gould, and they are now on exhibition in the Museum in working condition.—(*J. of Sci. Instruments*, 1935, **12**, 339.)

* * *

Radio Feeler.—A radio device reputed to enable a ship to "feel" its way through fog hasbeen tested on the French "*Normande*". A radio beam of a wave-length of 16 centimetres describes an arc of 45 degrees in the direction of the ship's travel and if the beam is intercepted by any obstacle in its path, a loud speaker announces the fact to officers on the bridge. It is stated that objects have been detected at distances up to four miles.—(*Wireless World*, 1935, **37**, 491.)

* * *

Plasticised Sulphur in Road Construction.—Experiments at the Mellon Institute indicate that plasticised sulphur which may be made by reacting sulphur with organic sulphides, polysulphides or polymers of these, can be used successfully as a binder for brick in road construction. Test panels subjected to heat showed no signs of the material exuding at temperatures well above the range met in pavements. A test road will be constructed by the State of Ohio next Spring. Plasticised sulphur gives a very fluid material at the temperature of application which is about 300° F.—(*Canadian Chemist and Metallurgist*, 1935, **19**, 279-35.)

* * *

A New Organic Reagent.—Rhenium, which was recently discovered, is being manufactured in Germany on a commercial basis, as it appears to have some industrial uses. Many attempts have been made to evolve a method for the analysis of the metal, but so far without success. It is now reported (*Chemical Age*, 1935, **33**, 441) that a new radical, tetraphenylarsonium, prepared from triphenyl arsine has been discovered by Bucke and Monroe, which can be successfully employed in the determination of Rhenium. Tetraphenylarsonium-per-rhenate is a crystalline and extremely insoluble precipitate with a high molecular weight and hence is well suited to the precipitation of this metal and its separation from other metals.

A very sensitive volumetric method for the estimation of iodine as well as the arsonium base itself, can be worked up by utilising tetraphenylarsonium chloride which forms an extremely insoluble periodate. As this chloride forms insoluble compounds with chlorides of cadmium, zinc, antimony, tin, mercury, quadrivalent lead, bismuth, platinum, gold, it can be successfully employed for the quantitative analysis of these metals. Very rapid estimations of zinc, cadmium, mercury, platinum and gold have been made by making use of this fact, with a high degree of accuracy.

American Stratosphere Balloon, Explorer II.—A notable achievement falls to the credit of Captain A. W. Stevens and Earl A. Anderson of the U.S. Army Air Corps, who, according to the reports in the daily press, have successfully piloted their stratosphere balloon up to the record height of 74,000 feet. The previous record was held by the ill-fated Russian balloon *Osoaviakhim* which probably reached a height of 72,000 feet on January 30, 1934. After the first set-back of last July, when the top of *Explorer* II burst and released 375,000 cubic feet of helium, another occurred on Monday, November 11, when a 20 feet rent in the envelope produced during its inflation, had to be repaired at the last moment. The ascent was made at 7 a.m. from a point eleven miles west of Rapid City, and a safe landing was made in the evening at White Lake, South Dakota. Capt. Stevens reported by wireless that at his maximum height the external temperature was — 55°C., the cosmic ray intensity 150 times at earth's surface and that the sky had become a jet black awning.—(*Nature*, 1935, **136**, 786.)

* * *

Animal Experiments in the Investigation of Diseases.—The achievements of Louis Pasteur and Robert Koch have established the importance of animal experiments in the study of the cause and cure of diseases. In a valuable article published in *Research and Progress* (1935, 1, 188) Professor Paul Uhlenhuth of the University of Freiburg, has furnished a brief account of the more recent researches on the nature of the diseases and the biology of the germs causing them. Weils disease, or infectious jaundice which was so prevalent during the Great War, is caused by *Spirochæta icterohæmorrhagiæ*; the experiments leading to this discovery were carried out on guinea-pigs. The deficiency diseases are all studied through animal experiments. Not only are animals used for discovering the causal agencies but also as means of diagnosing difficult cases of infectious diseases; mouse is used in the diagnosis of anthrax and tetanus and guinea-pig for the diagnosis of glanders and particularly of tuberculosis. Experiments with rats and guinea-pigs are officially prescribed for diagnosing small-pox and rabies. Another way in which animals have proved valuable in diagnosing diseases is in the agglutinin and bacteriolytic reactions. The precipitin test offers an extremely sensitive and valuable test in the identification of specific proteins and finds several applications, as for instance in the detection of adulteration of foods. The same reaction has served to establish the blood relation of the horse and the donkey, of the dog and the fox and of the man and the ape. The remedial and protective sera used in combating diseases are obtained from animals; the examples of such are found in antidiphtheritic and antitetanus sera. Animals also give the important vaccines—those against small-pox, rabies, etc. Experiments with animals form the basis of chemo-therapy and have assisted in the discovery of arsenical preparations for syphilis, antimony preparations for kalaazar etc. Chemotherapeutic research through experiments with animals has ultimate possibilities of discovering remedies for the so-called incurable diseases such as, cancer, and bacterial infections (*sepsis, typhus*, etc.)

World Petroleum Congress.—The Association Francaise des Techniciens du Petrolu have issued an invitation to hold the World Petroleum Congress, 2nd Session, in Paris. in June or July 1937. The Council of the Institution of Petroleum Technologists have accepted the invitation. The task of organising will devolve on the French Association but the Council of the Institute of Petroleum Technologists will remain in close touch with the arrangements.

* * *

Third World Power Conference.—It is announced that the Third World Power Conference will be held in Washington, U. S. A., from September 7 to 12, 1936. The general subject to be discussed at the Conference is the National Power Economy. The 2nd Congress of the International Commission on Large Dams of the World Power Conference will be held in Washington at the same time.

* * *

12th Conference of International Union of Chemistry.—The Executive Committee have changed the opening date of the Conference to Sunday, August 16, 1936, and will close on Saturday, August 22. The conference will be held in Luzern. An excursion to Zurich will be arranged on August 19. All communications are to be addressed to Fr. Fichter, Laboratorium des Kantons-Chemikers, Vonmattltrase, 16, Luzern, Switzerland.

* * *

The All-India Medical Research Workers' Conference was held at Calcutta during the first week of this month. Major-General Sir Francis Connor, Officiating Director-General of Medical Services, opened the Conference.

* * *

The Fourth All-India Industrial Exhibition will be held in Delhi, from February 29th, 1936.

* * *

Broadcasting in India.—A Radio Exhibition was held in Bombay on 9th December. Mr. Lionel Fieldon, Controllor of Broadcasting in India, opened the Exhibition. In the course of his speech, Mr. Fieldon said that the Government hoped to call a Conference of Representatives of States and Provinces, to discuss the future development of broadcasting. Dealing with the future, he said that "broadcasting was the gift of science to the people which, if used, with intelligence and impartiality, would infuse in the people, the spirit of good-will and mutual understanding and be a bridge to the millennium."

* * *

The John Fritz Gold Medal for 1936 has been awarded to Prof. William Frederick Durand of the Stanford University. Prof. Durand is an authority in hydro-dynamic and æro-dynamic science and in its practical application, he is an outstanding leader in research and in Engineering Education. It may be mentioned that this medal will be awarded each year for 'notable scientific or industrial achievement'.

* * *

Mr. T. H. Ritchie, M.A., B.Sc., Director of Agriculture, Central Provinces, has been appointed Director of Agriculture, U. P. Mr. T. C. McDougall, M.A., B.Sc., I.A.S., succeeded Mr. Ritchie as Director of Agriculture, C.P.

We are glad to announce that Dr. Subrahmanyan Chandrasekhar, Fellow of the Trinity College, Cambridge, has been appointed Lecturer in Cosmic Physics at Harvard University.

* * *

Lieut.-Col. R. N. Chopra, I.M.S., has been appointed Honorary Physician to His Majesty the King, in succession to Major-General Sir Robert McCarrison, retired. Lieut.-Col. Chopra has been promoted to the rank of Brevet Colonel.

* * *

The honorary degree of Ph.D., has been conferred on Dewan Bahadur L. K. Ananthakrishna Iyer by the Breslau University.

* * *

The Degree of Doctor of Science (D.Sc.) has been conferred on Dr. S. V. Desai, by the Senate of the London University.

* * *

Doctor Sir Upendra Nath Brahmachari has been re-appointed by the Senate of the Calcutta University to the Court of the Indian Institute of Science, Bangalore, for the period 1936–40.

* * *

The Imperial Bureau of Soil Science, has recently issued a complete "Bibliography of Soil Science, Fertilizers and General Agronomy" covering the whole scientific literature of the world on soil and allied sciences during 1931–34. This extremely comprehensive Bibliography gives the reference to practically every paper published during that period on the different branches of soil science, both pure and applied, on the use of fertilisers, on the cultivation of all the chief economic crops (over 140, including forests, are listed in the index) and on plant diseases in relation to soils. The references are arranged by subjects according to the Universal Decimal Classification, which is adequately explained in the Preface. The volume also contains an index to the Decimal Classification, an alphabetical cross-index to every subject on which the papers listed have been written, an author index containing over 4,000 names, and a list of the abbreviations used, and the full titles and places of issue (where known) of 800 journals, etc., from which the references in the Bibliography have been taken.

The Bibliography has been compiled from the references which appeared in the first 41 issues of the Bureau's monthly lists of *Publications Relating to Soils and Fertilisers*. An unusual feature is that the literature of almost every country has been covered equally well, thanks to the exceptional facilities for procuring foreign periodicals which the Soil Bureau enjoys. Considering its scope and the amount of information it contains, the book has been made remarkably compact, without detriment to its readability. It should be a most valuable reference book to every agricultural scientist whose work is, in any way, connected with the soil. The Bureau intends to issue further similar bibliographies at intervals of 3–4 years, and in this way gradually to build up a complete reference library to the whole literature of the soil over an extended period of time.

Crown Octavo, pp. 504. Bound in cloth, with gold lettering, price 25/- net; post free, from the Imperial Bureau of Soil Science, Harpenden, England.

Announcements.

The Society for the Study and Promotion of Family Hygiene.—A new organisation whose aim is, broadly, to help in increasing happiness in the marital and family relationships and ensuring a general improvement of the human races, has recently been started at Bombay. The Society aims to provide facilities for research and proposes to (1) grant scholarships and endowments for stimulating and organising research, (2) publish reports, leaflets, dealing with topics connected with family, marriage and allied subjects in their social and biological aspects, (3) organise propaganda for the introduction of sex education in schools and other teaching institutions, (4) start consultation centres and contraceptive clinics for promoting family and marriage hygiene, (5) hold periodical conferences and arrange lectures, (6) make available to members, a library containing selected scientific books, (7) collect and collate manuscripts, press cuttings, etc., (8) build up a museum for education purposes, etc., etc. The promoters expect that the Society would either expand into an international organisation in due course, or would be affiliated with similar organisations in other parts of the world.

An all-India Council and the different Provincial Councils are under formation. The membership is open to adults of both sexes who are in sympathy with the objects of the Society. The annual subscription will be Rs. 10 for members and Rs. 15 for Fellows. Further information regarding the Society can be obtained from the General Secretary, Society for the Study and Promotion of Family Hygiene, Kodak House, Hornby Road, Fort, Bombay.

* * *

The First All-India Obstetric and Gynæcological Congress, 1936.—Under the joint auspices of the Bombay Obstetric and Gynæcological Society and the Obstetric and Gynæcological Society of Southern India, the first All-India Obstetric and Gynæcological Congress will be held at Madras on the 2nd, 3rd and 4th January, 1936. Subjects to be considered will be discussed under three sections, *viz.*, Obstetric section, Gynæcological section and Maternity and Child-Welfare section. A scientific exhibition of scientific appliances, foodstuffs, drugs and scientific books, will be held during the session. All communications should be addressed to the President of the Obstetric and Gynæcological Society of Southern India, Government Hospital for Women and Children, Egmore, Madras.

* * *

First Indian Population Conference.—The Conference will be held on January 27–28, in Lucknow, with Sir U. N. Brahmachari as General President. Prof. Radha Kamal Mukherjee, is the convener of the Conference. Discussions on problems of social biology and hygiene, vital statistics, production and population trends in various Provinces, etc., will be held during the Conference.

Researches on Desert Plants.

THE peninsula of Baja (or lower) California, by reason of its extreme aridity and isolation has developed many species of plants peculiar to it. Dr. Forrest Shreve of the Desert Laboratory of Carnegie Institute of Washington recently led an expedition into these regions to investigate (1) the influence of extreme aridity and of the proximity of the sea on the plant life, and (2) the contrasts between the floras of the Gulf and Pacific slopes and the differences between the same latitudes on the peninsula and the main land. The study of the flora itself is full of significance "with the long history of its origin from its ancestral stock, its migratory movements, and its constant need of either finding just the right life condition, or else adjusting itself to the one that it is able to find." An account of the results of this expedition is published in the *News Service Bulletin, Carnegie Institute of Washington*, 1935, **111, No. 26.**

In 1934 and for several previous years the area did not have any rain. In the beginning of 1935, there was rain for several weeks, and the larger plants were in leaf and blossom, and the ground was covered with a carpet of short-lived anuals. Most of the plants that impart character to the landscape of Baja California, are either found nowhere else or occur sparingly in Sonora. In sharp contrast with the plants that live in rainy climates where their only struggle is with one another, the desert plants do not interfere with other plants and their struggle is with the environment. This results in the development of a large number of types each of which is capable of winning the battle with the environment in a different way. The most outstanding plant in Baja California is 'Cirio' (*Idria columnaris*). Next comes 'torote' (*Pachycormus discolor*), the giant 'yucca' (*Yucca valida*), the large century plant (*Agare goldmaniana*), the giant cactus (*Pachycereus prongleü*), the 'Ocotolla' (*Fouquieria peninsularis*) and the 'creeping devil' (*Machærocereus eruca*). The cirio and the 3 species of ocotillo have developed a mechanism of withstanding desert conditions which is unlike that of cacti or, for that matter, any other plant in the world. The leaves which make the food materials necessary for the plant, fall off after the rainy season and the stems are protected from desiccation by horny layers of tissue impregnated with resin just beneath the barks.

Academies and Societies.

Indian Academy of Sciences:

November 1935. SECTION A.—S. SIDDIQUI AND Z. AHMAD: *Alkaloids from the Seeds of* Cassia absus, *Linn.*—Two water soluble isomeric quarternary bases, to be called chaksine and iso-chaksine have been isolated. S. SIDDIQUI: *Studies in the Conessine Series. Part I.—Isomerisation of Conessine and its Nor-Bases.*—The isomerisation effected through the action of concentrated sulphuric acid on the corresponding bases in the cold has been studied. Iso-conessine is about thrice as potent as conessine. R. P. DODWADMATH AND T. S. WHEELER: *Studies in the Chemistry of Chalcones and Chalcone-Oxides. I. Phenyl-(3·4-methylene-dioxy-styryl)-ketone.*—The effects of presence of other groups in the nuclei on the reactivity of chalcones and chalcone-oxides are reported. R. ANANTHAKRISHNAN: *Some New Features in the Raman Spectra of Carbon and Silicon Tetrachlorides.*—Octaves of fundamental frequencies and their differential tones are recorded. C. S. VENKATESWARAN: *The Fluorescence of Ruby, Sapphire and Emerald.*—The photo-luminescence of the natural crystals has been studied at room-temperature and a number of new bands are observed. T. S. WHEELER: *On the Theory of Liquids–V.*—A summarised presentation of the theory developed in the previous papers of this series. S. BHAGAVANTAM: *Raman Spectrum of Deuterium: II.—Intensity and Polarisation Characters.*—The results when compared with those calculated from the theory of rotational Raman scattering due to Manneback, show satisfactory agreement. P. S. REGE AND T. S. WHEELER: *A Study of the Benzoin Reaction-IV.—The Kinetics of the Benzoin Reaction in the Presence of Organic Solvents.*—With inert solvents the heterogeneous reaction is unaffected, but the homogenous reaction is decelerated. The action of hydroxy compounds is complicated, but on the whole, they accelerate the reaction. K. NEELAKANTAM, T. R. SESHADRI AND R. H. RAMACHANDRA RAO: *Pigments of Cotton Flowers.—Part II.—Uppam* (Gossypium herbaceum).—The main components are *gossypitrin and quercetin.*—A new glucosidic pigment and a small quantity of gossypetin have also been isolated. S. PARTHASARATHY: *Determination of Ultrasonic Velocity in 52 Organic Liquids.*—The velocity depends upon chemical constitution. The adiabatic compressibilities of all the liquids have also been calculated. A. N. KAPPANNA: *Kinetics of the Reaction between α-Brompropionate and Silver Ions.—A Heterogeneous Reaction taking place on the Surface of Silver Bromide.* S. W. CHINCHALKAR: *Magnetic Birefringence in Solutions of Organic Substances. Part I.*—Aromatic hydrocarbons containing two or more benzene rings have been studied.

November 1935. SECTION B.—MAKUND BEHARI LAL: *On the Morphology of a New Species of Monostome of the Genus* Notocotylus *Diesing*, 1839.—Specimens of monostomes have been described as a new species of the genus *Notocotylus*. A. C. JOSHI: *Secondary Thickening in the Stem and Root of* Stellera Chamæjasmæ *Linn.*—The anatomy of the stem and root of *Stellera Chamæjasmæ*, a member of the family Thymelæceæ, has been described. B. N. SINGH AND K. KUMAR: *An Analysis of the Influence of Season on Photosynthesis in the Tropics.*—Leaves adopt their structure and function according to the intensity of external factors, and the specific adoptability is mainly brought about by suitable changes in the internal factors investigated. MAKUND BEHARI LAL: *A Review of the Genus,* Notocotylus, *with Description of a New Trematode Parasite of* Mareca penelope *from Lucknow.*—A new form belonging to the genus *Hindia*, but differing from the known species of the genus in the number and arrangement of the ventral glands, the arrangement of the uterine coils and the anterior extent of the vitellaria, has been described. ALBERTO CARLOS GERMANO DA SILVA CORREIA: *The Marathas of Portuguese India.*—From an anthropometric point of view, the Marathas do not constitute a race, nor can they be considered as belonging to an only caste, though the majority of them may belong to the *chatria*. FROILANO DE MELLO: *New Hæmoproteids of Some Indian Birds.*—New species of hæmoproteids have been recorded. L. B. KAJALE: *The Female Gametophyte of* Alternanthera sessilis *R. Br.* A. C. JOSHI AND J. VENKATESWARLU: *Embryological Studies in the Lythraceæ. I.* Lawsonia inermis *Linn.*—The development of the normal 8-nucleate embryo-sac, the double and triple embryo-sacs and degenerations in the embryo-sac are described.

The U. P. Academy of Sciences:

September 1935. B. L. GULATEE: *On the Subterranean Mass-Anomalies in India.*—From the isostatic gravity anomalies in India, a distribution of mass anomalies expressed as a coating of normal crustal density in the reference surface has been determined. S. SUBRAMANIAN: *The Closure Property of Three Curves.* G. R. TOSHNIWAL AND B. D. PANT: *Measurement of Ionisation of the Kennelly-Heaviside Layer at Allahabad.*—The ionisation of the E region has been found in the month of April. The morning critical frequency was in the neighbourhood of 3.1 Mc./sec. at 8 A.M. The maximum critical frequency of 4.6 Mc./sec. was observed on the 18th April during the so-called "evening concentration". R. N. GHOSH AND L. P. VERMA: *On the Application of Heaviside's Operational Methods to the Solution of the Pianoforte Problem.* HRISHIKESHA TRIVEDI: *The Absorption Spectra of the Vapours of the Mono-Oxides of Copper, Iron, Nickel and Cobalt and the Determination of their Heats of Sublimation.* HRISHIKESHA TRIVEDI: *The Absorption Spectra of the Vapours of the Mono-Sulphides of Iron, Nickel, Cobalt and Copper and the Determination of their Heats of Sublimation.* S. S. JOSHI AND K. P. N. PANNIKAR: *The Variations of Viscosity during the Coagulation of Colloidal Aluminium Hydroxide by Potassium Chloride Solutions.*—The Progress of Coagulation at lowest concentrations of the electrolyte is sensibly discontinuous in the beginning. S. M. MEHTA: *Effect of Temperature on Borax Solutions in the Presence of Polyhydric Substances and Organic Acids.* RADHA RAMAN AGARWAL AND SIKHIBHUSHAN DUTT: *Chemical Examination of the Bark of* Terminalia Arjuna *Bedd. Part I.—The Isolation of Arjunin.*—An acidic principle, "arjunin" has been isolated, m.p. 192° C., $C_{26}H_{32}O_{11}$. SIKHIBHUSHAN DUTT: *Chemical Examination of* Glycosmis Pentaphylla *and the Constitution and Synthesis of its Active Principles.*—"Glycosmin" which is a crystalline glucoside

has been found to be a veratroyl derivative of salicin. N. R. DHAR AND S. K. MUKHERJEE: *Further Experiments on the Fixation of Atmospheric Nitrogen in the Soil and the Utilisation of Molasses as a Fertiliser.*—Molasses used as a manure, increases the yield of sugarcane to the extent of 36 per cent. M. B. MIRZA: Physaloptera Achari *N.Sp. from* Calotes versicolor *with a Short Note on Abnormalities in the Genus* Physaloptera.—A number of worms obtained from the stomach, small and large intestines, of *Calotes versicolor* found in Hyderabad, Deccan, has been described. HAR DAYAL SRIVASTAVA: *Studies on the Family* Heterophydae *Odhner*, 1911. *Part II.*—"*Four New Parasites of the Genus* Haplorchis *Looss*, 1899," *From Indian Fresh-Water Fishes with a Revision of the Genus.* B. P. PANDE: *Contributions to the Digenetic Trematodes of the Microchiroptera of Northern India. Part II.—Studies on the Genus* Lecithodendrium *Looss.* H. R. MEHRA: *New Trematodes of the Family Lecithodendriidæ Odhner*, 1911, *with a Discussion on the Classification of the Family.*—The account of a new genus *Exotidendrium* from the Indian gharial *Gavialis gangeticis*, and two new species of the genus *Eumegacetes* Looss from an Ashy Swallow-Shrike is given.

31*st October* 1935. S. C. DAMLE: *A Note on Sir Shah Muhammad Sulaiman's New Theory of Relativity.*—The degrees of accuracy of the two differential equations of motion obtained by Sir M. Sulaiman in Section V (Chapter I) of his theory dealing with Planetary Orbit were different. To maintain the same degree of accuracy, in both equations, the term containing the first differential coefficient of the distance from the centre should be retained in the first of the equations. When this term is retained in the first equation and other corrections introduced in the second, the value obtained for the rotation of the perihelion of mercury in one complete revolution is numerically one-sixth of the usually accepted value and in the opposite direction. N. R. DHAR AND S. K. MUKERJEE: *Use of Molasses inthe Reclamation of Alkali and Usar Lands.*—Reclamation of alkali soils is possible by the application of Molasses to the extent of 90–360 maunds per acre. Crops have been raised on such reclaimed soils with good yields. N. R. DHAR AND S. P. TANDON: *Influence of Temperature on the Fixation of Nitrogen by Azotobacter.*—Nitrogen fixation by Azotobacter takes place best at 35°C.; sunlight and azotobacter are the two potent agencies which serve to meet nitrogen requirements of tropical soils. A. M. D'ROZARIO: *On Two New* Xiphidiocercaria *from the Common Fresh-Water Snail,* Indoplanorbis exustus (*Deshayes*) *of the Northern India.*

5*th November* 1935. S. PRADHAN: *The Genetalia and Their Role in Copulation in* Epilachna indica (*Coccinellidæ: coleoptera*) *with a Discussion on the Morphology of the Genetalia in the Family.*—The structure, disposition and the mode of working of the muscles of the male and female genetalia of *Epilachna indica* were described. H. TRIVEDI: *The Absorption Spectrum of Hydrogen Bromide Molecule and its Upper Unstable State.*—An experimental verification of the author's theory of continuous absorption of a diatomic molecule by means of which it is possible to deduce the nature of the repulsive state. V. V. NARLIKAR AND D. N. MOGHE: *A Note on a General Line-Element.* D. N. MOGHE AND R. V. SASTRY: *The Field of a Non-Static Spherical Condensation.* SATYENDRA RAY: *The First Universal Principle of Sulaiman.* SATYENDRA RAY: *On Two Mutually Contradictory Interpretations of Einstein's Line-element by Sulaiman.* K. L. GUPTA: *On the Convergence and the Summability of the Conjugate Series of the Derived Fourier Series.* S. M. SANE AND A. B. SEN: *On Some Toluen Sulphonyl Esters of Phenols.* M. RAMAN NAYAR: *Variation of Physical Properties with Change in Concentration of Iodic Acid Solution.* UMAKANT SHUKLA: *Necessary and Sufficient Condition for the Equality of*

$$\frac{d}{dy}\int_a^b f(x.y)dx \text{ and } \int_a^b \left[\frac{d}{dy}\{f(x.y)\}\right]dx$$

B. M. GUPTA: *On the Relationship Between the Soluble Fatty Acids and the Potash Equivalent of Acids giving Barium Salts.* A. C. CHATTERJI: *Influence of Lyophillic Colloids on the Wettability of Naphthalin.*—The power to wet and the protective effect of lyophillic colloids bear a very close relation to each other, both being due to absorption of the colloid by the respective particles.

Indian Chemical Society:

October 1935. HANS KRALL AND RAMESWAR DAYAL GUPTA: *The Phenylthiocarbamides.—A Contribution to the Study of the Triad,-N-C-S—. Part I.—Aniline Thiocyanate.* SANATSARAN MEHTA AND HANS KRALL: *The Phenylthiocarbamides.—A Contribution to the Study of the Triad.-N-C-S-.—Part II.—Action of Hydrolytic Agents on Phenylthiocarbamide.* SANATSARAN MEHTA AND HANS KRALL: *The Phenylthiocarbamides.—A Contribution to the Study of the Triad. —N-C-S-.—Part III.—Action of Nitrous Acid on Phenylthiocarbamide.* DINES CHANDRA SEN: *Studies in the Camphor Series.—Part I.* L. MCMASTER AND C. R. NOLLER: *The Formation of Amides from Nitriles by the Action of Hydrogen Peroxide.* H. K. SEN, KANAILAL ROY AND PANKOJ ROY: *Note on a Routine Gas Analysis Apparatus.* SISIR KUMAR GUHA: *Studies in Indigoid Dyes.* UMAPRASANNA BASU AND BASUDEB BANERJEE: *Synthesis in the Pyridine Series. —Part II.* NIRMALAPADA CHATTERJEE: *The Coagulation of Ferrocyanide Sols Containing Varying Amounts of Potassium Ferrocyanide.* B. B. DEY: *Preparation of Resorcinol Monomethyl Ether* (*A Correction*).

Asiatic Society of Bengal:

November 1935. (MEDICAL SECTION). *Live fishes inspected in the food and air passages of man.*—At the recent Meeting of the Medical Section of the Asiatic Society of Bengal, Dr. S. L. Hora of the Indian Zoological Survey addressed the members on the recent Indian cases of live fish found in the human pharynx and air passage. The Surgical aspect of such cases was presented by Lt.-Col. B. G. Mallaya. Dr. E. W. Gudger had reported 38 cases of live fish impacted in the pharynx and air passage, which were compiled from records covering the period from 1567 to 1933. Nearly 32 per cent. of such accidents are

said to have occurred in India and Burma. Dr. Hora instituted further enquiries into such calamitous occurrences and has collected information regarding 19 more cases; altogether there have been 31 authenticated reports of such accidents in India. On mapping out the distribution of these misfortunes according to the provinces where they occurred and according to the types of fish producing them, Dr. Hora has placed the latter in the following order of delinquency.—*Anabas testidinens* responsible for 17 cases; *Colisa Fasciatax*, 4; *Mustacembelus*, *Nandus* and *Cynoglossus*, 1 each; 7 undetected. Out of the 19 recent cases, the Madras Presidency claims 6, Assam 5, Burma and Bihar and Orissa 3 each, Bengal and Bombay Presidency 1 each. In Dr. Gudger's Indian cases, the offending fishes were found in the pharynx of the victims; Dr. Hora reports that in 13 cases, fishes were lodged in the food passage and in 6, he found them insinuated in the air passage: more than 63 per cent. of these cases proved fatal.

Dealing with the surgical treatment of fish obstruction Lt.-Col. Mallaya observed that the condition of the patient and the position of the fish must determine the line and the extent of operative interference. A foreign body blocking the vital passages must rapidly produce suffocation and Dr. Mallaya suggested that in view of the extreme urgency of all such cases, a tracheotomy or pharyngotomy performed even with a pocket knife would relieve respiratory embarrassment, and in other less desperate cases where only the nasopharyngeal passage is affected, perhaps a pair of long forceps might suffice to provide relief. The removal of the fish from the passages must be at once delicate and difficult for the obvious reason that the animal may remain alive for some time and may be bristling with spines. Accidents of this kind must be due to follies. Further history of such cases of live fish being impacted, regarding age, sex and occupation of the victims must throw light upon the immediate causes of accidents.

Meteorological Office Colloquium, Poona:

Four meetings were held during November 1935. At the first of these held on the 4th, Father M. Selga of the Phillippines Weather Bureau addressed the gathering on "Typhoons and Weather in the Phillippines" and described the organisation of the Weather Service in the Islands; also, Father R. Raphæl of the St. Xavier's College, Bombay, who was in Quetta at the time of the big earthquake, gave an account of some personal impressions in respect of the same. The programme at the three remaining meetings was as follows:—

12-11-35.—Mr. P. K. Raman: "Some recent work on problems relating to the thermal balance at the earth's surface."

19-11-35.—Dr. S. K. Banerji: "Calculation of velocity and acceleration of a system of isobars."

26-11-35.—Mr. M. S. Katti: "Some recent work on meteorology in relation to the soil."

University and Educational Intelligence.

Andhra University:

Applications will be received by the Registrar Andhra University, Waltair, for the following posts in the University Colleges:—

Professor of Economics.
Professor of Politics.
Professor of Pure Chemistry.
Professor of Applied Chemistry.

Salary Rs. 800—50/2—1,000.

The Syndicate will be prepared to consider higher terms in exceptional cases. Further particulars can be had from the Registrar.

Sir J. C. Coyajee, Professor of Economics, has resigned his appointment. He was Professor of Economics for nearly three years.

A Diploma course in Librarianship has been introduced in the University.

The M.A. (Hons.), M.Sc. (Hons.), and Ph.D. degrees were awarded for the first time this year, to candidates for research work done by them.

Allahabad University:

Pandit Iqbal Narain Gurtu was elected Vice-Chancellor of the Allahabad University, at a meeting of the Council held on the 4th December.

Aligarh Muslim University.

The Academic Council of the Aligarh Muslim University decided at its meeting held on 13th November to accept the thesis submitted for the Ph.D. Degree in Physics by Mr. Mohd. Jan Khan. As examiners Sir C. V. Raman, Dr. W. Jevons, Imperial College, London, and Prof. R. Samuel, Aligarh, have been appointed. The thesis comprises two parts. In part I, the candidate has worked out the absorption spectra of a number of polyatomic molecules and shows that the ground state of molecules formed by a central atom in a higher state of valency does not arise from the ground state of a molecule formed by atoms of lower valency but from an excited level. The second part deals with the spectra of SeO and SeO_2, the vibrational analysis of which is given. The constants of these molecules show a close correspondence. Both these results clearly indicate a strong localisation of the bonds.

Benares Hindu University:

New Appointments.—In the new session which commenced in July, eleven new appointments were made. The following are some of the important ones:—

(1) Rao Bahadur K. V. Rangaswami Aiyangar, M.A. (Madras), appointed Principal of the C. H. College of Arts and University Professor of Economics.

(2) Dr. S. K. Belvalkar, M.A. (Bom.), Ph.D. (Harvard), I.E.S., appointed University Professor of Samskrit.

(3) Dr. P. N. Roy, M.A. (Cal.), D.Litt. (Rome), appointed Professor of Modern European Languages.

(4) Dr. Mrs. Indumati B. Adarkar, M.B.B.S. (Bom.), D.L.O., M.R.C.S. (London), appointed Lecturer in Domestic Science for the Women's College.

Faculties.—At the Annual Meetings of the Faculties held on November 29 and 30, 1935, the following gentlemen were elected Deans :—

Faculty of Law : The Rt. Hon'ble Dr. Sir Tej Bahadur Sapru, K.C.S.I., M.A., LL.D.
Faculty of Arts : Prof. P. B. Adhikari, M.A.
Faculty of Science : Prof. P. K. Dutt, M.A. (Cantab.)
Faculty of Oriental Learning : MM. Pandit Pramatha Nath Tarkabhushan.
Faculty of Theology : Pandit Vidyadhar Gaud.
Faculty of Ayurveda (Medicine and Surgery): MM. Kaviraj Dr. Gananath Sen, M.A., M.D., L.M.S.

Academic Questions.—The University was one of the earliest in the country to start a number of technical and professional courses which have hitherto been under the Faculty of Science. With a view to greater efficiency the Senate has proposed the establishment of a separate Faculty of Technology. The necessary Regulations have been framed and submitted to the Visitor for sanction. The Senate has also under consideration the introduction of a diploma course in Pharmaceuticals.

University Library.—The University Library is now housed in a commodious and magnificent building constructed at a cost of Rupees Three Lakhs which was received as a donation from H. H. The Gaekwad of Baroda. During the year 1934–35, 8,547 volumes were added bringing the grand total of books to about 80,000. The new accession includes 5,725 volumes valued at Rs. 50,000 and received as a gift from the Kanju Mulji Charitable Trust of Bombay.

The University Training Corps.—The corps has returned from the Annual Camps of the Battalion held at Bareilly from Nov. 1 to 15. It won the Efficiency Cup for the ninth time in succession and annexed several other prizes and trophies. Besides providing armoury, parade ground and residential quarters the University has recently constructed a 400 yards' classification Shooting Range at a total cost of Rs. 6,000.

University of Bombay:

Royal Institute of Science.—Dr. Mata Prasad, Professor of Inorganic and Physical Chemistry, has been elected a Fellow of the National Institute of Sciences, India.

The 1st annual meeting of the Indian Academy of Sciences, was held here from 18th to 20th of December. It was opened by H. E. the Governor of Bombay. Mr. V. N. Chandavarkar, the Vice-Chancellor of the Bombay University, was the Chairman of the Reception Committee.

Calcutta University:

The Senate of the Calcutta University has donated Rs. 5,000 to the Indian Institute of Medical Research, out of the Sir P. C. Roy Fellowship Fund, and sanctioned a grant of Rs. 1,200 to Dr. G. N. Roy, Professor of Chemistry, Carmichæl Medical College, to enable him to carry on research on Epidemic Dropsy.

University of Mysore:

1. The Senate held its ordinary meeting for the year on 21st November, 1935. At the meeting, the Senate resolved to recommend the conferment of the Degree of Doctor of Laws on Rajasabhabhushana Diwan Bahadur Sir K. P. Puttanna Chetty. A proposal to declare the results of the Master's Degree examination in two classes (first and second) was referred to the Academic Council. A proposal to institute a section providing balanced diet in hostels was discussed. The University authorities will further consider the proposal.

2. Dr. A. Subba Rau, B.A., D.Sc. (Lond.), F.R.M.S., Professor of Physiology, Medical College, was elected by the Senate of this University as its representative on the Court of the Indian Institute of Science, Bangalore, for the period, 1936–40.

3. The following Extension Lectures were delivered :—

(i) Mr. Devudu Narasimha Sastry, M.A., on (*a*) "Kalidasana Sandesa"; (*b*) "Karnataka Samskruti"; in Kannada at Nanjangud, Mysore and Chickballapur.
(ii) Mrs. Iqbalunnisa Hussain, B.A., Dip.Ed. (Leeds). on (*a*) "My experiences in an English University" in English at Bangalore and Mysore; (*b*) "Education of Muslim Women" in Urdu at Bangalore and Channapatna.

4. Mr. K. S. K. Iyengar, B.A. (Cantab.), Professor of Mathematics, Central College, proceeded on leave for one month and 18 days from 6th November, 1935.

Central Board of Education:

FULL LIST OF MEMBERS.

Ex-officio.—(1) Sir Girja Shanker Bajpai, Member-in-charge of the Department of Education, Health and Lands (Chairman), and (2) Sir George Anderson, Educational Commissioner with the Government of India.

Nominated by the Government of India.—(3) Sir T. B. Sapru, (4) Sir Akbar Hydari, (5) Dr. A. H. Mackenzie, (6) Right Rev. G. D. Barne, (7) Lady Grigg, and (8) Srimati Rajkumari Amrit Kaur.

Elected by the Council of State.—(9) Sir K. Ramunni Menon.

Elected by the Legislative Assembly.—(10) Dr. Ziauddin Ahmed, and (11) Dr. Bhagwandas.

Nominated by the Inter-University Board.—(12) Mr. Shyamaprasad Mookerjee, Vice-Chancellor, Calcutta University, (13) Sir S. Radhakrishnan, Vice-Chancellor, Andhra University, and (14) Dr. R. P. Paranjpye, Vice-Chancellor, Lucknow University.

Representatives of Local Governments—Either the Minister of Education or his deputy, Director of Public Instruction or his deputy.—(15) The Director of Public Instruction, Madras, (16) the Director of Public Instruction, Bombay, (17) the Minister-in-charge of Education, Bengal, (18) Sir J. Srivastava, Minister of Education, United Provinces, (19) the Director of Public Instruction, Punjab, (20) Dr. Ba Maw, Minister of Education, Burma, (21) the Minister of Education, Bihar and Orissa, (22) Mr. B. G. Kharpade, Minister of Education, Central Provinces, (23) the Director of Public Instruction, Assam, and (24) the Director of Public Instruction, North-West Frontier Province.

Reviews.

"Mathematics and the Question of Cosmic Mind," with Other Essays. By C. J. Keyser. ("Scripta Mathematica", Yeshiva College, Amsterdam Avenue and 186th Street, New York, U.S.A.) 1935. Pp. 128. 75 cents.

This book is No. 2, in the Scripta Mathematica Library series of which No. 1 was reviewed in these columns previously. According to the author the book, at least the greater part of it, is written for those who should like to think, and not for the multitude who are satisfied with being merely told. The volume is composed of six essays,—all reprints,—two being popular expositions of the mathematical method and one a popular discussion of that most discussed subject—whether the external world is real. In the essay on "Mitigating the tragedy of our modern culture" the author puts in a powerful plea for more earnest attempts on the part of the specialists to popularise their work so as to reach "the intellectual laymen" and reviews the notable attempts of Reichenbach, Weyl, Lewis, Levy, Jeans and Eddington. It certainly gives us great pleasure to add to these the name of the eminent author of these essays. In the essay dealing with Law (he calls it legal science), we are shown how mathematising will benefit the subject immensely though there are obvious limitations of a formidable character. The last essay is merely an appreciative article on the life of the late Prof. W. B. Smith, a great mathematician and a versatile scholar.

The book is well got up notwithstanding the misprints which occur (*e.g.*, on pages 56, 89, etc.) and is very readable, the language throughout being frankly journalistic. The purpose of the promoters of the movement is eminently served by the two books so far issued and we may confidently look forward to more illuminating works of a similar nature in future. As No. 1 in the series bears the name *Poetry of Mathematics and Other Essays*, it would not have in the least been inappropriate if this had been named *Meaning of Mathematics and Other Essays*.

B. M. N.

Mechanical Properties of Matter. By S. G. Starling, B.Sc., A.R.C.Sc., F.Inst.P. (Macmillan & Co., Ltd., London.) 1935. Pp. viii + 336. Price 6*sh*.

There are but a few text-books on Properties of Matter at present available in English and a new book by the author of the much-used *Electricity and Magnetism* is a welcome addition. The book comes entirely up to our expectations and has the same conciseness and clarity that distinguish the other books of the author. Though primarily meant for Higher School Certificate and Intermediate students, such free use of simple Calculus has been made that with a very few additions here and there, *e.g.*, in connection with Gravitation, the book will meet the utmost needs of the B.A. and B.Sc. Pass students of our Universities. In fact the chapters on "Flow of Liquids and Gases" and "Waves" contain more information than is usually required from such students and help to put them in touch with useful results in Hydrodynamics deduced in a simple way. The large number of graded exercises appended to the several chapters will serve to give the student a thorough grounding and the really numerous worked examples are models which can be entirely recommended.

Exception has to be taken, however, to one or two features in this otherwise excellent book. The half-hearted introduction of vector notation leads to some equations which are meaningless. The fault is mostly due to introducing division by a vector as if it were an ordinary scalar. Thus $\frac{u_2'-u_1'}{u_1-u_2}=e$ on p. 30, $f \times s$ meaning fs on p. 31 and $\frac{\mathrm{v}^2}{r}$ on the same page will lead the student to an unwarranted liberty in operations with a vector. On p. 77 $\frac{v^2}{r}$ is called the radial acceleration: this is misleading. $\frac{v^2}{r}$ is the acceleration along the normal which happens to coincide with the radius in the case of the circle. The equation $\frac{d\mathrm{v}}{dt}=r\frac{d\omega}{dt}+\frac{\mathrm{v}^2}{r}$ on p. 76 would mean that along the radius there are two accelerations $r\frac{d\omega}{dt}$ and $+\frac{\mathrm{v}^2}{r}$ both of which are false conclusions. The introduction of the vector notation is a progressive step, but the little addition that would make the notation consistent is not beyond the grasp of the students who use the book, and could easily be introduced. On p. 96 there is a misprint reading "holes are drilled the bar" and on p. 175 we once read "liquified". The

correction for the buoyancy of air in weighing should be $m_1 = m_2\left(1 - \frac{\delta_3}{\delta_2} + \frac{\delta_3}{\delta_1}\right)$ while on p. 165 it is written as if $m_1 = m_2\left(1 - \frac{\delta_3}{\delta_1}\right)$.

These small blemishes are indicated with the sole idea of making the book as unexceptionable as possible, for we may be sure that such a good text will see numerous editions and will serve generations of students. We have no hesitation in recommending the book to the Pass students of our Universities. The low price is most inviting.

T. S. S.

Elements of Strength of Materials. By Messrs. S. Timoshenko and Gleason H. MacCullough. (Messrs. Macmillan & Co.) 1935. Pp. 350. Price 14*s*.

The authors have brought out an exceedingly useful book. There are a large number of text-books on the subject but the presentation of the subject by the authors is so good that one's interest to read the book is increased as he proceeds and at the same time, due to the inclusion of alternative methods of solving many of the problems the subject is made very clear. The authors have in addition included at the end, chapters on " Energy of Strain " and on the various modern strength theories which will give just an idea to the students about the practical realities of the strength of materials and working stresses. But in the chapter on riveted joints while discussing the failures of joints by various causes, they have recommended that the distance between the centre of the hole and the edge of the plate should be between $1\frac{3}{4}$ to 2 times the diameter of the rivet, while the British practice recommends only $1\frac{1}{2}$ times the diameter. Again, for double shear the resistance is assumed to be double that for single shear, while the usual practice is to assume only $1\frac{3}{4}$ times that of single shear resistances, since it is not possible to ensure uniform distribution of loads. The authors could have, with benefit, included the formulæ for the design of rivets for given thickness of plates and design of cover plates in the case of butt joints, and also graphical determination of pitch by band method. Except for these shortcomings the book is a very good one and can be used as a text-book in the Colleges and Schools of Engineering.

The Publishers must also be congratulated on the neat printing and get-up of the book; there are very few errors and the printing is such as not to strain the eyes.

E. K. R.

Mercury Arc Rectifier Practice. By Mr. F. C. Orchard, A.M.I.E.E. (Chapman & Hall, Ltd., London.) 1935. Pp. 224. Price 15 *sh.*

This book deals clearly and concisely with a subject of growing importance, and will be found equally useful by students as well as practising engineers. The author explains in simple terms, with the help of clear diagrams, the principles underlying the action of the rectifier, its evolution and construction. The writer also deals in a very practical and comprehensive manner with the installation, operation, maintenance and testing of rectifier sub-stations. The chapter on grid control indicating, as it does, some important applications and possible lines or future development, adds greatly to the value of the book. The diagrams are excellent. The concluding chapter gives the relative advantages and disadvantages of the rectifier as compared with rotating machinery for sub-station work. The appendix contains some useful tables and a bibliography is added.

C. A. K.

Inorganic Colloid Chemistry, Vol. II. The Hydrous Oxides and Hydroxides. By H. B. Weiser, Professor of Chemistry at the Rice Institute. (John Wiley & Sons.) 1935. Pp. 429. Price 23/6.

The book deals with the methods of preparation, the properties and the uses of oxides and hydroxides in the colloidal condition. Ten years ago the author published a book on the Hydrous Oxides. The present volume, however, is not a mere revision of the earlier work. As stated by the author in the preface, most of the chapters have been entirely rewritten embodying the latest developments in this rapidly expanding branch of physical chemistry. The numerous observations recorded in the book have been examined critically and special emphasis has been laid on those aspects of the study of colloidal oxides as have led to the development of colloid chemistry on the theoretical as well as the applied side.

The first chapter is introductory in nature and deals in general with the preparation and properties of hydrous oxides and gels. The oxides are studied in detail in the subsequent chapters. The treatment of the hydrous oxides of iron, aluminium, chromium and

silicon is particularly exhaustive. The last four chapters deal with the technical applications of the hydrous oxides in mordant dyeing, mineral tanning and water purification.

The book is to be welcomed as a valuable reference work by colloid chemists and will be equally useful to the teachers and students of chemistry as the information is presented in a clear manner — characteristic of all the publications by Professor Weiser.

B. S. RAO.

Colloids in Agriculture. By C. E. Marshall, M.Sc., Ph.D. (Edward Arnold & Co., London.) 1935. Pp. 184. Price 5*s*.

The publication of this book is a sign of the increasing extent in which the teachings and methods of physical chemistry and of colloidal science are being drawn upon in building up the scientific basis of the studies of soil. Dr. Marshall's work on soil problems specially that on the X-ray analysis of clay minerals is well known and the book fulfils every expectation as to a clear, critical, concise and accurate exposition of the subject-matter. The book has been written with an eye to the requirements of "country organisers, district lecturers and rural instructors—indeed, to all who are engaged in scientific agriculture and who are interested in the application of our latest knowledge to their field work and their teaching" as also of "agricultural students"; in other words, both for instructors and students. It serves this purpose most admirably. In the short compass of 184 pages, demy size, the subject-matter is treated under the heads, the nature of colloids, the formation of colloids, the properties of small particles in suspension, the properties of molecules at surfaces, ions at surfaces, soils and gels, the mineral colloids of soil, the organic colloids of soil, colloids in soil formation processes, colloids and soil texture, some colloidal materials present in living organisms, colloidal architecture in biological structures, milk and milk products as colloidal systems, smoke damage and plant protection. The book incorporates the latest information though naturally it is possible to indicate only the broader principles in so short a space. It has also the merit of using a lucid and descriptive style and avoiding such intricacies as are unsuitable for the class of readers the author has in view. It seems, however, that the student, in order to intelligently grasp the subject, must have a good knowledge of the fundamentals and of more complicated allied phenomena which would supplement the skeletal framework given in the book. This need is met by the author by the addition of lists of reference books at the end of each chapter with short notes for guiding the student.

The appearance of this book following in close succession those of Professors Robinson and Comber and the latest edition of Sir John Russell's well-known book now places at the disposal of English-knowing students of soil science an excellent account of the present position of our knowledge and tendencies of the development of soil science.

The reviewer was particularly interested to notice that the book correctly reflects the present position of our knowledge regarding the following:

(*a*) Coagulation by electrolytes seldom takes place at the isoelectric point and quite often at a cataphoretic speed higher than that of the particles of the sol not mixed with an electrolyte. It may be mentioned that during the aggregation of the particles the cataphoretic speed most often rises and then sharply falls when the colloidal solution loses a visible homogeneous appearance. The text-books on colloids give a wrong picture in this respect.

(*b*) An electric double layer may be formed on the surface of a particle by the adsorption of ions as distinct from the dissociation of adsorbed or surface molecules already present. It may be stated that this idea of dissociation of surface molecules requires to be supplemented by an answer to the question as to why a part of the dissociated molecules remains attached to the surface and the other part is, relatively speaking, more able to diffuse into the liquid and give rise to the double layer. The use of the terms, mobile ions and primary adsorption, is also specially welcome to the writer. They give a better idea of the conditions obtaining in the double layer. Perhaps the mention of the electrical adsorption would have given a more definite picture of the double layer. The subjects of the adsorption of ions, and of base saturation capacity, and the degree of saturation in relation to texture, pH and the Hissink, T, S, and V values might have been treated somewhat more in detail.

No student of agriculture can afford to do without a copy of this book.

J. N. M.

Annual Review of Biochemistry, Vol. IV. Edited by James Murray Luck. (Annual Review of Biochemistry Ltd., Stanford University P.O., California, 1935.) Pp. vii + 639. Price $ 5·00.

The policy adopted by the *Review* is neither to encompass the whole field of Biochemistry within a single volume nor to adhere rigidly year after year to a given list of topics, but to discuss a bunch of papers relating to a definite aspect of Biochemistry or to a certain point of view. The chemistry of proteins and amino acids reviewed by Professor Cohn is a fine example of how stray and apparently unrelated papers have been marshalled and integrated to yield a comprehensive and a stimulating review of the subject from a physiochemical standpoint.

The Editors have been fortunate in securing the services of several authorities in their respective fields and this circumstance while raising the prestige of the *Review*, renders it highly informative and inspiring. Such reviews are useful in acquainting the reader with the processes which lead to the creation of new knowledge and by way of example particular attention may be drawn to the reviews on Plant pigments by Kuhn, Alkaloids by Robinson, Growth substances in plants by Thimann, Vitamins by Harris and Chemical embryology by Needham. While the Editors of the *Review* have provided us such a substantial quantity of useful information which will stimulate and inspire further inquiry, it may be considered ungrateful if we remark that some of the reviews read more like an assemblage of chemical abstracts. In future, with enlistment of the co-operation of the reviewers it should be possible to achieve the difficult task of maintaining a uniformly high standard and quality for all the branches of the subject reviewed.

The fact that the enterprise after the introductory three-year period, has been established as a non-profit corporation, is a fine testimony to the excellence, usefulness and popularity of the *Review*. It is a volume which will be found indispensable to every research worker.

M. S.

Cane Sugar Factory Control. By K. C. Banerji, F.S.T.A. (Indian Press, Ltd., Allahabad.) 1935. Pp. 436. Price, Foreign £ 1 ; Indian Rs. 13–8–0.

This book is divided into two parts. The first part contains fifteen chapters on the technical methods of chemical control and their principles, special reference being made to the recommendations of the "Uniformity Committee". The second part is a collection of 42 tables useful in the routine as well as special factory control work.

The official definitions of the "Uniformity Committee" are given in the first chapter with the author's explanatory notes wherever necessary. A separate chapter on sampling and weighing has been written. The methods of drying for moisture determination are treated in detail. The chapter on polariscope contains a concise explanation of the principles of polarisation, and a description of the different instruments and accessories.

Lane and Eynon's method for reducing sugars has been recommended for all determinations except for high grades for which Low's method should be employed. The description of both the volumetric and gravimetric methods for reducing sugars is full but the argument for including, in the same chapter, methods of ash determination is not convincing.

For mill control purposes, Noel Deerr's formula for the weight of mixed juice any other unknown quantity in the fundamental equation, has been favoured. The author has given a detailed description of Deerr's algebraic theory and concludes the chapter with a numerical example and the standard milling formulæ.

The chapter on boiling house control is well written. It contains the s.j.m. and the Winter-Carp-Geelig's formulæ and the different expressions for the "recovery" and "yield". Calculation is amply illustrated by numerical examples.

In spite of the numerous errors in the text, which are of a minor character and are incidental to a first publication, the subject-matter of the book is very well arranged and the finish given to it is quite up-to-date. The illustrations are apt and the compilation of tables quite comprehensive. With the latest informations like the International Committee recommendations, pH control, method of colloid estimation, etc., the book satisfies a real need of every sugar factory laboratory.

G. G. RAO.

The Bombay Grasses. By E. Blatter, S.J., Ph.D., F.L.S. and C. McCann, F.L.S. (*Scientific Monograph* No. 5, of the Imperial Council of Agricultural Research.)

The late Father Blatter was one of the most untiring of workers and one of the most prolific writers in the field of systematic botany in Western India for many years. Mr. McCann had during a long period collaborated with Father Blatter and this work, which appears above their joint names, represents an enormous amount of very careful labour in the field, the herbarium and the library. The bibliography is a complete list of references to grasses. The authors have wisely followed Stapf in the definition and sequence of the various divisions of the grasses and in this respect and others the book is up-to-date. The ecological side has not been forgotten and economic and medicinal uses are also mentioned, where known. A very valuable part of the book is composed of the excellent drawings done by Mr. R. K. Bhide, up till recently the Economic Botanist in the Nizam Dominions and previously a member of the Bombay Agricultural Department. A dissection under the dissecting microscope and a reference to these plates will often enable a quick diagnosis to be made—a diagnosis which might otherwise take a long time, particularly if some of the older descriptions have to be used for the identification of grasses.

As many of the grasses mentioned in this work are distributed widely over India, it is certain that the book will be in great demand by those who are interested in grass throughout the whole of the Indian Empire. While the book is primarily botanical and systematic, it will be found useful to those into whose spheres grasses come from the practical point of view, the workers in the Agricultural Department, the Forest Department, the Revenue Department, the scientific sections of Indian Universities and Colleges and the growing number of lovers of nature who are prepared to undergo the small discipline necessary to be able to follow a botanical description. A regrettable defect in this work is the binding, which is likely to give way at an early date and throughout the book the printer's ink appears to have been occasionally smudged.

W. B.

Birth Control To-Day. By Dr. Marie Carmichael Stopes. (John Bale Sons & Daniel Son, Ltd., 83–91, Great Tichfield Street, London, W. 1) 1934. Second Edition. Pages 237.

Since the publication in 1919 of *Wise Parenthood* Dr. Stopes has been contributing voluminously to the literature on contraception. In all her writings she has, to quote her own words, created a background of argument and sentiment behind the scientific exposition. The present book, which is addressed to those converts to Dr. Stopes's doctrines, who want a practical solution to their problems, is entirely devoid of sentiment and presents merely the essential facts about birth control in all its aspects.

At the outset the author cautions against those who, wilfully disregarding the fundamental teachings of contraception, resort to unnatural methods, and as a consequence wreck their own lives and are a menace to society as a whole. The book begins with laying before the reader the case for birth control and the relevant physiological facts. A unique feature of the book is that side by side with the orthodox methods some very efficient and cheap makeshifts have been indicated. It is very gratifying to note that in this particular, if in no other, the author's claim for the usefulness of the book to the less favoured section of our society is thoroughly justified.

The rapid spread of birth control knowledge in modern times has brought in its trail certain baneful results. In the hands of the ignorant, the methods of birth control are at once dangerous and undesirable. The author is keenly alive to this, and has, in a special chapter, dealt in an admirable manner, with the so-called "dangerous" methods. This section above all others must form the subject for serious study. That it is impossible to divorce sentiment entirely from such a human consideration as contraception is evident from the subject-matter of the ninth chapter; here the author has answered certain questions arising in the minds of persons troubled by qualms of conscience. These we hope will be useful in setting at rest all doubts of honest thinking folk. The value of the book is considerably enhanced by the inclusion, at the end, of some useful information about the working of Birth Control clinics and directions for the obtaining of first-hand knowledge. A short note appears about the legislation governing the practice of Birth Control by individuals and at clinics.

Admittedly it is the right of every individual to be equipped with the knowledge to control his most vital function and the publication of this book by a recognised authority is very opportune at a time when

the Public Health Commissioner in India has put up a plea for the control of population in this country.

C. N. R. R.

The Snakes of India. By Lieut.-Colonel K. G. Gharpurey, I.M.S. (The Popular Book Depot, LamingtonRoad, Grant Road, Bombay.) 1935. Pp. x + 165. 76 Figures. Price Rs. 3.

Gharpurey's *Snakes of India* is a popular book giving general information and useful knowledge about the various common snakes found in our country and is written in a simple, lucid style, calculated to make the subject both attractive and comprehensible to the layman. Beginning with a short Introduction, preceded by a page of "Errata" and quotation from Arnold's *Indian Idylls*, it comprises as many as 36 chapters dealing with almost every aspect of Indian Ophiology. The last chapter is by R. K. Golikere and makes a "World Survey of Dangerous Snakes". There are 76 figures, most of which are photographs. It is really unfortunate that in many cases the author has had to depend on photographs made from distorted, preserved specimens and has not been able to secure characteristic pictures of *live* specimens. A preserved specimen loses the pose, attitude and bodily configuration characteristic of a living one, and a picture made from it cannot give a faithful idea to the reader.

Here and there, though rather rarely, one comes across in Gharpurey's book facts which appear to be imprecisely expressed; but a book of such wide scope cannot be absolutely without faults and we can conscientiously recommend it to those who are interested in the subject.

As examples, we might mention that the author says, "in the majority of snakes, the female lays eggs *in the sun*" (p. 5; italics ours), a statement which we cannot endorse. On p. 6 he says that "the safest way to hold a snake is by its tail at arm's length. Then it may wriggle but cannot bite or twist round the arm." One might mention that snakes are supple creatures and even though they are gripped by the tail and kept at arm's length from the body, they can raise up their front half of the body by making a sort of loop and bite at one's hand. What the snake-charmers do is not only gripping a snake as described by the writer, but also continually giving it a gentle shake to prevent its reaching up.

On p. 49, Gharpurey says, "Snake-charmers ....are adroit in catching snakes. They are quick, and as soon as they see a snake, they grab it just behind the head, so that it cannot bite." The reviewer has accompanied snake-charmers once annually for the last nine years on snake-hunting in the jungles, but he has yet to see a snake-charmer who can grab a poisonous snake just behind the head, as soon as he sees it. If he did it, in all likelihood he would not live long to exhibit that snake to admiring spectators. Usually, the snake-charmer—and not all snake-charmers—can catch cobras fresh from the jungle—drags out a cobra from its hiding-place by the tail, keeps it at a yard's distance from his body, places a stick on its neck and by moving the stick carefully round, "pins" the head firmly to the ground. Then and only then it is that he ventures to grip its head in his hand. With a krait the process is doubly more difficult and it is only the most adroit snake-charmer who would try his hand at it.

On p. 4, the author says that "the bifid tongue probably conveys the sense of smell to the two nostrils". While this may be the usual idea, we should like to point out that one authority at least (Ditmars, 1922) believes that "*snakes hear with their tongues*" and that "the delicate, nerve-supplied tips of this wonderfully specialised organ are highly sensitive to vibrations from even slight sounds."

B. C. M.

Manual of Human Physiology. By Sir Leonard Hill, M.B., LL.D., F.R.S., HON.A.R.I.A. (Edward Arnold & Co., London.) 1935. Fourth Edition, 484 pages with 186 diagrams. Price 6*s*. 6*d*.

The fourth edition of this excellent and popular manual of Human Physiology follows closely the pattern of the preceding one but is modified in accordance with recent discoveries. An important feature of the book is the inclusion of a much-needed chapter on Reproduction; it also contains suggestions for experiments with very simple and inexpensive apparatus. It is as complete and clear an account of Human Physiology as could be written for the use of "students training to qualify as teachers; for nurses undergoing hospital training and for the higher classes of schools and polytechnics". The treatment of the subject on the whole is such that it will be of great help to any

one interested in the teaching of elementary Physiology. There is an adequate index.

A. S. R.

Further Experiments upon the Water-Gas Process. By J. G. King, B.H. Williams, and R. V. Thomas. (Department of Scientific and Industrial Research. Fuel Research. Technical Paper No. 43, 1935.)

This publication is a sequel to the earlier studies in which methods were described to study the carbon and thermal balances in producer-gas process.

The investigations described in this paper are arranged in four parts. The first part is devoted to a study of the causes of clinker formation in the generator and the devices employed to minimise the accumulation of clinker, especially such as would adhere firmly to the walls of the generator and cause serious inconvenience. Observations of the distribution of temperature at various regions of the fuel-bed, as well as of the velocity of flow of gas at the sides and central regions of the generator provided data which suggested (*a*) that while charging the generator, a device should be employed to keep the larger lumps of coke in the centre and let the coke breeze pack the sides, and (*b*) that the grate should be so arranged that air flows into the fuel-bed at the centre of the grate. These two devices helped to keep the zones of high temperature in the fuel-bed in the centre, and to keep the walls relatively cool and also to prevent the coke-ash from overheating and lead to formation of large and hard masses of clinker. Such a generator was operated successfully for a considerable period with four different specimens of coke whose ash fusion temperatures (in a reducing atmosphere) ranged from 1200 to 1500° C.

The second part presents the results of investigations on the effect of the rate of blowing on the efficiency of the process. With the aid of general considerations from the thermal point of view of the reactions between air and carbon, and also of the conditions prevailing in the gas-generator, an equation has been developed to connect the efficiency of the process with the rate of blowing. Experimental studies with different rates of blowing were carried out with a view to ascertain the variation in composition of the blow-gas and also of the thermal losses incurred. The results obtained were in conformity with the theoretical considerations, *viz.*, the rate of blowing should be as high as practicable in order to reduce to a minimum the percentage of carbon monoxide and also to reduce thermal losses. It is at the same time necessary to regulate the period of blowing so as not to exceed the optimum temperature in the fuel-bed.

The effect of the size of coke on the efficiency of the process was studied systematically with reference to *effective surface*, *reactivity*, *time of contact*, composition of the gases obtained and thermal output. It was found that variations of the size of coke in the range 0·1″ to 3·0″ had no marked effect on the efficiency of the process.

The next point studied was the efficiency of the process when using different types of coke, *viz.*, vertical retort, horizontal retort and low-temperature coke. No significant variations were found, the process efficiencies being 72·4, 75·1 and 72·9 per cent. respectively.

The various sources of error which would tend to vitiate the results are examined in detail and presented in an appendix. These errors are small and are due to (*a*) hydrogen from sources other than the water-gas reaction, (*b*) nitrogen in the coke, (*c*) sulphur in the coke, (*d*) moisture in the air, and (*e*) dilution effects.

2—4 Jan. 1936—
All India Obstetric and Gynaecological Congress, 1936 (will be held at Madras).

1954-35.—Printed at The Bangalore Press, Bangalore City, by T. Subramania Aiyar, Superintendent, and Published by B. N. Sastri, M.Sc., A.I.C., A.I.I.Sc., for the "Current Science" Board of Editors, Indian Institute of Science, Hebbal Post, Bangalore.

The Passing Away of His Majesty King George V.

THE Royal Family of Great Britain and the whole Empire have suffered a grievous loss in the death of H. M. King George V, and the grief of the Queen and of the other members of the Royal Household must be inconsolable, but the thought that the whole nation irrespective of colour and creed stands by them in this hour of trial and calamity must assuage and sustain them in their sorrow.

We did not like the look of Reuter's news announcing King George's illness, when the people were warned that cardiac trouble had set in. His illness in 1928 must have worn out all the reserve of strength and any small distemper must naturally produce very grave effects.

His Majesty's rule extending over twenty-five years has witnessed great political vicissitudes, and the world went through unparalleled tribulations. During this momentous period of the world's history, the British Crown alone stood foursquare to all the winds that blew, and this is a remarkable testimony to the personal ascendency which His Majesty's simple life and great personal virtues had established in the hearts of his devoted and loyal subjects. His Majesty's rule was one for which few dynasties in Europe can furnish a parallel. During this eventful period science and letters progressed in a manner which few reigns have witnessed, and His Majesty's tender solicitude for the welfare and prosperity of the Great Commonwealth through scientific progress will be gratefully remembered by posterity. Edward VII was named The Peace-Maker, his illustrious son was a Peace-Lover whose efforts at promoting the peace of the world will form an illuminating chapter of the history of the times.

In the demise of His Majesty, King George V, the world has lost a great monarch, a devout Christian, and an estimable gentleman. We offer our respectful and sympathetic condolences to the bereaved Royal Family.

His Majesty King Edward VIII.

HIS Royal Highness the Prince of Wales has assumed the powers and duties of the King of Great Britain and the Dominions overseas and those of the Emperor of India. For the arduous responsibilities to which he has been suddenly summoned, His Majesty King Edward VIII has passed through a long period of intensive training, guided and inspired by his beloved father. Like the late King George V, the Prince of Wales was a naval officer, a student of the University of Oxford, and has widely travelled. But the greatest experience, which few of the recent British Monarchs possessed, fell to the lot of the new King. During the World War he served both in the Western front and Egypt, and witnessed what horrible troubles, miseries and sufferings a cataclysm of that magnitude implies. It will be remembered that in 1921 His Majesty visited India as Prince of Wales and his charming manners and urbanity won for him universal admiration, and most of all his great popularity amongst the student population was unrivalled.

H. M. King Edward VIII has an intimate knowledge of the labour problems and the demands of the industrial classes, and his recent and frequent tours in industrial areas have provided him with unique opportunities of studying them at first hand, and identifying himself with the poorer people. This is an indispensable equipment for every modern monarch for the success of his rule.

While we tender to His Majesty King Edward VIII our respectful sympathies for the great loss he has sustained, we offer our prayers to the Great Giver of all Good that He may shower His choicest blessings on the New King.

May His Rule be Long, Happy, Peaceful and Prosperous !

CONTENTS.

National Intelligence.

SIR GIRIJA SHANKAR BAJPAI, presiding at the inaugural meeting of the Central Advisory Board of Education held in December 1935, expounded the aims and objects of the Board in these terms :

"The main function of the Board is to impart to Educational thoughts the impulse of progressive policy. It is because we aimed at ensuring fruition of advice into action, that we invited ministers in charge of Education in Provinces to sit on the Board. It is because we aimed at viewing the whole field of Education in one conspectus, that apart from Education Ministers and their Directors of Public Instruction, we have invited the Inter-University Board to send us three representatives. It is because we want our effort to be quickened and influenced by responsible political opinion that we have with us representatives of the Legislature."

Presumably these ambitious sentiments must have formed the concluding portion of an important public pronouncement by the Member-in-charge of Education on the general policy of the Government of India, and it is widely hoped that the large and representative body of eminent Educationists and Legislators who compose the Board might ensure the progressive realisation of the high purpose adumbrated at the inauguration ceremony. It must be remembered that the Central Board is not a statutory body, and is without the power of taking the initiative in the formulation of any educational project or policy. Its function, therefore, is restricted practically to advising the Government of India on problems referred to it, or to inviting information from the Provincial Governments and other organisations interested in educational matters, with a view to examine the material collected in order to frame a co-ordinated scheme of recommendations. Manifestly the success of the Board in either of these spheres must depend on two fundamental factors. The first pre-requisite is the time and energy which the members of the constituent committees can devote to the study and investigation of the special and general problems coming within their purview and having a specific bearing on the development of cognate subjects in the more progressive countries, and how far the members will bring the results of such study and research to bear on the discussion of the questions referred to the Board. The second factor relates to the ability and willingness of the Provincial Governments to adopt the recommendations of the

whose broad outlook is reflected in the enlightened and progressive policy of his State. The knowledge and experience which he has accumulated during his extensive foreign travels must be an asset to the administration and his solicitude for the improvement of village life in Baroda is marked by the recent grant of a crore of rupees for rural uplift. This signal act, coupled with the opening of a new science and technological institute will earn for His Highness the enduring love and gratitude of his loyal subjects, than which nothing can be more gratifying to an Indian Prince. It is the earnest prayer of the people of Baroda as well as of those of the rest of India that His Highness Sir Sayaji Rao may be spared for many years to rule his State and support proposals for a progressive constitution in British India.

Dr. S. S. Bhatnagar, D.Sc., O.B.E. and Sir Bryce C. Burt, Kt.

WE have great pleasure in felicitating Dr. S. S. Bhatnagar and Sir Bryce Burt on the distinctions bestowed upon them.
